INTRODUCTION

TO THE ARTICLES RELATING TO ORGANIC CHEMISTRY.

In the present volume the nomenclature is the same as that adopted in the first volume. It has been explained in the Introduction to that volume, pp. viii-xiv. Thus, to take a single instance, the products of condensation between hydrazines and ketonic compounds are still called hydrazides, although Emil Fischer has, since the publication of the last volume, changed their name to hydrazones. Even supposing the latter name to be preferable, its abrupt introduction would greatly confuse the nomenclature by depriving it of uniformity.

Since the publication of the first volume I have been assisted in the work of reading and making abstracts of original memoirs by Drs. T. A. Lawson and Samuel Rideal, Messrs. J. Wilkie, J. T. Norman, V. H. Veley, G. N. Huntly, S. H. Collins, Dr. G. McGowan, and Mr. D. A. Louis. I have also been ably assisted by Mr. Arthur G. Green in the work of revising the proof sheets. I have great pleasure in thanking these gentlemen for the energetic and efficient manner in which they have carried out their share of the work.

H. Forster Morley.

Nomenclature of Ring Formulæ.

Hydrocarbons.

$C_6H_4<^{CH_2}_{CH}>CH$ *Indonaphthene.*

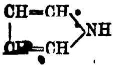
Trimethylene.

Tetramethylene.

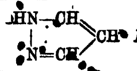
$CH_2<^{CH_2.CH_2}_{CH_2.CH_2}>$ *Pentamethylene.*

Tetramethenyl.

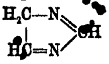
Nitrogen ring compounds.



Pyrrole or *Pyrrol.*



Pyrazole.



Metapyrazole.

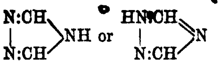
Glyoxaline.

$CH<^{CH-CH}_{CH=CH}>N$ *Pyridine.*

$CH<^{CH-N}_{CH=N}>CH$ *Pyrimidine.*

$CH<^{CH-N}_{N=CH}>CH$ *Pyrazine.*

Nitrogen ring compounds—cont.

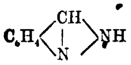


Triazole.

Osotriazole.

Tetrazole

$C_6H_4\left<\begin{matrix}CH\\NH\end{matrix}\right>CH$ *Indole.*

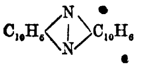


Indazine.

$C_6H_4\left<\begin{matrix}CH\\NH\end{matrix}\right>N$ *Pseudo-indazine.*

Acridine.

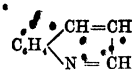
Phenazine.



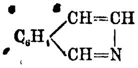
Naphthazine.

$N\left<\begin{matrix}CH-N\\CH=N\end{matrix}\right>CH$ *Triazoline.*

$N\left<\begin{matrix}N-N\\N=CH\end{matrix}\right>CH$ *Osotetrazole.*



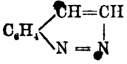
Quinoline.



Isoquinoline.

Quinoxaline.

Quinazoline.



Cinnoline.

Oxygen ring compounds.

Furfurane.

$C_6H_4\left<\begin{matrix}CH\\O\end{matrix}\right>CH$ *Coumarone.*

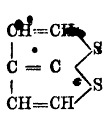
Oxazole.

$C_6H_4\left<\begin{matrix}NH\\O\end{matrix}\right>C_6H_4$ *Phenazoxine* or *Di-phenyl-oxazine.*

$CO\left<\begin{matrix}NH\\NH\end{matrix}\right>$ *Carbizine.*

Sulphur ring compounds.

Thiophene.



Thiophthene.

Thiazole.

$C_6H_4\left<\begin{matrix}NH\\S\end{matrix}\right>C_6H_4$ *Di-phenyl-thiazine (thiodiphenylamine* or *Imido-di-phenyl sulphide).*

$C_6H_4\left<\begin{matrix}N\\S\end{matrix}\right>CH$ *Methenyl-amido-phenyl-mercaptan.*

In many of the above formulæ the exact structure is not known; alternative ways of writing some of them will be found in vol. i. p. xii.

INITIALS OF SPECIAL CONTRIBUTORS.

H. B.	HARRY BAKER, Esq., F.C.S., *Chemist to the Aluminium Company, Oldbury.* Contributes CRYSTALLISATION.
F. W. C.	FRANK WIGGLESWORTH CLARKE, Esq., B.Sc., *Chief Chemist, United States Geological Survey.* Contributes ELEMENTS.
I. F.	MISS IDA FREUND, *Lecturer in Chemistry, Newnham College, Cambridge.* Contributes DENSITIES, RELATIVE.
A. G. G.	ARTHUR G. GREEN, Esq., F.I.C., *Research Chemist to the Atlas Works, Hackney Wick.* Contributes INDIGO.
D. H.	DAVID HOWARD, Esq. Contributes CINCHONA BARK.
J. J. H.	J. J. HOOD, Esq., D.Sc. Contributes EARTHS.
W. D. H.	W. D. HALLIBURTON, M.D., B.Sc., *Assistant Professor of Physiology at University College, London.* Contributes HÆMOGLOBIN.
F. R. J.	FRANCIS R. JAPP, M.A., Ph.D., F.R.S., *Assistant Professor of Chemistry at the Normal School of Science, South Kensington.* Contributes GLYOXALINES, HYDRAZINES, and HYDRAZONES.
G. M.	GEORGE McGOWAN, Ph.D., F.R.S.E., *Demonstrator in Chemistry at University College of North Wales, Bangor.* Contributes CHOLESTERIN.
F. W. R.	F. W. RUDLER, F.G.S., *Curator of the Museum of Practical Geology, London.* Contributes GEOLOGICAL CHEMISTRY.
I. R.	IRA REMSEN, Ph.D., *Professor of Chemistry in Johns Hopkins University, Baltimore.* Contributes EQUIVALENCY and FORMULÆ.
S. R.	SAMUEL RIDEAL, D.Sc., *Lecturer on Chemistry at St. George's Hospital Medical School.* Contributes FERMENTATION.
E. S.	DR. EDWARD SCHUNCK, Ph.D., F.R.S., *Manchester.* Contributes CHLOROPHYLL.
A. S.	ALFRED SENIER, M.D., Ph.D. Contributes CYANIC ACIDS.
C. O'S.	C. O'SULLIVAN, F.R.S., *Burton-on-Trent.* Contributes DEXTRIN.
J. J. T.	J. J. THOMSON, M.A., F.R.S., *Professor of Experimental Physics in the University of Cambridge.* Contributes EQUILIBRIUM, CHEMICAL.
[illegible] T.	R. THRELFALL, M.A., *Professor of Physics in the University of Sydney, N.S.W.* Contributes DISSOCIATION and EXPLOSION.
T. E. T.	T. E. THORPE, Ph.D., F.R.S., *Professor of Chemistry at the Royal School of Mines.* Contributes COMBUSTION and FLAME.
V. H. V.	V. H. VELEY, M.A., *Public Lecturer and Demonstrator in the University of Oxford.* Contributes FORMIC ACID.

Articles by Mr. MUIR are initialed M. M. P. M.

UNSIGNED ARTICLES are by Dr. MORLEY.

II. Terms and Quantities, &c., frequently used.

Aq.	Water; e.g. NaOHAq means an aqueous solution of caustic soda.
aq.	18 parts by weight of water.
A′ **A″** **A‴**	Residues of mono-, di-, and tri-basic acids. Thus, in describing the salts of a monobasic acid NaA', CaA'_2, AlA'_3 may be written, HA' standing for the acid. For a dibasic acid we should write Na_2A'', CaA'', $Al_2A''_3$ [illegible]
B′ B″ etc.	Stand for bases of the ammonia type, in describing their salts. Thus th hydrochloride would be $B'HCl$ or $B''2HCl$, according as the base monacid or diacid, &c.
conc.	Concentrated.
dil.	Dilute.
g.	gram.
mgm.	milligram.
mm.	millimetre.
mol.	molecule.
oil.	liquid, nearly, or quite, insoluble in water.
pp.	precipitate.
to ppt.	to precipitate.
ppg.	precipitating.
ppd.	precipitated.

sol.	soluble in.
insol.	insoluble in.
v. e. sol.	very easily
v. sol.	very
m. sol.	moderately } soluble in.
sl. sol.	slightly
v. sl. sol.	very slightly
v.	see.
cf.	compare.
c.	about.
[°]	a melting-point.
(°)	a boiling-point.
H.	Hardness (of minerals).
At. w.	Atomic weight.
Mol. w. or M. w.	Molecular weight.
D.	Density.
cor.	corrected.
uncor.	uncorrected.
i.V.	in vapour.
V.D.	vapour-density, *i.e.* density of a gas compared with hydrogen or air
S.G.	Specific gravity compared with water.
S.G. $\frac{10}{0}$	„ „ at 10° compared with water at 0°.
S.G. $\frac{15}{4}$	„ „ „ 15° „ „ „ „ 4°.
S.G. ^{12}	„ „ „ 12°; compared with water of which the temperature is not given.
S.H.	Specific heat.
S.H. v.	„ „ of a gas at constant volume.
S.H. p.	„ „ „ „ „ pressure.
H.C.	Quantity of heat, in gram-units, produced during the complete combustion of the mass of a solid or liquid body represented by its formula, taken in grams.
H.C. v.	Heat of combustion in gram-units of a gram-molecule of an element or compound, when gaseous, under constant volume.
H.C. p.	The same, under constant pressure.
H.F.	Quantity of heat, in gram-units, produced during the formation of the mass of a solid or liquid body represented by its formula, taken in grams, from the masses of its constituent elements expressed by their formulæ, taken in grams.
H.F. v.	Heat of formation of a gram-molecule of a gaseous compound from the gram-molecules of its elements under constant volume.
H.F. p.	The same, under constant pressure.
H.V.	Heat of vaporisation of a liquid, *i.e.* gram-units of heat required to change a gram-molecule of the liquid compound at B. P. into gas at same temperature and pressure.
T.C.	Thermal conductivity (unit to be stated).
S.V.	Specific volume; or the molecular weight of a gaseous compound divided by the S.G. of the liquid compound at its boiling-point compared with water at 4°.
S.V.S.	Specific volume of a solid; or the mass of the solid expressed by its formula, taken in grams, divided by its S.G.
E.C.	Electrical conductivity (the unit is stated in each case).
C.E. (10° to 20°)	Coefficient of expansion (between 10° and 20°).
S.	Solubility in water { of a gas = volume dissolved by 1 volume of water. of a liquid or solid = number of grms. dissolved by 100 grms. of water. In both cases the temperature is stated.
S. (alcohol)	„ „ alcohol
μ_β	Index of refraction for hydrogen line β.
μ_D, &c.	„ „ „ sodium „ D, &c.
$R_D\frac{15}{0}$	Molecular refraction for sodium light, i.e. index of refraction for line D minus one, multiplied by molecular weight, and divided by S.G. at 15° compared with water at 0°.
R_D	The same; S.G. being determined at 15°-20° and referred to water at 4°.
R_∞	The same for line of infinite wave-length, index being determined by Cauchy's formula (Brühl's R_A).
$[\alpha]_D$	Specific rotation for sodium light.
$[\alpha]_j$	„ „ „ neutral tint. $[\alpha] = \frac{100}{p} \times \frac{a}{d}$. a = observed rotation for 100 mm. of liquid. d = S.G. of liquid. p = no. of grammes of active substance in 100 grammes of liquid.

M. M.	Molecular magnetic rotatory power $= \frac{m \times \alpha}{d \cdot \alpha' \times m'}$, where m = molecular weight of the body of S.G. $= d$, α = angle of rotation under magnetic influence, α' = angle of rotation of water under same influence, and m′ = molecular weight of water (18).
Ac	Acetyl C_2H_3O.
Bz	Benzoyl C_7H_5O.
Cy	Cyanogen CN.
Et	Ethyl C_2H_5.
Me	Methyl CH_3.
Ph	Phenyl C_6H_5. } in formulæ.
Pr	Normal Propyl $CH_3.CH_2.CH_2$.
Pr	Isopropyl $CH(CH_3)_2$.
R, R′ &c.	Alcohol radicles or alkyls.
prim	primary.
sec	secondary.
tert	tertiary.
n	normal.
m, o, p	meta—ortho—para.
c	consecutive.
i	irregular.
s	symmetrical.
u	unsymmetrical.
ψ	pseudo.
ν	attached to nitrogen.
α, β, γ	Employed to denote that the substituent is attached to a carbon atom which is next, next but one, or next but two, respectively, to the terminal carbon atom. The end to be reckoned from is determined by the nature of the compound. Thus $CH_3.CHBr.CO_2H$ is α-bromo-propionic acid.
ω	denotes that the element or radicle which follows it is attached to a terminal carbon atom.
α, β, γ, &c.	indicate position in an open chain only.
1, 2, 3, &c.	indicate position in a ring only.
(α), (β), &c.	Used when α, β, &c. are employed in a sense different from the above, *e.g.* (α)-di-bromo-camphor.
	Baeyer's Nomenclature:
(*B.*)	benzene ring.
(*Py.*)	pyridine ring. Thus (*B.* 1:3) dichloroquinoline, means a meta-dichloroquinoline in which the chlorine atoms are both in the benzene ring. While (*Py.* 1:3) dichloroquinoline, means a similar body, only the chlorine atoms are in the pyridine ring. The numbers are counted from two carbon atoms which are in different rings, but both united to the same carbon atom.
(*A.*)	denotes the central ring in the molecule of anthracene, acridines, and azines.
eso-	means that the element or radicle it precedes is in a closed ring.
exo-	„ „ „ „ „ not in a benzene ring.
allo-	denotes isomerism that is not indicated by ordinary formulæ: thus maleic acid may be called *allo*-fumaric acid.
thio-	denotes displacement of oxygen by sulphur.
sulpho-	„ the group SO_3H, except in the word sulphocyanide.
sulphydro-	„ the group SH.

Tribromonitrobenzene sulphonic acid [1:2:3:4:5] means that the three bromines occupy positions 1, 2, and 3; the nitro- group the position 4, and the sulpho- group the position 5.

* Denotes that the formula to which it is affixed has not been determined by analysis. But it by no means follows that formulæ without this mark are those of analysed compounds.

All temperatures are given in degrees Centigrade unless when specially stated otherwise.

Wave-lengths are given in 10^{-7}mm.

Formulæ, when used instead of names of substances, have a qualitative meaning only.

Thomsen's notation is used in thermochemical data.

DICTIONARY OF CHEMISTRY

CHENOCHOLIC ACID $C_{27}H_{44}O_4$. Formed by boiling taurochenocholic acid, from goose-bile, with baryta-water (Heintz a. Wislicenus, *P.* 108, 547). Amorphous mass (from alcohol or ether), insol. water. Gives Pettenkofer's reaction with H_2SO_4 and sugar. Insol. cold KOHAq, but dissolves on warming, forming a solution that is ppd. by $BaCl_2$ and $CaCl_2$.—BaA'_2 (dried).

CHENOPODINE $C_6H_{13}NO_4$. This base, which occurs in white goosefoot (*Chenopodium album*) (Reinsch, *N. J. P.* 20, 268; 21, 132; 27, 193; *J. pr.* [2] 22, 188), is probably leucine (Gorup-Besanez, *B.* 7, 147).

CHICA. A red dye obtained from the leaves of *Bignonia Chica* growing in South America. The colouring-matter may be extracted by alcohol. It is insol. ether and Na_2CO_3Aq, but sol. NaOHAq. Chromic acid oxidises it to anisic acid (Erdmann, *J. pr.* 71, 198).

CHICORY. The blue blossoms of *Cichorium Intybus* contain a glucoside $C_{32}H_{34}O_{19}$ 4½aq [215°-220°], which may be extracted by dilute alcohol. It crystallises from water, in which it is slightly soluble, in needles. Aqueous alkalis and alkaline carbonates form yellow solutions. Boiling dilute acids split it up into glucose and $C_{26}H_{14}O_9$ [250°-255°], which also occurs in the blossoms. This forms needles, v. sl. sol. boiling water, coloured dark green by Fe_2Cl_6 (Nietzki, *J.* 1876, 851; *Ar. Ph.* [3] 8, 327).

CHICLE ALBAN $C_{10}H_{16}O$. [145°]. S. (alcohol of S.G. ·82) ·66 at 14°. Obtained by extracting chicle gum (Mexican rubber juice), from *Chrysophyllum glycyplacum*, with weak alcohol (Prochazka a. Endemann, *A. C. J.* 1, 50). The mother liquor deposits chicle fluavil $C_{20}H_{32}O$ (?); S. (alcohol of S.G. ·82) 2·6 at 13·5°. The residue of the gum, after extracting with alcohol, contains two terpenes and arabin.

CHIN-. Substances beginning with Chin- will be described under the alternative names which begin with Quin-. Thus Chinidine, Chinone, and Chinoline are described as Quinidine, Quinone, and Quinoline.

CHIRATIN $C_{26}H_{18}O_{15}$. Extracted by dilute alcohol from the stalks of *Ophelia chirata* (Höhn, *Ar. Ph.* [2] 139, 213). Resinous mass, decomposed by hot dilute HCl into ophelic acid and amorphous chiratogenin $C_{13}H_{24}O_3$.

CHITENIDINE $C_{19}H_{22}N_2O_4$. Formed by oxidation of quinidine with $KMnO_4$. Thin plates (containing 2aq). Sol. alkalis and hot water, sl. sol. alcohol.—$B''H_2SO_4$ 3aq: white prisms.—$B''H_2Cl_2PtCl_4$ 3aq: large orange-red needles (Forst a. Böhringer, *B.* 15, 1659).

CHITENINE $C_{19}H_{22}N_2O_4$. Prepared by oxidation of quinine with $KMnO_4$. White prisms (containing 4aq). Insol. alcohol and ether, sl. sol. water. Very weak base.—$B_2(H_2SO_4)_2$ 15aq: fine needles.—$BH_2Cl_2PtCl_4$ 3aq (Skraup, *B.* 12, 1104).

CHITIN *v.* Proteïds, *Appendix C.*

CHLORAL C_2HCl_3O *i.e.* $CCl_3.CHO$. *Tri-chloro-acetic aldehyde.* Mol. w. 147·5. [c. −75°] (Berthelot, *Bl.* [2] 29, 3). (98° cor.) (Perkin); (97·2°) (Thorpe, *C. J.* 37, 191). V.D. 5·13. S.G. $\frac{0}{5}$ 1·5292 (Perkin, *C. J.* 51, 808); $\frac{20}{4}$ 1·5121 (Brühl, *A.* 203, 11); $\frac{0}{4}$ 1·5417 (Pa.). C.E. (0°-10°) ·001123; (0°-100°) ·001295 (Laura Passavant, *C. J.* 39, 53). μ_D 1·4623. R_∞ 43·06. M.M. 6·591 at 16° (Perkin). S.V. 107·4.

Formation.—1. By the action of chlorine on aqueous aldehyde (Pinner, *B.* 4, 256; Wurtz a. Vogt, *Z.* 1871, 679).—2. From tri-chloro-acetal and H_2SO_4 at 150° (Paterno, *A.* 150, 256; *Z.* [2] 4,733).—3. By distilling starch or sugar with HCl and MnO_2 (Städeler, *A.* 61, 101).—4. By distilling tetra-chloro-ether, $CCl_3.CHCl(OEt)$, with H_2SO_4 (W. a. V.).

Preparation.—Chlorine gas is passed into absolute alcohol, which must be cooled at first, but afterwards may be heated gradually to boiling. The crystalline chloral alcoholate formed is decomposed by shaking with H_2SO_4 and the liquid chloral rectified (Liebig, *A.* 1, 189; Dumas, *A. Ch.* [2] 56, 125; Müller a. Paul, *B.* 2, 541; Thomsen, *Z.* [2] 6, 156; Roussin, *Z.* [2] 6, 96; Personne, *C. R.* 69, 1363; Paul, *Ph.* [3] 1, 621; *C. J.* 24, 134). By-products are ethylidene chloride, ethylene chloride, and chloro-ethylene chloride (115°). The chlorination is promoted by the presence of 5 p.c. Fe_2Cl_6 (Page, *D. P. J.* 252, 343. *V.* also Chloral hydrate).

Theory of the process.—Chlorine oxidises alcohol to aldehyde, this combines with alcohol forming acetal $CH_3CH(OEt)_2$, which is then converted into tri-chloro-acetal $CCl_3CH(OEt)_2$ which is saponified by the HCl formed in the previous reactions: $CCl_3.CH(OEt)_2 + HCl = CCl_3.CH(OH)(OEt) + EtCl$ (Lieben, *C. R.* 44, 1345; *B.* 3, 910). Wurtz (*C. R.* 74, 777) considers that chloro-ether is first formed, thus: $CH_3CHO + HOEt + H$[illegible] $H_2O + CH_3.CHCl(OEt)$, and this is then converted into tetra-chloro-ether $CCl_3.CHCl(OEt)$, which is converted by alcohol into tri-chloro-acetal $CCl_3CH(OEt)_2$, which is then decomposed by HCl as above.

Estimation.—By shaking with standard NaOH and determining the amount of alkali neutralised.

Properties.—A liquid with odour resembling aldehyde. It solidifies when shaken with a little water, forming so-called chloral hydrate, but it dissolves in much water. It reduces ammonia cal silver nitrate with formation of a mirror. It is not affected by distillation over quicklime or BaO as long as the oxide is covered by the liquid. It combines with NH_3. When introduced into the blood it is split up into chloroform and formic acid (Liebreich; Personne, *C. R.* 69, 979; Byasson, *C. R.* 72, 742; Arloing, *C. R.* 89, 245, 526; *cf.* Thomaszewicz, *Pf.* 9, 35). Tanret supposed that its physiological action was due to the liberation of CO in the blood (*J. Ph.* [4] 20, 355). Some of the chloral passes into the urine as urochloralic acid $C_8H_{11}Cl_3O_7$.

Reactions.—1. Split up at once by NaOH into chloroform and sodium formate, thus:

$$CCl_3.CHO + NaOH = CCl_3H + NaCHO_2.$$

Alcoholic KOH and NaOEt act similarly, forming formic ether and chloroform (Kekulé, *A.* 119, 187). 2. Zn and HCl *reduce* it to aldehyde (Personne, *A.* 157, 113; *C. R.* 71, 227). Zinc-dust and water reduce it, on heating, to CH_4, CH_2Cl_2, and CH_3Cl (Cotton, *Bl.* [2] 42, 622).—3. Fuming HNO_3 *oxidises* it to tri-chloro-acetic acid. CrO_3 or HgO gives CO and CO_2. $KMnO_4$ gives CO_2, chloroform, oxygen, and chlorine (Cotton, *Bl.* [2] 43, 420).—4. *Chlorine* in sunlight forms CCl_4, hydric chloride, and $COCl_2$ (Gautier, *Bl.* [2] 45, 86; *C. R.* 101, 1161).—5. *Bromine* forms $CCl_3CO.Br$, CCl_3Br, CO, and HBr (Oglialoro, *B.* 7, 1461).—6. PCl_5 forms $CCl_3.CCl_2H$ (Paterno, *G.* 1, 590; *Z.* [2] 5, 245).—7. PCl_3Br_2 forms CCl_3CBr_2H.—8. H_2SO_4 forms chloralide crystals (*q. v.*). Fuming H_2SO_4 forms a crystalline compound (*v. infra*).—9. KIAq forms iodine and chloroform. 10. Al_2Cl_6 forms parachloral (240°) and C_2Cl_4 (Combes, *A. Ch.* [6] 12, 298).—11. P_2S_5 forms C_2HCl_3 (88°) (Paterno a. Oglialoro, *G.* 3, 538). 12. *Aniline* reacts violently forming tri-chloro-ethylidene-di-phenyl-di-amine $CCl_3.CH(NHPh)_2$ [101°] (Wallach, *B.* 5, 251).—13. *Acetamide* combines forming $CCl_3.CH(OH)(NHAc)$ (*v.* CHLORAL-AMMONIA).—14. *Acetonitrile* forms $CCl_3CH(NHAc)_2$ (Hübner, *B.* 6, 109; *Z.* 1871, 712; Hepp, *B.* 10, 1651): needles (from HOAc).—15. Heated with syrupy *lactic acid* at 160° chloral forms tri-chloro-ethylidene mono-lactate:

$CH_3.CH{<}\substack{CO.O\\ O}{>}CH.CCl_3$ [45°] (223°) (Wallach, *A.* 193, 86). This body may also be got by dissolving chloral hydrate (1 pt.) in syrupy lactic acid, and adding H_2SO_4 (1 pt.) (M. Nencki, *J. pr.* 125, 239). In a similar way, *tri-chloro-lactic acid* heated with chloral forms chloralide (*q. v.*); *tri-bromo-lactic acid* forms tri-chloro-ethylidene tri-bromo-lactate

$CBr_3.CH{<}\substack{CO.O\\ O}{>}CH.CCl_3$ [132°-135°]; *tri-chloro-a-oxy-valeric acid* forms

$C_3H_4Cl_3.CH{<}\substack{CO.O\\ O}{>}CH.CCl_3$ [88°], (297°); *glycollic* acid forms $CH_2{<}\substack{CO.O\\ O}{>}CH.CCl_3$ [42°]; *malic acid* forms tri-chloro-ethylidene malate

$\left.\begin{array}{l}CO_2H.CH_2.CH.O\\ \qquad\quad |\\ \qquad\quad CO.O\end{array}\right>CH.CCl_3$ [140°] (Wallach, *A.* 193, 87); *tartaric acid* gives

$CCl_3.CH{<}\substack{O\\ O.CO}{>}CH.CH{<}\substack{O\\ O.CO}{>}CH.CCl_3$;

salicylic acid forms  $C_6H_4{<}\substack{CO.O\\ O}{>}CH.CCl_3$ [124°]; while *mandelic acid* produces  $C_6H_5.CH{<}\substack{CO.O\\ O}{>}CH.CCl_3$. [82°].—16. When mixed with *benzene* (1 mol.) and concentrated sulphuric acid, di-phenyl-tri-chloro-ethane $CCl_3.CH(C_6H_5)_2$ is formed (Goldschmiedt, *B.* 6, 985). Bromo- and chloro-benzene and toluene act similarly (Zeidler, *B.* 7, 1180; Fischer, *B.* 7, 1191).—17. By acting on *benzene* with chloral in the presence of aluminium chloride a liquid is obtained having the formula $C_6H_5.CCl_2.COH,HCl$ which by oxidation forms the acid $C_6H_5.CCl_2.COOH$ (Combes, *C. R.* 98, 678; *Bl.* [2] 41, 382).—18. *Zinc methide* (1 mol.) followed by water forms $CCl_3.CH(OH).CH_3$. Excess of $ZnMe_2$ followed by water forms $(CH_3)_2CH.CMe_2.OH$.—19. *Zinc ethide* followed by water forms tri-chloro-ethyl alcohol $CCl_3.CH_2.OH$.—20. *Hydroxylamine* forms chloro-glyoxim $C_2H_3ClN_2O_2$.

Combinations.—1. With *water* v. *Chloral hydrate.*

2. With *alcohols* v. *Chloral hydrate.*

3. With *hydric sulphide*: $(C_2Cl_3HO)_2H_2S$. [128°]. Formed by passing H_2S into a solution of chloral (Hagemann, *B.* 5, 154; Wyss, *B.* 7, 211; Paterno a. Oglialoro, *G.* 3, 533). Rhombohedra (from chloroform). Insol. water, sol. alcohol and ether. Decomposed by heat. With PCl_5 it gives $CCl_3.CHCl_2$. Gives with AcCl a di-acetyl derivative [78°].

4. With *phosphuretted hydrogen*: $(CCl_3CHO)_2PH_3$. [143°]. From chloral (3 g.) and PH_4I (2g.). Small prisms (from ether). Decomposed by conc. NaOH into formate, hypophosphite, and hydrogen (Girard, *A. Ch.* [6] 2, 43).

5. With *mercaptan*: $C_2Cl_3HO,HSEt$. Crystalline.

6. With *acetyl chloride*: $CCl_3CHCl(OAc)$. (c. 187°). S.G. ^{17} 1·476 (V. Meyer, *B.* 3, 445; *A.* 171, 67; *cf.* Curie a. Millet, *C. R.* 83, 745).

7. With *acetic anhydride*: $CCl_3CH(OAc)_2$. (222°). S.G. ^{11} 1·422. Oil.

8. With *ethylamine*: $CCl_3.CH(OH)NHEt$. On distillation this forms $CHCl_3$ and ethyl-formamide H.CO.NHEt.

9. With *fuming sulphuric acid*: $(C_2Cl_3HO)_5,SO_3,2H_2SO_4$. [70°]. Chloral (1 pt.) is mixed with fuming sulphuric acid (5 pts.). The product is washed with cold water and crystallised from ether (Grabowski, *B.* 6, 225, 1070). A mixture of chloral with an equal volume of fuming sulphuric acid forms large crystals of $(CCl_3.CHO)_4,H_2S_2O_7$.

10. With *alkaline bisulphites*: $C_2Cl_3HO,KHSO_3$ (Städeler, *A.* 106, 253; Rathke, *A.* 161, 154). This compound is also formed when K_2SO_3 is used, but if the solution be heated to 80° $(SO_3K)_2CH.CHO,KHSO_3$ aq crystallises out, while the mother-liquor contains $C_6H_{22}Cl_3S_7O_{31}K_7$.

11. With *hydrogen cyanide*: $CCl_3CH(OH)CN$. *Tri-chloro-lacto-nitrile.* [61°]. (c. 216°). Prepared by the action of anhydrous *prussic acid* at 120° upon chloral (Hagemann, *B.* 5, 151) or by boiling chloral with strong prussic acid (Bischoff a. Pinner, *B.* 5, 113; *A.* 179, 77). Trimetric plates (from CS_2). Saponified by HCl forming tri-chloro-lactic acid. Saponified by KOH forming potassic formate and cyanide and chloroform. With urea it forms $CCl_3CH(NH.CO.NH_2)_2$ (Pinner, *B.* 20, 2345). Acetyl derivative.—$CCl_3CH(OAc)CN$. [31°]. (208°). From acetic anhydride and the above (Pinner a. Fuchs,

B. 10, 1059). Rhombohedra. Insol. water, sol. alcohol. Conc. H_2SO_4 in the cold forms $CCl_3.CH(OAc).CO.NH_2$.

12. Another compound with *hydrogen cyanide* $(CCl_3.CHO)_3.CNH$. [123°]. From conc. solutions of chloral and of KCN (Cech, *B.* 9, 1020). Prisms (from ether or benzene). Insol. water. Alcoholic potash (or even alcohol alone) forms di-chloro-acetic ether. On distillation it splits up into chloral and chloralide (Wallach, *B.* 6, 114). Alcoholic, or dilute aqueous, solutions of KCN convert chloral into di-chloro-acetic acid (or ether).

13. With *cyanic acid*: $(C_2Cl_3HO)_2CNOH$ [c. 169°]. Formed by passing vapour of cyanic acid into chloral, boiling the product with HCl and crystallising the residue from ether. Small prisms (Bischoff, *B.* 5, 86).

14. With both *cyanic* and *prussic acids*, C_2Cl_3HO, CNH, CNOH. [80°]. Prepared by pouring a solution of CNOK upon a mixture of solutions of chloral and KCy. Needles. Decomposed by hot water. Converted by ethylamine into $CCl_2(NEtH)CHO$. [45°] (Cech, *B.* 8, 1174; 9, 1253; 10, 880).

15. With *sodium acetate*: $CCl_3CH(OAc)(ONa)$. Minute white crystals, decomposed by water and alcohol (Rebuffat, *G.* 17, 406).

16. With *carbamic ether*: $CCl_3.CH(OH).NH.CO_2Et$. [103°]. Flaky mass (from ether-alcohol), formed by adding conc. HCl to a solution of carbamic ether in chloral (Bischoff, *B.* 7, 631). Resolved into its components by hot water or by heating at 100°.

17. With *urea*: $CCl_3.CH(OH).NH.CO.NH_2$. [150°]. From chloral and a conc. aqueous solution of urea. Scales. Decomposed on melting into chloral and cyanuric acid. The compound $(CCl_3.CH(OH).NH)_2CO$ [190°] is also formed, and differs from the preceding in being nearly insol. boiling water (Jacobsen, *A.* 157, 246).

18. With *benzamidoxim*: $C_9H_9N_2Cl_3O_2$. [135°]. White powder, insol. water, v. sol. alcohol and ether. Resolved by boiling dilute H_2SO_4 into its constituents (Falck, *B.* 19, 1481).

19. With *hexamidoxim*: $C_8H_{15}N_2Cl_3O_2$. [130°]. White pearly plates. Formed by heating the components together for a long time (Jacoby, *B.* 19, 1505).

20. With *thio-benzamide*: $CCl_3.CH(OH).NH.CS.C_6H_5$. [104°]. From chloral and thio-benzamide (Spica, *G.* 16, 182). Rhomboidal prisms of alliaceous odour, sl. sol. water, sol. alcohol and ether.

Chloral-ammonia $CCl_3.CH(OH).NH_2$. [64°]. Formed by passing NH_3 into a solution of chloral in chloroform (Städeler, *A.* 106, 253; Schiff, *B.* 10, 167). Insol. cold water, decomposed by hot water into $CHCl_3$ and ammonic formate (Personne, *A.* 157 114). Boiling alcoholic KCN converts it into di-chloro-acetamide (R. Schiff a. Speciale, *G.* 9, 338). With benzoic aldehyde it gives $CCl_3.CH(OH).N:CHPh$ [130°], which crystallises from benzene in white leaflets, resolved by dilute acids into benzoic aldehyde, chloral, and NH_3 (Schiff, *G.* 9, 436).

Acetyl derivative.—$CCl_3CH(OH)NHAc$. *Chloral-acetamide.* [156°]. Formed by the action of acetyl chloride or acetic anhydride on the above, or from chloral and acetamide. Trimetric plates (from water). Insol. ether. Decomposed by heat into chloral and acetamide. Alcoholic KCN forms $C_{14}H_{18}Cl_8N_4O_5$. [120°] (S. a. S.).

Di-acetyl derivative. $CCl_3.CH(OAc)(NHAc)$. [118°]. Formed by the action of ClAc at 120° on the preceding. Decomposed by warm water into the preceding and acetic acid, the group (OAc) being unstable in presence of so much chlorine.

Dichloracetyl derivative. $CCl_3.CH(OH).NH.CO.CHCl_2$. [105°]. From chloral and di-chloro-acetamide (S. a. S.). Large prisms (from water).

Benzoyl derivative. $CCl_3.CH(OH).NHBz$. [151°]. From benzamide and chloral (Jacobsen, *A.* 157, 245) or by passing HCl into a mixture of chloral-hydrate and benzonitrile (Pinner a. Klein, *B.* 11, 10). Tables (from alcohol). Alcoholic KCN forms a compound $C_{10}H_{11}Cl_3N_4O$ [131°], which separates in small crystals from ether (S. a. S.).

Chloral hydrate $C_2H_3Cl_3O_2$ *i.e.* $CCl_3.CH(OH)_2$. *Tri-chloro-acetic ortho-aldehyde.* Mol. w. 165·5. [57°]. (97°). S.G. $\frac{50}{50}$ 1·6415 (Perkin, *C. J.* 51, 808); $\frac{60}{4}$ 1·575; S.G. (solid) 1·901. V.D. 2·8 (corresponding to a mixture of water and chloral). S. (in CS_2) 2 at 15°; 20 at 46°. R_∞ 47·94 (in a 33·2 p.c. aqueous solution) (Kanonnikoff, *J. pr.* [2] 31, 347). M.M. (fused) 7·151 at 54·6°; (in aqueous solution) 7·02 at 14°.

Formation.—By direct union of chloral with water, absorption of heat taking place (Phipson, *C. N.* 25, 257).

Preparation.—Alcohol (400g. of 97 per cent.) is poured upon crystallised ferric chloride (5g. of Fe_2Cl_6 12aq) and a large excess of chlorine is passed in. The product is distilled. The distillate contains chloral and chloral hydrate but not chloral alcoholate. After rectification the portion boiling between 94° and 97° is converted by water into chloral hydrate (525 g.) (Page, *A.* 225, 220; *cf.* Detsenyl, *C. C.* 1873, 767). Chloral hydrate may also be purified by crystallisation from CS_2 (Flückiger, *Z.* 6, 432).

Properties.—Monoclinic plates, v. sol. water and alcohol. By shaking with conc. H_2SO_4 it is at once converted into chloral. In doses of more than 5 g. it produces sleep (Liebreich, *B.* 2, 269). It is antiseptic, preventing putrefaction of proteïds. The vapour of chloral hydrate is split up by heat into chloral and water; the dissociation is complete at 100° at the ordinary pressure, and even at 61° under a pressure of 9 mm. (Wurtz, *C. R.* 89, 190; *cf.* Moitessier a. Engel, *C. R.* 86, 971; Troost, *C. R.* 84, 708; 85, 32, 400; 100, 834; *A. Ch.* [5] 13, 411; 22, 155; Friedel, *Bl.* [2] 43, 56; *C. R.* 100, 891; Naumann, *B.* 9, 822).

The molecular magnetic rotation indicates that chloral hydrate exists as such in its aqueous solution. In amyl oxide solution it begins to dissociate between 30° and 40° (Perkin, *C. J.* 51, 808). Chloral hydrate differs from chloral in not exhibiting Schiff's test for aldehydes with rosaniline and SO_2 (V. Meyer a. Caro, *B.* 13, 2343).

Detection.—Chloral hydrate may be extracted by ether from its aqueous solution (*e.g.* urine) and the following tests may then be applied: (*a*) Warming with alcoholic KOH and aniline gives (even with ·000015g.) the disgusting odour of phenyl carbamine. (*b*) Warming at 50° with conc. KOHAq and a little phenol gives a blue colour (with ·00005g.). (*c*) After boiling with potash formic acid may be detected (with ·00011g.). (*d*) Lime-water and H_2S give a pink colour (with ·00066g.) (Dragendorff a. Tiesenhausen, *C. C.* 1886, 636). The valuation of chloral hydrate may be effected by decomposing it with ammonia, KOHAq, or, better, with H_2SO_4 (Versmann, *Ph.* [3] 1, 701, 965; Wood, *Ph.* [3] 1, 7[illegible]; *cf.* Müller, *Z.* [2] 7, 66; *C. J.* 24, 444; Paul, *Ph.* [3] 1, 621; *C. J.* 24, 134).

Reactions.—1. With KCy it forms di-chloro-acetic acid.—2. Heated with *glycerin* it forms chloroform, formic acid, and allyl formate (Byasson, *C. R.* 75, 1628).—3. Boiled with *ammonic acetate* it forms chloralimide, $CCl_3.CH{:}NH$ (Pirner a. Fuchs, *B.* 10, 1068).—4. Warmed with aqueous KHS deposits sulphur, and then crystals of $C_4H_7Cl_3O_2S$ [97°] (Michael, *B.* 9, 1267; *cf.* Nicol, *C. N.* 43, 43).—5. With aqueous *ammonic sulphide* it forms a red powder $C_{18}H_{24}S_{11}N_4O_6$. This dye separates from petroleum in lustrous green crystals (E. Davy, *P. M.* [4], 68, 247; Lerch, *C. C.* 1887, 299).—6. Melted with $KClO_3$ it reacts violently with production of tri-chloro-acetic acid and decomposition products (Seubert, *B.* 18, 3336).—7. Boiled with *zinc-dust* it is decomposed with formation of chloride and oxychloride of zinc and liberation of hydrogen and CH_4 (Cotton, *Bl.* [2] 42, 622).—8. HgO decomposes chloral hydrate with formation of $COCl_2$, carbonic oxide, and CO_2.—9. $KMnO_4$ liberates chlorine, CO_2, and oxygen with formation of $CHCl_3$ (Cotton, *Bl.* [2], 43, 420).—10. Heated with ammonic sulphocyanide forms a white crystalline body $C_5H_5Cl_6N_3S$, insol. water, sol. alcohol (Nencki a. Schaffer, *J. pr.* 126, 430; Brodsky, *M.* 8, 27).—11. *Camphor* forms an unstable compound (vol. i. 670).—12. *Acetyl chloride* forms $CCl_3.CHCl(OAc)$ (Meyer a. Dulk, *B.* 4, 963).—13. With *di-methyl-aniline* and $ZnCl_2$ it gives $CCl_3.CH(OH).C_6H_4NMe_2$ (Knoeffler a. Boessneck, *B.* 20, 3193).

Acetyl derivative $CCl_3.CH(OAc)_2$. (222° uncor.). S.G. ^{11} 1·422. From chloral and Ac_2O. Liquid, insol. water, not attacked by cold KOHAq (Geuther, *A.* 106, 249).

Ethyl ether $CCl_3.CH(OH)(OEt)$.

Chloral alcoholate. Mol. w. 193·5. [56°]. (Jacobsen); [46°] (Lieben, *B.* 3, 909). (115°) (Martius a. Bartholdy, *B.* 3, 443). S.G. $^{66}_{4}$ 1·329. V.D. (air = 1): 8·49 at 200° (theory: 6·68). The vapour-pressure has been examined by Ramsay a. Young (*C. J.* 49, 686). Formed by the union of chloral with alcohol (Personne, *C. R.* 69, 1363; *cf.* Roussin, *C. R.* 69, 1144; Thomsen, *B.* 2, 597; Lieben, *B.* 3, 907; Jungfleisch, Lebaigne a. Roucher, *J. Ph.* [4] 9, 208). Its vapour is dissociated by heat. Separated from aqueous solution by $CaCl_2$. Decomposed by H_2SO_4 with liberation of chloral. With PCl_5 it gives tetra-chloro-ether, $CCl_3.CHCl.OEt$ (Henry, *C. J.* 24, 255, 696; *B.* 4, 101, 435).

Ethyl-acetyl derivative $CCl_3(OAc)(OEt)$. (198° uncor.). S.G. ^{11} 1·327. From chloral alcoholate and AcCl. Also from tetra-chloro-ether and AgOAc (Busch, *B.* 11, 447).

Methyl-ethyl ether $CCl_3(OMe)(OEt)$. (193·4°). S.G. ^{24} 1·32. From tetra-chloro-ether and MeOH (Magnanimi, *G.* 16, 330). Liquid, smelling like camphor.

Chloro-ethyl ether $CCl_3.CH(OH)OCH_2.CH_2Cl$. From chloral and glycolic chlorhydrin. Converted by PCl_5 into $CCl_3.CHCl.O.CH_2.CH_2Cl$ (Henry, *B.* 7, 763).

Methyl ether $CCl_3.CH(OH)(OMe)$. *Chloral methyl-alcoholate.* [50°]. (106°) (Jacobsen, *A.* 157, 243); (98°) (Bartholdy a. Martius, *B.* 3, 443). From chloral and methyl alcohol.

Di-methyl ether $CCl_3.CH(OMe)_2$. (183°). S.G. 1·28. From $CCl_3.CHCl.O.CH_3$ and MeOH. Liquid, smelling of camphor (Magnanimi, *G.* 16, 330).

Di-ethyl ether $CCl_3.CH(OEt)_2$. *Tri-chloro-acetal.* (197°) (B.); (200°) (W. a. V.); (205° cor.) (P. a. P.). S.G. ^{0} 1·281 (P. a. P.). S. ·5. Formed by passing chlorine into dilute (75 p.c.) alcohol; or by treating chloral alcoholate with chlorine at 80° (Byasson, *Bl.* [2] 32, 304; *C. R.* 87, 26). Formed also by treating tetra-chloro-ethyl oxide $CCl_3.CHCl.OEt$ with alcohol in sealed tubes (Wurtz a. Vogt, *C. R.* 74, 777; Paterno a. Pisati, *G.* 2, 333). Liquid, smelling like di-chloro-acetal. Miscible with alcohol and ether. By heating with water or H_2SO_4 it is resolved into chloral and alcohol. Hot alkali has no action. HNO_3 gives tri-chloro-acetic acid. A solid isomeride is described under CHLORO-ACETIC ALDEHYDE.

Allyl ether $CCl_3.CH(OH)(OC_3H_5)$. *Chloral allyl-alcoholate.* [21°]. (116°). From chloral and allyl alcohol. Needles (Oglialoro, *B.* 7, 1462).

Acetyl derivative $CCl_3.CH(OAc)(OC_3H_5)$. (106°) (Oliveri, *G.* 14, 13).

Isoamyl ether $CCl_3.CH(OH)(OC_5H_{11})$. *Chloral amyl-alcoholate.* [56°]. (146°). S.G. (liquid) ^{25} 1·234.

Cetyl ether $CCl_3.CH(OH)(C_{16}H_{33})$. *Chloral cetyl-alcoholate.* Very small needles.

Ethylene ether $CCl_3.CH(OH).OC_2H_4O.CH(OH).CCl_3$. *Chloral glycolate.* From chloral and glycol (Henry, *B.* 7, 762).

Isomeride of chloral hydrate. Chloral mixed with glacial HOAc and evaporated quickly is converted into an isomeride of chloral hydrate [80°], although the same solution when evaporated slowly deposits ordinary chloral hydrate [57°] (V. Meyer, *B.* 6, 449; *A.* 171, 74).

Meta-chloral $(C_2Cl_3HO)_n$. Formed by leaving chloral to stand with H_2SO_4. Chloral that has been freed from all traces of H_2SO_4 by distillation over BaO remains liquid for years (Byasson, *C. R.* 91, 1071). Amorphous solid, insol. water. HNO_3 oxidises it to tri-chloro-acetic acid. Alkalis form formate and chloroform. At 180° it is converted into ordinary chloral (Kolbe, *A.* 54, 183). Trimethylamine also polymerises chloral.

Parachloral $(C_2Cl_3HO)_n$. (240°). Formed, together with tetra-chloro-ethylene, by treating chloral with Al_2Cl_6 (Combes, *A. Ch.* [6] 12, 268). Liquid; oxidised by HNO_3 to tri-chloro-acetic acid.

'Para-chloralide' $(C_2Cl_3HO)_n$. (182°). S.G. ^{14} 1·577. An isomeride of chloral said to be formed by the action of chlorine on methyl alcohol (Cloez, *A.* 111, 178).

CHLORALIDE $C_5H_2Cl_6O_3$

$$i.e.\ CCl_3.CH\left\langle\begin{matrix}O.CO\\O\end{matrix}\right\rangle CH.CCl_3.$$

Tri-chloro-ethylidene tri-chloro-lactate. [115°].

(273°). V.D. 11·3 at 300° (calc. 11·2). Formed, together with metachloral, by the action of H_2SO_4 on chloral. Also by heating chloral with tri-chloro lactic acid at 150° (Wallach, *A.* 193, 1; *B.* 8, 1578).

Preparation.—Chloral hydrate (1 vol.) is heated at 90° with a mixture of conc. H_2SO_4 (1½ vols.) and fuming H_2SO_4 (1½ vols. of S.G. 1·85) in a flask with inverted condenser until crystallisation begins in the neck of the flask. The contents are shaken till cold, and then poured into water. The insoluble chloralide is washed with water and recrystallised from ether or chloroform (Otto, *A.* 239, 262; *cf.* Städeler, *A.* 61, 104; Grabowsky, *B.* 8, 1433; Kekulé, *A.* 105, 293).

Properties.—Monoclinic prisms (from ether). Insol. water, sl. sol. cold alcohol. Distils without decomposition. Boiling KOH splits it up into chloroform and formic acid. Alcohol at 150° gives chloral alcoholate and ethyl tri-chloro-lactate [67°]. Zn and HCl in alcoholic solution reduce it to aldehyde and di-chloro-acrylic acid. PCl_5 forms an oil $C_5HCl_7O_3$. S.G. $\frac{20}{4}$ 1·7436 (Anschutz a. Haslam, *A.* 239, 300).

CHLORANIL *v.* TETRA-CHLORO-QUINONE.

Vapour-pressure of liquid HCl (−73°) 1368 mm.; (−51°) 3800 mm.; (−30°) 8056 mm.; (0°) 19912 mm. (Faraday, *T.* 1845. 155). H.F. [H, Cl] = 22,000; [H, Cl, Aq] = 39,315 (*Th.* 2, 20). Critical point = 51·25° (Ansdell, *Pr.* 30, 117). S.G. liquid HCl (0°) ·908, (7·5°) ·873, (33°) ·748, (47·8°) ·619 (A.). Coefficient of compressibility (liquid HCl) for pressure from 52·8 to 208·19 atmos. at 47° = ·00166, at 33° = ·00096, at 15·85° = ·00062, at 5·7° = ·000397 (A.).

Occurrence.—In the gases of volcanoes, and in streams issuing in volcanic districts (Bunsen, *P.* 83, 197). In the gastric juice of mammals (Boedeker a. Troschel, *B. B.* 1854 486). An aqueous solution of HCl has been known for many centuries; the gas was first prepared approximately pure by Priestley in 1774. The acid was thought to be the oxide of an unknown element, *murium*, until Davy proved in 1810 that it was a compound of H and Cl.

Formation.—1. By the action of diffused sunlight on a mixture of equal volumes H and Cl. The mixture is best prepared by electrolysis of conc. HClAq, using carbon electrodes (Roscoe, *C. J.* 8, 16). Combination occurs explosively in direct sunlight, or in electric, or magnesium, light, or in the light produced by burning NO in CS_2 vapour. Combination may also be caused by heating to 150°, or by bringing the gases into contact with Pt black, or by absorbing them in charcoal. The gases do not combine in the dark at ordinary temperature. For details regarding the rate of combination by exposure to light *v.* CHEMICAL CHANGE, vol. i. p. 749. 2. By the action of Cl on H_2O in sunlight; or Cl on H_2S, HI, turpentine, and many other organic compounds.—3. By the action of H_2SO_4Aq or other acid on various metallic chlorides.—4. By the action of superheated steam on $MgCl_2$, or on $CaCl_2$ mixed with sand.

Preparation.—1. By adding to 100 parts pure NaCl, in a flask with an exit tube and safety funnel, about 150 parts pure H_2SO_4Aq, prepared by diluting the conc. acid with ⅓ to ¼ its weight of H_2O and cooling, and gently warming. The gas is passed through a little conc. HClAq, and then dried by $CaCl_2$; it is collected over Hg, or by downward displacement of air. If the materials react in the proportions $NaCl:H_2SO_4$, $NaHSO_4$ and HCl are formed at ordinary temperatures; then adding NaCl and strongly heating, $NaHSO_4$ and NaCl give Na_2SO_4 and HCl. If HClAq is to be prepared, the gas is led into cold water, the exit tube passing only a little way under the surface: the HClAq may be purified by redistillation in contact with a little Cu (to remove Cl), after standing with pure $SnCl_2$ (to remove As), (*v.* Bettendorff, *Z.* [2] 5, 492; Zettnow, *D. P. J.* 205, 247; Hager, *Fr.* 1872. 306; Oster, *Fr.* 1872. 463; Houzeau, *A. Ch.* [4] 7, 484; Reinsch, *J. pr.* 24, 244; Otto, *B.* 19, 1903).—2. By dropping conc. H_2SO_4Aq, through a tube with glass stop-cock, into a flask about one-third filled with commercial HClAq; the liquid gets warm and all the HCl except about ·32 p.c. is evolved (P. Hoffmann, *B.* 1, 272). Liquid HCl may be prepared on a small scale by placing a few pieces of NH_4Cl in the closed end of a W shaped tube, running a little conc. H_2SO_4 by means of a bent funnel tube into the second bend of the tube, closing and thickening the open end, and, after cooling, allowing the acid to flow on to the NH_4Cl, and cooling the other limb of the tube. After a little the limb containing the reacting bodies is gently warmed when liquid HCl collects in the cooled limb (Davy a. Faraday, *T.* 1823. 164).

Properties.—HCl is a colourless gas with most irritating, acrid odour; it fumes in moist air. The dry gas does not redden litmus paper. At 10° under pressure of 40 atmospheres HCl condenses to a colourless liquid (Faraday, *T.* 1845, 155). HCl is largely absorbed by water with production of much heat; [HCl,Aq] =

17,314 (*Th.* 2, 19). The solution is strongly acid; the affinity is taken by Ostwald as 100 (*v.* AFFINITY, vol. i. p. 75). When heated, conc. HClAq gives off HCl and H_2O; the temperature rises to 110° at mean barometric pressure when a liquid S.G. 1·1 and containing 79·8 p.c. H_2O and 20·2 p.c. HCl distils over unchanged. This composition corresponds with the formula $HCl.8H_2O$; but it is not probable that the liquid is a definite hydrate; the B. P. and composition of the liquid vary with the pressure. The following numbers give the B. P. of HClAq, and the composition of the liquid remaining in the retort, at various pressures (Roscoe a. Dittmar, *A.* 112, 328; *v.* also Bineau, *A. Ch.* [3] 7, 257):—

Pressure in mm.	B.P.	P.c. HCl in residual liquid
100	62°	22·8
200	76	22·1
300	84	21·7
490	97	20·9
760	110	20·2
1520	—	19·1
2280	—	18·1

If dry air is passed into conc. HClAq the liquid loses HCl; the residual liquid has a constant composition for a specified temperature. The following numbers give the composition of the HClAq remaining at $t°$ after passage of dry air until HCl ceases to come off (Roscoe a. Dittmar, *A.* 112, 328):—

$t°$	P.c. HCl.	$t°$	P.c. HCl.	$t°$	P.c. HCl.
0°	25·0	35°	23·9	70°	22·6
5	24·9	40	23·8	75	22·3
10	24·7	45	23·6	80	22·0
15	24·6	50	23·4	85	21·7
20	24·4	55	23·2	90	21·4
25	24·3	60	23·0	95	21·1
30	24·1	65	22·8	100	20·7

The following table (Roscoe a. Dittmar) shows that the liquid obtained by passing air into HClAq at a specified temperature has, in many cases, the same composition as the liquid which boils at that temperature under a certain pressure:—

Pres. in MM.	B.P.	P.c. HCl.	Temp. with air-stream.	P.c. HCl.
100	61°–62	22·8	62°	22·9
210	76 –77	22·1	77	22·2
300	84 –85	21·7	85	21·7
380	91	21·3	91	21·4
490	97	20·9	98	21·1

The S.G. and composition of HClAq are given in the following table (Ure). Temp. 15°.

1·205	39·1	41·2	130·0	121·5	115·4
1·210	40·2	42·4	132·7	125·0	119·0
1·212	41·7	42·9	134·3	126·6	120·1

Kremers (*P.* 108, 115) gives a table by which the S.G. of HClAq can be found at a temperature other than 19·5° which temperature is taken as normal. (See table on next page.)

Thus, an acid containing 25·5 p.c. HCl has S.G. = 1·101 at the normal temp. (19·5°), at 40° the S.G. will be $\frac{1\cdot101}{1\cdot00877} = 1\cdot092$, at 100° the S.G. will be $\frac{1\cdot101}{1\cdot03867} = 1\cdot06$. Thomsen, using the numbers in Ure's table, gives the S.G. of HClAq at 15° as $\text{S.G.} = \frac{100}{100-p}\left(\frac{100-1\cdot0765\,p}{100-\cdot726\,p}\right)^{\frac{3}{2}}$, where p = p.c. of HCl (*P. Jubelband*, 144).

Reactions.—1. Decomposed by *heat*, at about 1500°, into H and Cl, which combine again on cooling. If a silver tube kept cold by running water is placed inside a porcelain tube in a wind furnace, and HCl is passed through the latter tube, the free Cl combines with the Ag, and H remains (Deville, *C. R.* 60, 317).—2. Moist, but not dry, HCl is decomposed by *oxygen* in presence of *sunlight* (Richardson, *C. J.* 51, 801).—3. *Electric sparks* very slightly decompose HCl.—4. Many *metals* decompose HCl when heated in it, giving chlorides and H; *metallic oxides* form H_2O and Cl; many metallic peroxides also set free Cl.—5. HCl is *not combustible.*—6. Mixed with *air* and passed through a hot porcelain tube, or over hot pumice, H_2O and Cl are formed (*comp.* CHLORINE; *Formation*, No. 3).—7. By the action of *platinum black* on a mixture of 1 vol. HCl with $\frac{1}{2}$ vol. O water is formed (Henry, *T.* 1800. 188).—8. HCl is completely decomposed by *sodium amalgam* at the ordinary temperature. (This is applied as a lecture experiment for demonstrating the composition of HCl, by Hofmann; *v. Einleitung in die moderne Chemie* (5th ed.), 73).—9. An *aqueous solution* of HCl exposed to air and sunlight evolves a little Cl.—10. Conc. HClAq evolves only H and Cl on *electrolysis*; diluted with 9 vols. or more H_2O, O is also evolved. Riche (*C. R.* 46, 348) says that by electrolysis of HClAq, $HClO_4Aq$ is formed.—11. Conc. HClAq heated to 200° with *amorphous phosphorus* produces PH_3 and H_3PO_4Aq.—12. An *aqueous solution* of HCl is decomposed by many *metals* with formation of chlorides and evolution of H. Let this decomposition be expressed by the equation $R + 2HClAq = RCl_2Aq + H_2$; then considered thermally this is composed of the parts (1) $-[H^2, Cl^2, Aq]$, (2) $+[R, Cl^2, Aq]$. The value of (1) is about 79,000, but is less the less the quantity of water used; for very conc. solutions it is equal to about 69,000: if then the value of $[R, Cl^2, Aq]$ is greater than 79,000 we should expect the metal R to decompose dilute HClAq; if $[R, Cl^2, Aq]$ is greater than 69,000 we should expect R to decompose conc. HClAq. $[R, Cl^2, Aq]$ is greater than 79,000 when $R = K_2$, or other alkali metal, Ag_2, Ca, Ba, Sr, Mg, Cd; Zn, Mn, Fe, Co, Ni, Sn. $[R, Cl^2, Aq]$ is less than 79,000 when $R = Tl_2$, Pb, Cu, Hg, Pd, Pt, or $\frac{1}{3}$ Au_2; these metals do not decompose dilute HClAq. Now $[Pb, Cl^2, Aq] = 75,970$, which is > 69,000; Pb decomposes conc. HClAq. The following quantities of heat are produced, per 2 grams of H formed, by the action of certain metals on HClAq; these numbers afford approximate values of the relative intensities of the actions: Mg = 108,800;

Temp. of 19·5°	S.G. 1·0401 8·9 p.c. HCl	S.G. 1·0704 16·6 p.c. HCl	S.G. 1·101 25·5 p.c. HCl	S.G. 1·133 35·8 p.c. HCl	S.G. 1·1608 46·6 p.c. HCl

Al = 79,920; Mn = 49,370; Zn = 34,210; Fe = 21,320; Co = 16,190; Ni = 15,070; Sn = 2,510. (Data from Thomsen).—13. When dilute HClAq is added to a dilute solution of a *chloride* of an alkali, alkaline earth, or magnesian, metal, little or no thermal change occurs; but when a solution of chloride of Au, Pt, Pd, Hg, or Sn is used a considerable quantity of heat is produced: thus, $[Au^2Cl^6Aq, 2HClAq] = 9,060$. Several acids containing H, Cl, and Au, Pt, Hg, or Pd, have been prepared as solids; *e.g.* $H_2PtCl_6.6H_2O$, $HAuCl_4.4H_2O$ &c. There can be little doubt that solutions of $AuCl_3$, &c. in HClAq contain definite acids; the heats of formation of these acids have been calculated from experimental data by Thomsen (*Th.* 3, 536; *v.* also the various metals):

R	$[R, Cl^2, 2HClAq]$
Sn	81,000
Hg	61,780
Pd	47,920
Pt	41,830

R	$[R, Cl^4, 2HClAq]$
Sn	156,920
Pd	72,949 (?)
Pt	81,620

R	$[R, Cl^3, HClAq]$
Au	31,800

The heats of neutralisation of these acids are the same as that of H_2Cl_2Aq, viz. 2 × 13,740 (*v.* also Gold, Mercury, Palladium, Platinum, Tin).—14. HClAq dissolves many *metallic oxides*; most *peroxides* evolve Cl; *carbonates* of the alkali and alkaline earth metals, and of the heavy metals except Ag, dissolve with evolution of CO_2; most *metallic sulphides* are decomposed and H_2S produced.—15. Heated with *bromic or iodic acid*, H_2O and BrCl or ICl are formed.—16. With chloric or hypochlorous acid, and the salts of these acids, Cl is evolved (*v.* further chloric acid and chlorates, and hypochlorous acid and hypochlorites, under Chlorine, oxy-acids of, p. 15).—17. When conc. HClAq is mixed with conc. *aqueous nitric acid* a yellow liquid is formed which dissolves Au, Pt, &c. metals which are insoluble in either HClAq or HNO_3Aq. This liquid is known as *aqua regia*; its solvent action is due to the presence of Cl and NOCl; $HNO_3Aq + 3HClAq = 2H_2OAq + NOCl + Cl_2$. By the action of *aqua regia* on metals chlorides are formed; *e.g.* $2HNO_3Aq + 6HClAq + 3Cu = 3CuCl_2Aq + 2NO + 4H_2OAq$.

According to Gore (*R. M.* [4] 29, 541) liquid HCl does not act on metals, except Al which dissolves with evolution of H; it has also no action on many oxides, sulphides, and carbonates, which are decomposed by HClAq.

Combinations. — 1. HCl and NH_3 combine when mixed to form NH_4Cl; $[NH^3,HCl] = 41,900$ (*Th.* 2, 75).—2. HCl and PH_3 combine to form PH_4Cl, at 14° under pressure of 20 atmospheres, or at −30 to −35° at the ordinary pressure (Ogier, *C. R.* 89, 705).—3. HClAq forms acids with the *chlorides* of Au, Pt, Pd, and Sn (*v. Reactions*, No. 13). According to Ditte (*A. Ch.* [5] 22, 551) some metallic chlorides, *e.g.* $HgCl_2$, dissolve in HClAq to form definite compounds, *e.g.* $HgCl_2.HCl.7H_2O$; $SbCl_3.3HCl$, &c. — 4. With *water* to form $HCl.2H_2O$, prepared, as very unstable crystals decomposing quickly in air, by passing HCl into HClAq at −22°; crystals separate, and the temperature suddenly rises to −18° (Pierre a. Puchot, *C. R.* 82, 45, *v.* also Berthelot, *A. Ch.* [5] 14, 368).

Thomsen has measured the heat of dilution of $HCl.nH_2O$ with mH_2O. Assuming that when $n = 1$ the H_2O is in combination with HCl forming the hydrate $HCl.H_2O$, then the heat of dilution of $HCl.H_2O$ is a continuous hyperbolic function of the quantity of H_2O added: the equation, heat of dilution of $HCl.nH_2O$ with $mH_2O = \left(\frac{1}{n} - \frac{1}{n+m}\right)$ 11,980, gives values which agree very closely with the observed results, starting with $n = 2·62$, and varying m from 49 to 200; the constant 11,980 is found from the experimental results. The above formula gives the heat of dilution of HCl with 300 H_2O as 11,940, and the observed value was 17,316; the difference, 5376, represents the quantity of heat produced by the union of HCl with H_2O to form the hydrate $HCl.H_2O$. Thomsen's results do not indicate the formation of any hydrate except $HCl.H_2O$; it is fairly probable that the reactions of HClAq with hydroxides, metals, &c., are the reactions of the compound $HClH_2O$ ($? = H_2Cl.OH$), and not of HCl (*Th.* 3, 11–13; and 68–72) (*v.* further Chlorides).

M. M. P. M.

CHLORIC ACID *v.* Chlorine, oxy-acids of.

CHLORIDES. Binary compounds of Cl with more positive elements; *i.e.* with any element except F or O. Cl forms compounds with all elements except F; it combines directly with all except F, O, N, and C: much heat is usually produced during the combination, thus $[K^2,Cl^2] = 211,220$; $[Ca,Cl^2] = 169,820$; $[Zn,Cl^2] = 97,210$; $[Fe^2,Cl^6] = 192,080$; $[Cu,Cl^2] = 51,630$; $[Au,Cl^3] = 22,820$; $[H,Cl] = 22,000$; $[I,Cl] = 5,830$; $[S^2,Cl^2] = 14,260$; $[P,Cl^5] = 75,300$, &c. (Thomsen); Many metallic chlorides are produced by the action of Cl on the oxides *e.g.* $ZnCl_2$, $PbCl_2$, $MgCl_2$, $BaCl_2$; lower oxides of metals which form two oxides—*e.g.* FeO, Sb_2O_3—are usually partly chlorinated and partly oxidised by Cl, the higher oxide being usually eventually changed to chloride; all metallic oxides are converted into chlorides when mixed with charcoal and heated in a stream of Cl, thus $Cr_2O_3 + 3C + 6Cl = 3CO + Cr_2Cl_6$. Metallic chlorides are also formed by the action of Cl on many bromides, iodides, fluorides, and sulphides: they are usually obtained by the action of HClAq on metals, metallic oxides, hydroxides, or carbonates; in some cases *aqua regia* (*v.* Chlorhydric acid; *Reactions*, No. 17) is employed, *e.g.* to form $PtCl_4$. Non-metals, except C, N, O, and F, combine directly with Cl. Nitrogen chloride, NCl_3, is extremely explosive, it is formed by the action of Cl on various ammonium salts in solution; CCl_4, C_2Cl_4, C_2Cl_6, and C_3Cl_8, are formed indirectly from various carbon compounds; Cl_2O is formed by the action of Cl on HgO, ClO_2 by the action of H_2SO_4Aq on $KClO_3$; no compound of Cl with F is known. Most non-metallic chlorides are gaseous; they are decomposed by H_2O forming acids and HCl, *e.g.*

$$PCl_3 + 3H_2O + Aq = H_3PO_3Aq + 3HClAq;$$
$$SiCl_4 + 3H_2O + Aq = H_2SiO_3 + 4HClAq.$$

Most of the metallic chlorides are gasifiable without decomposition; some yield lower chlorides on heating, *e.g.* $CuCl_2$ gives Cu_2Cl_2 and Cl; a few are completely decomposed into Cl and metals, *e.g.* $PdCl_4$. A few chlorides are insoluble or nearly insoluble in water—the chief are AgCl, HgCl, Cu_2Cl_2, $PtCl_2$, AuCl—the others are soluble in water. Many metallic chlorides are decomposed by water, forming oxychlorides and HClAq, *e.g.* $BiCl_3$, $SbCl_3$; on evaporating $AlCl_3Aq$, $ZnCl_2Aq$, $MgCl_2Aq$, and a few other solutions of chlorides, decomposition into oxide and HCl or into oxychloride, occurs. Heated in superheated steam chlorides of alkali metals, Ba and Hg, are undecomposed; the others form oxides and HCl (Kunheim, *J.* 1861. 149). Most metallic chlorides are unchanged when heated in dry air; some, however, form oxychlorides, *e.g.* $FeCl_3$, $CuCl_2$, $BiCl_3$; very many are decomposed by heating in moist air. The chlorides of the alkali, alkaline earth, and earth, metals are not reduced by heating in H; the other metallic chlorides are reduced; some chlorides not reduced by H, *e.g.* $AlCl_3$, $MgCl_2$, are dechlorinated by heating with K or Na. Very many chlorides are reduced to metal by CO. Some chlorides of heavy metals, *e.g.* AgCl, are partially decomposed by digestion with aqueous solutions of bromides of alkali, alkaline earth, or magnesian, metals (*v.* Potilitzin, *B.* 18, 1522; also Thorpe a. Rodger, *C. J. Proc.* 1887–88, 20). Many metallic chlorides are partly decomposed when heated with an equivalent quantity of Br to 270°–300° (*v.* Potilitzin, *B.* 14, 1044; 15, 918; 16, 3051. For action of Br on AgCl in presence of H_2O, *v.* Humpidge, *B.* 17, 1838). Metallic chlorides are decomposed, with evolution of Cl, by heating with B_2O_3, SiO_2, or P_2O_5, in presence of steam. Aqueous acids decompose metallic chlorides, forming HCl, or in the cases of easily reducible acids—*e.g.* HNO_3—evolving Cl; Cl is also evolved when conc. H_2SO_4 is used in presence of peroxide of Pb, Mn, Cr, &c. Heated with K_2CrO_4 and conc. H_2SO_4, metallic chlorides form CrO_2Cl_2, which may be easily condensed to a red liquid; by the action of NH_3Aq on this liquid $(NH_4)_2CrO_4Aq$ is formed (this reaction may be applied to detect chlorides in presence of bromides).

Some metallic chlorides, especially those of Hg, Au, Pt, Pd, and Sn, combine with HCl to form acids (*v.* Chlorhydric acid; *Reactions*, No. 13); many form double salts with other metallic chlorides, especially the chlorides of the less positive, with those of the very positive, metals; *e.g.* $SnCl_2.2KCl.H_2O$, $HgCl_2.2KCl.H_2O$, $PtCl_4.2NH_4Cl$, &c. Many chlorides of the more negative metals, *e.g.* $SbCl_3$, $BiCl_3$, $SnCl_2$, &c., combine with oxides of the same metals to form oxychlorides: some metallic chlorides, *e.g.* $HgCl_2$, combine with sulphides of the same metals to form sulphochlorides. Compounds are also known of chlorides of some of the more negative metals with non-metallic chlorides, *e.g.* $SnCl_4.PCl_5$, $SnCl_4.2SCl_4$, &c. Many metallic chlorides, *e.g.* $CaCl_2$, $AlCl_3$, AgCl, $CoCl_2$, $CrCl_3$, $HgCl_2$, $PtCl_2$, combine with NH_3 to form stable compounds (*v.* Ammonium compounds; and, in more detail, the various metals, especially Chromium, Cobalt, Copper, Mercury, Platinum).

Thomsen has considered the isomorphism of the hydrated metallic chlorides (*v. Th.* 2, 430). Many chlorides produced by the action of HClAq on metals or metallic oxides contain water of crystallisation; they may be divided into the four groups: (1) $RCl_2.2H_2O$; (2) $RCl_2.4H_2O$; (3) $RCl_2.6H_2O$; (4) $RCl_2.8H_2O$; when R = an atom of a divalent, or two atoms of a monovalent, metal. The members of group (1), where R = Ba, Cu, or MnHg, crystallising in the trimetric system, are isomorphous with many anhydrous sulphates, formates, perchlorates, periodates, and permanganates, *e.g.* $BaSO_4$, $PbSO_4$, $Ba(CHO_2)_2$, $KClO_4$, KIO_4, $K_2Mn_2O_8$, &c. The members of group (2), where R = Na_2, Mn, Di, Fe, crystallising in the monoclinic system, are isomorphous with sulphates and formates containing $2H_2O$, *e.g.* with $CaSO_4.2H_2O$, $Zn(CHO_2)_22H_2O$. Group (3) comprises (*a*) monoclinic chlorides where R = Mg, Ni, Co, or Mn, these are most probably isomorphous with $Cu(CHO_2)_2.4H_2O$, $MnSO_4.4H_2O$, and $Ba(SO_3)_2.4H_2O$; and (*b*) hexagonal chlorides where R = Ca or Sr, and also the class $R^{II}R^{IV}Cl_6.6H_2O$ which includes salts derived from H_2PtCl_6 and H_2SnCl_6, these are isomorphous with many sulphites and double nitrates with $4H_2O$, *e.g.* $Sr(SO_3)_2.4H_2O$, $Ce_{\frac{1}{3}}Mg_{\frac{1}{2}}(NO_3)_2.4H_2O$, $LaNi(NO_3)_2.4H_2O$, &c. Group (4) contains only one chloride, $CoCl_2.8H_2O$; it is isomorphous with the chlorates of Co, Cu, and Ni, and with the hypophosphites of Co, Fe, Mg, Ni, and Zn, containing $6H_2O$. Each group of chlorides is isomorphous with other salts containing $2H_2O$ less than the chlorides. Thomsen concludes that the $2H_2O$ may be best regarded as forming part of the acid radicle; he would represent the four groups of chlorides as

$$(1)\ R(H_2ClO)_2;\ (2)\ R(H_2ClO)_2.2H_2O;$$

$(3)\ R(H_2ClO)_2.4H_2O$; $(4)\ R(H_2ClO)_2.6H_2O$: all being derived from the acid H_2ClOH, which possibly exists in an aqueous solution of HCl (*v.* Chlorhydric acid; *Combinations*, No. 4). Armstrong (*B. A.* 1885 Meeting; Presidential address to Section A.) suggests that the name chlorhydric acid should be given to the acid present in an aqueous solution of HCl, and that

HCl itself should always be called hydrogen chloride. M. M. P. M.

CHLORIDE OF LIME—*Bleaching powder*, *v.* HYPOCHLORITES under CHLORINE, OXY-ACIDS OF (p. 17).

CHLORIDES, ORGANIC *v.* CHLORO- COMPOUNDS.

CHLORINE. Cl. (*Dephlogisticated muriatic acid gas.*) At. w. 35·37. Mol. w. 70·74. (−33·6° at 760 mm.) (Regnault). Solidifies at about −102° (Olszewski, *M.* 5, 127). S.G. (liquid) 1·33 (Faraday, *T.* 1823, 160 a. 198). V.D. 35·8 (*v. Properties*, p. 11). S.H.p. (13°−202°) (equal mass of $H_2O = 1$) ·1241 (Regnault, *Acad.* 26, 1). S.H.v. (equal mass of $H_2O = 1$) ·0928; (equal volume of air = 1) 1·35 (Clausius, *Mechan. Wärmetheorie*, [1876] 1, 62). $\frac{\text{S.H.p.}}{\text{S.H.v.}}$ (20°−34°) 1·323 (Strecker, *W.* 13, 20; experimentally determined). Vol. absorbed by 1 vol. H_2O at 760 mm. $= 3{\cdot}0361 - {\cdot}046196t + {\cdot}0001107t^2$ (Schönfield, *A.* 95, 1). $\frac{A-1}{d}$ × At. w. = 10·6 (Gladstone, *T.* 1870. 9). Emission-spectrum; principal lines are a group of 4 about 6670, followed by 9 others and then by one with wave-length 4130 (Salet, *A. Ch.* [4] 28, 24). Absorption-spectrum marked by many irregularly distributed lines; the violet is nearly wholly absorbed (Morren, *C. R.* 68, 376; Gernez, *C. R.* 74, 660).

Chlorine was discovered by Scheele in 1774 and supposed by him to be hydrochloric acid deprived of phlogiston. Berthollet regarded it as oxygenated hydrochloric acid; chlorine and hydrochloric acid were long supposed to be oxygen compounds of an unknown element. In 1809 Gay-Lussac and Thénard, showed that chlorine behaves like an element; in 1810 Davy established the elementary character of the body and gave it the name chlorine (χλωρός = yellow-green) (Scheele, *Opusc.* 1, 247; Berthollet, *Acad.* 1785. 286; Davy, *T.* 1810; Gay-Lussac a. Thénard, *G. A.* 35, 8; *A. Ch.* 91, 96).

Occurrence.—Never free; but in combination with very many metals in various rocks; in sea-water as NaCl; chlorides occur in plant-ash and in many parts of animals.

Formation. — 1. By the action of conc. HClAq on MnO_2 ($MnO_2 + 4HClAq = MnCl_2Aq + 2H_2O + Cl_2$); or better by using 1 part MnO_2, 2 parts HClAq (S.G. 1·14), and 1 part conc. H_2SO_4 diluted with its own weight of water ($MnO_2 + 2HClAq + H_2SO_4 = MnSO_4Aq + 2H_2O + Cl_2$). —2. By the action of conc. H_2SO_4 on a mixture of NaCl and $NaNO_3$; the NO_2 produced is absorbed by conc. H_2SO_4 ($2NaCl + 2NaNO_3 + 2H_2SO_4 = 2Na_2SO_4 + 2NO_2 + 2H_2O + Cl_2$) (Dunlop, *D. P. J.* 151, 48).—3. By the action of a porous substance, *e.g.* clay, on HCl mixed with air. Deacon (*C. N.* 22, 157) soaks clay-bricks in saturated $CuSO_4Aq$, and heats them to 370°−400° in a stream of 5 vols. air and 4 vols. HCl; Cl is evolved (*v.* Deacon, *C. J.* [2] 10, 275). Probably $CuCl_2$ is formed and decomposed to Cu_2Cl_2 and Cl, and the Cu_2Cl_2 is again decomposed by the air to CuO and Cl, the CuO being changed to $CuCl_2$ by the HCl (Hengsen, *B.* 9, 1674).

Preparation. — 1. 100 grams pyrolusite (MnO_2) free from carbonates are well mixed with 130 grams NaCl, and placed in a capacious flask; a cold mixture of 125 c.c. conc. H_2SO_4 (S.G. 1·85) with 105 c.c. water is added. Cl is evolved; after a time the flask is warmed in a water bath; about 80 grams of Cl are obtainable from the above quantities. The Cl carries over with it a little HCl, and sometimes $MnCl_2$; it is passed through $CuSO_4Aq$ ($CuCl_2Aq$ and H_2SO_4 are formed) and then through water. If dry Cl is required the gas must be passed through several tubes containing $CaCl_2$ and through one or two long tubes filled with pumice soaked in boiled H_2SO_4. The gas may be collected by downward displacement, or over warm water or saturated NaClAq.—2. Crystals of $K_2Cr_2O_7$ are acted on by conc. HClAq in a capacious flask, the acid being added little by little ($14HClAq + K_2Cr_2O_7 = Cr_2Cl_6Aq + 2KClAq + 7H_2O + 3Cl_2$).—3. Chloride of lime is decomposed by HClAq ($Ca(ClO)_2 + 4HClAq = CaCl_2Aq + 2H_2O + 2Cl_2$). Kammerer (*B.* 9, 1548) describes a lecture-apparatus for the convenient preparation of Cl, based on this reaction. Dry chloride of lime, intimately mixed with burnt gypsum, is slightly moistened so that it can be rolled with difficulty into balls between the fingers; the mixture is powdered in an iron mortar and then beaten into an iron frame 10–12 mm. in height; the frame is then covered with oilcloth and very strongly compressed; the compressed plate is cut into cubes, which are preserved in a stoppered bottle. When these cubes are used in a Kipp's apparatus with HClAq of S.G. 1·124 (free from H_2SO_4) diluted with its own volume of water, a steady stream of chlorine is obtained (Winkler, *B.* 20, 184).

Liquid Chlorine is prepared (Faraday, *T.* 1823. 160 & 198) by placing crystals of $Cl.5H_2O$, thoroughly pressed between folds of paper at 0°, in the closed end of a Λ tube, closing the other end, placing the $Cl.5H_2O$ in water at 35°, and the other limb of the tube in a mixture of snow and salt (*v.* also Biewend, *J. pr.* 15, 440). Mohr (*A.* 22, 162) places a mixture of dry $KHSO_4$, NaCl, and MnO_2 in the longer limb of a Λ tube, and above this a layer of $CaCl_2$; the shorter limb is closed, and placed in a mixture of snow and salt; the mixture in the longer limb is then heated, and, when liquid Cl has collected in the other limb, is again cooled to prevent re-absorption of the Cl. The operation must be conducted in the dark, else HCl and O are produced, and the tube is liable to be broken. Liquid Cl is solidified by surrounding with liquid C_2H_4 and lowering the pressure (Olszewski, *M.* 5, 127).

Properties.—A greenish-yellow gas, becoming darker in colour when heated; very irritating odour; liquefied at 15° under pressure of 4 atmospheres (Faraday, *T.* 1823. 160 & 198); at 0° under pressure of 6 atmospheres, and at 12·5° under 8½ atmos. (Niemann). Liquid Cl is dark yellow; immiscible with water; S.G. 1·33; B.P. −33·6° at 760 mm.; non-conductor of electricity (Regnault). Very poisonous; even when mixed with much air it attacks the mucous membranes and causes irritation and even blood-spitting. When working with Cl, the nose and mouth should be protected by a charcoal respirator, or by a cloth dipped in alcohol. Absorbed by porous substances, *e.g.* charcoal, with production of heat (*v.* Melsens, *C. R.* 76, 92); not combustible in O, but burns in H producing HCl. Dissolves in water with production of heat, $[Cl^2,Aq] = 2600$ (*Th.* 2, 400). Schönfield gives these data (*A.* 93, 26; 95, 8):—

1 vol. water absorbs x vols. Cl at 760 mm.

t°	*x*	*t°*	*x*	*t°*	*x*

Solubility is greatest at 10°; chlorine-water is therefore best prepared by leading Cl into H_2O kept at about 10° and repeatedly shaking. Solution of Cl in H_2O has smell of gaseous Cl; it freezes at 0°, giving Cl hydrate and ice (*v. Combinations*, No. 3); loses all Cl on boiling (on loss of Cl from Cl-water at 100° in closed vessels, *v.* Pickering, *C. J.* 37, 139); decomposes quickly in direct sunlight into HCl and O. The presence of HCl in Cl-water is detected by shaking with Hg until the smell of Cl is removed, filtering, and testing filtrate with blue litmus and with $AgNO_3Aq$.

The atomic weight of Cl has been determined (1) by analyses, and determinations of V.D., of many gaseous compounds, *e.g.* ClH, ClTl, Cl_2Zn, Cl_3Bi, Cl_4C, Cl_5Ta, Cl_6W, &c.; (2) by comparison of chlorides, &c., with isomorphous bromides, iodides, &c.; (3) by conversion of Ag into AgCl by Berzelius (*P.* 8, 17); by conversion of $NaClO_3$ and $KClO_3$ into NaCl and KCl by Penny (*T.* 129, 25); by conversion of $KClO_3$ to KCl, and $KClO_4$ to KCl, by Marignac (*A.* 44, 18); by conversion of $KClO_3$ to KCl by heat, and by decomposition of $KClO_3$ by HCl, by Stas (*Rech.* 118); by heating Ag in Cl, by ppg. Ag solution by gaseous HCl, also by HClAq, also by NH_4ClAq, by Stas (*Rech.* 38, 42, 44); by reducing $AgClO_3$ by SO_2Aq by Stas (*Nouv. R.* 208).

The atom of Cl is monovalent in gaseous molecules. Cl acts as a very negative, acid-forming, element; it appears to be positive to O, and probably to F. Combines with all elements except F, directly with all except N, O, C, and F, with many elements combination occurs at ordinary temperatures with production of much heat (*v.* CHLORIDES). Replacement of H in carbon compounds by Cl is usually accompanied by production, or increase, of acidic character, *e.g.* relative affinity of $CH_2Cl.CO_2H$ is greater than that of $CH_3.CO_2H$ (*v.* AFFINITY, vol. i. p. 88). Heats of formation, in solution, of metallic chlorides are greater than those of corresponding bromides or iodides; bromides are wholly or partially decomposed, iodides are easily decomposed, by Cl. At least two oxides of Cl are known as gases; one oxy-acid, $HClO_4$, has been obtained in separate and definite form (*v.* CHLORIDES; HALOGEN ELEMENTS; and HALOGEN ELEMENTS, BINARY COMPOUNDS OF).

The S.G. of Cl gas at 200° was found by Ludwig to be 2·45 (air = 1) (*B.* 1, 232). Many determinations have been made by V. Meyer and his pupils, using Cl prepared before and also during the experiments; the general result is that the S.G. of Cl is very slightly, if at all, less at high temperatures, 1000°–1400°, than at a red heat (*v.* Langer a. Meyer, *B.* 15, 2769; also Crafts, *B.* 16, 457); but that the S.G. of Cl formed in the apparatus by heating $PtCl_2$ at 1200°, is 2·05 (air = 1) in place of 2·45 calculated for Cl_2 (*v.* V. Meyer, *B.* 13, 721). The determinations of Jahn (*B.* 15, 1242) show that Cl does not attain the S.G. calculated for Cl_2 until it is heated to about 240° above its B.P.; the differences between the observed and calculated numbers are however very small, much less than the differences in the case of Br (*q. v.*) (*v.* HALOGEN ELEMENTS).

Reactions.—1. Cl dissolves in *water* with production of heat $[Cl^2,Aq] = 2,600$ (*Th.* 2, 400); the solution decomposes, rapidly in direct sunlight, with formation of HCl and O; according to Popper (*A.* 227, 161) $HClO_3$ is also formed. Chlorine water therefore acts as an oxidiser, *e.g.* in bleaching (Poussaint, *A.* 137, 114). The thermal value is, $2[H,Cl,Aq] - [H^2,O] = 10,270$ (Thomsen).—2. Cl decomposes *steam* rapidly when a mixture of the two is passed through a red-hot tube.—3. Aqueous solutions of *potash* (or *soda*) absorb Cl, yielding KCl and KClO in cold, and KCl and $KClO_3$ in hot, solution: $Ca(OH)_2$ absorbs Cl forming CaOCl.Cl.—4. Aqueous *ammonia* yields NH_4Cl and N; if Cl is in excess chloride of N is formed.—5. The more *basic metallic oxides* are decomposed by Cl, when dissolved or suspended in water, with formation of metallic chloride and peroxide, or metallic chloride and an oxygen compound of Cl (*v.* CHLORINE, OXIDES OF). Many metallic oxides when heated in Cl give chlorides and O; in some cases, *e.g.* Al_2O_3, B_2O_3, O is removed only when Cl is passed over a hot mixture of the oxide with carbon.—6. All *compounds of hydrogen*, except HF, are decomposed by Cl with formation of HCl; many at ordinary temperatures; *e.g.* H_3P, H_3As, H_2S, HI.—7. All *metallic bromides, iodides, and sulphides* are decomposed either at ordinary or higher temperatures.—8. *Carbon compounds containing hydrogen* are usually easily decomposed by Cl, with formation of HCl, and frequently with separation of C; turpentine *e.g.* burns in Cl with a deposit of soot. Some vegetable colours are bleached by Cl by direct removal of H; in most cases, however, the action requires the presence of H_2O and is due to the O evolved in contact with the colouring matter. (For the reactions of Cl with Ag salts *v.* Krutwig, *B.* 14, 304.)—9. An aqueous solution of *sodium thiosulphate* is decomposed by Cl; the chief reactions are (1)

$$Na_2S_2O_3Aq + 5H_2O + 8Cl$$
$$= Na_2SO_4Aq + 8HClAq + H_2SO_4Aq;$$
$$(2)\ Na_2S_2O_3Aq + 2Cl + H_2O$$

$= Na_2SO_4Aq + 2HClAq + S$; (3) $2Na_2S_2O_3Aq + Cl_2 = Na_2S_4O_6Aq + 2NaClAq$. On dilution H_2S is evolved; probably, $2Na_2S_2O_3Aq$

$$= Na_2S_3O_6Aq + Na_2SAq;\ \text{and then}$$
$$Na_2SAq + 2HClAq\ \text{(formed as in (1))}$$

$= 2NaClAq + H_2S$ (*v.* Lunge, *B.* 12, 404).—10. Many *salts* are decomposed by Cl with formation of aqueous solutions of HClO: *e.g.*

$$Na_2CO_3Aq + H_2O + 2Cl_2 = 2NaClAq + 2HOClAq + CO_2;$$

$$CaCO_3 \text{ (suspended in } H_2O) + H_2O + 2Cl_2 = CaCl_2Aq + CO_2 + 2HOClAq$$

: (*v.* Chlorine, oxy-acids of).—11. *Iodine* suspended in water is converted into HIO_3: $I_2Aq + 5Cl_2 + 6H_2O = 2HIO_3Aq + 10HClAq$.

Combinations.—1. Directly with all *elements* except O, N, C, and F; indirectly also with O, N, and C. In most cases much heat is produced (*v.* Chlorides). Dry Cl has no action on dry Na (Wanklyn, *C. N.* 20, 271); K, Na, and Sb, do not combine with liquid Cl at −80°; P and As on the other hand combine readily (Donny a. Mareska, *A.* 56, 160). The combination of Cl and H takes place slowly in the dark, but very rapidly and explosively in direct sunlight, in electric light, in Mg light, or in the light produced by burning CS_2 in NO; [H, Cl] = 22,000 (Thomsen). For more details regarding the combination of Cl and H *v.* Chlorhydric Acid, p. 5; also Chemical change, vol. i. p. 749.—2. Cl condensed in charcoal combines, without the aid of heat or light, with *sulphur dioxide* to form SO_2Cl_2 (Melsens, *C. R.* 76, 92).—3. Cl combines with *water*: when a saturated aqueous solution is cooled to 0°, or when Cl is led into H_2O kept nearly at 0°, crystals of $Cl.5H_2O$ separate out (Faraday, *Q. J. S.* 15, 71). This hydrate is best prepared by passing Cl into a little water in a flask surrounded by ice, till the water is changed to a thick yellowish magma; and then pressing strongly between thick layers of paper kept at 0°. $Cl.5H_2O$ at −50° forms white trimetric octahedra, which may be sublimed (? with partial decomposition) in a closed vessel filled with Cl, the upper part being kept below 0°. $Cl.5H_2O$ decomposes at ordinary temperatures and pressures with evolution of Cl and formation of Cl water; in a closed tube it separates into Cl and H_2O at about 35°; on cooling to 15° or so the $Cl.5H_2O$ is re-formed (*v.* p. 10, *Liquid chlorine*) (compare Wöhler, *A.* 85, 374).

Detection and Estimation.—Chlorine decomposes KIAq giving KClAq and IAq, the I is detected by the blue colour it produces with starch paste. Soluble chlorides ppt. Ag as white AgCl from $AgNO_3Aq$. Solid chlorides when heated with $K_2Cr_2O_7$ and conc. H_2SO_4 produce gaseous CrO_2Cl_2 which is easily condensed to a reddish-brown liquid; bromides and iodides under similar conditions give Br and I respectively.

Chlorine in dilute aqueous solutions may be estimated volumetrically (1) by determining the mass of I (by means of standardised $Na_2S_2O_3Aq$) set free from KIAq by the Cl, or (2) by gently warming in a closed vessel with excess of $Na_2S_2O_3Aq$—whereby part of the $Na_2S_2O_3$ is changed to $NaHSO_4$—decomposing the remaining $Na_2S_2O_3$ by boiling with HClAq, and estimating the sulphate produced by the usual methods. Chlorides, in solution, may be estimated (1) by ppg. as AgCl, washing, drying, slightly fusing, and weighing; or (2) volumetrically by means of standardised $AgNO_3Aq$, in presence of a very little K_2CrO_4Aq; the $AgNO_3Aq$ is added until the whole of the chlorine is ppd. as AgCl, the completion of the reaction being determined by noticing the production of red Ag_2CrO_4: the chloride ought to be present in the liquid as alkali or alkaline-earth chloride; the liquid must be neutral to litmus. The reaction of chlorides with $K_2Cr_2O_7$ and conc. H_2SO_4 may also be applied to the estimation of Cl in presence of I and Br (*v.* Dechan, *C. J.* [2] 49, 682).

M. M. P. M.

CHLORINE, BROMIDE OF: better called Bromine chloride; *v.* Bromine.

CHLORINE, CYANIDES OF: better called Cyanogen chlorides; *v.* Cyanogen.

CHLORINE, HYDRATE OF. $Cl.5H_2O$. Obtained by passing Cl into H_2O at 0°; *v.* Chlorine; *Combinations*, No. 3.

CHLORINE, IODIDES OF: ICl and ICl_3: better called Iodine chlorides; *v.* Iodine.

CHLORINE, OXIDES OF. Chlorine and oxygen do not combine directly. Two oxides of Cl, Cl_2O and ClO_2, certainly exist; a third is usually described as Cl_2O_3, but it is probably a mixture of ClO_2 and Cl (*v.* Chlorine trioxide). They are all unstable bodies, easily decomposing into their elements. Cl_2O is the anhydride of HClO, but this acid is known only in dilute aqueous solutions. The anhydride Cl_2O cannot be obtained from solutions of the acid; Cl_2O is prepared by the action of Cl on dry HgO. The supposed Cl_2O_3 is said to be obtained by reducing $HClO_3Aq$, generally by As_4O_6. ClO_2 is not an anhydride of a definite acid; it is obtained by the action of H_2SO_4Aq on $KClO_3$; on addition of H_2O, or KOHAq, it forms $HClO_2Aq$ and $HClO_3Aq$, or $KClO_2Aq$ and $KClO_3Aq$. The hypothetical anhydrides of $HClO_3$ and $HClO_4$, viz. Cl_2O_5 and Cl_2O_7, are unknown. The heat of formation of Cl_2O is negative; $[Cl^2,O] = -17,900$ (Thomsen). The heat of formation of the only known oxide of I, viz. I_2O_5, has a large positive value $[I^2,O^5] = 45,000$ (Thomsen).

Berthelot discovered $KClO_3$ in 1786; it was long known as *oxidised potassium chloride*. Other compounds containing Cl and O were prepared and examined by Chevenix (1802), Stadion and Davy (1815), and by Balard (1834). Millon in 1843 added much to the knowledge of the oxy-compounds of Cl. In more recent times Carius, Brandau, and Pebal have examined these compounds. The body called by Davy *euchlorine*, obtained by the action of HClAq on $KClO_3$, and supposed by him to be an oxide of Cl, has been proved to be a mixture of ClO_2 with Cl. Millon's compounds Cl_6O_{13} and Cl_6O_{17} have also been shown to be mixtures (H. Davy, *T.* 1815, 214; Gay-Lussac, *A. Ch.* 8, 408; Soubeiran, *A. Ch.* 48, 113; J. Davy, *N. Ed. P. J.* 17, 49; Millon, *A. Ch.* [3] 7, 298; Pebal, *A.* 177, 1).

I. Chlorine monoxide. Cl_2O. (*Hypochlorous anhydride.*) Mol. w. 86·7. (5° at 7[illegible]8 mm.) (Garzarolli-Thurnlackh, *A.* 230, 273). V.D. 43·5 at 10°. $[Cl^2,O] = -17,930$ (*Th.* 2, 399). S.G. 2·977 (air = 1). Absorption-spectrum shows bands in blue and violet (Gernez, *C. R.* 74, 803). S. (0°) about 200.

Preparation.—Precipitated HgO is heated to about 300° for some time, and cooled (Pelouze, *A.* 46, 195); it is placed in a long tube surrounded by water; well washed and thoroughly dried Cl is passed through the tube. The reaction is $HgO + 2Cl_2 = HgCl_2 + Cl_2O$; the Cl_2O is passed into dry flasks; as each is filled it is closed with a glass stopper which is then covered with paraffin. If liquid Cl_2O is required the tube containing HgO is connected with a Y tube, the upper part of which is cooled to at least −20°. Ladenburg (*B.* 17, 157) recommends cooling by alcohol, the temperature of which is reduced to −40° by a small ammonia-freezing machine—dry test tubes surrounded by ice and salt are placed under the Y tube, and a few drops of Cl_2O are collected in each tube. In this way the principal reactions of liquid Cl_2O may be demonstrated without danger (*v.* Ladenburg, *l.c.*). If crystalline HgO is used, no action occurs between it and Cl; if ordinary ppd. HgO is employed the action is too rapid, much heat is evolved, and no Cl_2O, but only O, is obtained.

Properties.—Reddish-yellow gas, with very irritating odour: condenses at about −20° to a blood-red liquid which boils at about −17° (Pelouze, *A. Ch.* [3] 7, 176). Both gas and liquid are very easily decomposed, sometimes with violent explosion, into Cl and O; pouring the liquid from one glass vessel to another, or contact with a scratch on the glass, may suffice to bring about an explosion. Rise of temperature, or the action of electric sparks, causes the gas to explode, with production of Cl and O (Balard, *A. Ch.* 57, 225; Gay-Lussac, *C. R.* 14, 927). The gas is said to decompose in sunlight without explosion into Cl and O, the volumes of these gases being as 2:1.

Reactions and Combinations.—1. Powdered *metals* form chlorides and oxides, or oxychlorides, frequently with explosion.—2. Many *metallic oxides* react with the gas to form chlorides and higher oxides; Ag_2O gives AgCl and O.—3. *Phosphorus*, *Sulphur*, and *Selenion*, form chlorides and oxides, with explosion.—4. *Hydrogen*, in sunlight, decomposes the gas explosively, producing HCl and H_2O.—5. Freshly heated *carbon*, cooled under Hg, detonates in Cl_2O; Cl, O, and a little CO_2 are formed.—6. *Hydrochloric acid gas* forms H_2O and Cl.—7. *Acetic anhydride*, $(C_2H_3O)_2O$, absorbs the gas forming the very unstable compound $C_2H_3O.OCl$ (Schützenberger, *C. R.* 53, 538).—8. The liquid Cl_2O sinks in *water*, and then slowly dissolves forming HClOAq (*q. v.*). Water at 0° absorbs more than 200 times its volume of gaseous Cl_2O: the solution contains HClO.

Method of Analysis. The gas was slowly passed through a narrow glass tube with three bulbs blown on it, the part of the tube before the first bulb being heated; by this means the gas was decomposed, and the three bulbs were filled with the products of this decomposition, viz., Cl and O. The bulbs were sealed by the blowpipe, and each was then opened under KOHAq; the Cl was thus absorbed while the O remained. The volume of KOHAq was measured; the bulbs were filled with KOHAq and the total volume was determined. The result was that 2 vols. Cl were found in each bulb with 1 vol. O. The weights of Cl and O formed were calculated, and the weight of the volume of the undecomposed gas which the bulb would contain when full was calculated from the observed S.G. of the gas. It was thus found that 2 vols. of the gas are decomposed by heat into 2 vols. Cl and 1 vol. O. This calculation assumes that the gas entering the small bulb contains no free Cl or O (Regnault).

II. CHLORINE PEROXIDE. ClO_2. (*Chlorine dioxide* or *tetroxide.*) Mol. w. 67·29. V.D. 38·5, 34·5 at 10·7° and 718 mm. (Pebal a. Schacherl, *A.* 213, 113). S.G. 2·315 (air = 1).

Preparation.—1. About 100 grams pure conc. H_2SO_4 is placed in a platinum dish surrounded by snow and salt; from 15 to 20 grams dry finely powdered $KClO_3$ is added little by little, with stirring with a glass rod after each addition. When so much $KClO_3$ has been added that the contents of the dish form a thick oily liquid, this is carefully poured through a funnel into a glass flask, with the neck drawn out, of a size such that it is not more than one-third filled with the liquid. The greatest care must be taken to keep the neck of the flask perfectly free from the oily liquid. The flask is kept cold; a piece of glass tubing of the same diameter as the end of the drawn-out neck of the flask is pressed closely against the end of this neck, and the joint is made tight by caoutchouc. The flask is then placed in a water bath and very slowly heated to 20°, and after some time to 30°–40°; the gas is collected, by downward displacement, in small dry flasks, or it may be liquefied by passing into small tubes surrounded by snow and salt. The whole operation is best conducted by gas-light (Millon, *J. pr.* 29, 401; Cohn, *J. pr.* 83, 54). If the liquid is prepared each tube should not contain more than 1 or 2 drops; the liquid is frightfully explosive. The gas prepared as above always contains a little Cl and O.—2. According to Jacquelain (*A. Ch.* 30, 339) fairly pure ClO_2 may be obtained by the action of a mixture of equal volumes of conc. H_2SO_4 and water on pure $KClO_3$, in a flask with a long neck, placed in water at 70° so that half the neck is immersed.—3. If a very intimate mixture of 3 pts. finely powdered $KClO_3$ with 13 pts. finely powdered crystallised oxalic acid is warmed in an oil bath to 70° a mixture of ClO_2 and CO_2 is evolved regularly and without danger; five-sixths of the Cl of the $KClO_3$ forms ClO_2 and one-sixth remains as KCl (Calvert a. Davies, *C. J.* 11, 193; *v.* also Schacherl, *A.* 206, 75).

Properties.—Yellowish-green gas, condensing (by snow and salt) to a red-brown liquid, and solidifying at about −59° (ether and solid CO_2 *in vacuo*) to hard, brittle crystals, resembling $K_2Cr_2O_7$ in appearance (Faraday, *T.* 1845. 155). Both gas and liquid are frightfully explosive; explosions often occur without any assignable cause. S.G. of liquid ClO_2 about 1·5. B.P. about 9° (Pebal, *A.* 177, 1). In a vessel wholly made of glass, liquid ClO_2 boils at 9·9° under pressure of 730·9 mm. without explosion (Schacherl, *A.* 204, 68). The gas has an irritating odour, resembling that of NO_2; it does not affect litmus paper; it is unchanged in the dark, but decomposes, usually explosively, in sunlight.

Reactions and Combinations.*—1. *Easily oxi-

dised bodies, *e.g.* P, or S, burn in ClO_2, usually with explosion.—2. *Mercury* absorbs the gas and decomposes it with detonation.—3. *Hydrogen* (8 vols. H + 3 vols. ClO_2) decomposes ClO_2 explosively in presence of spongy Pt, or of electric sparks, forming H_2O and HCl (Blundell, *P.* 2, 216; Stadion, *G. A.* 52, 197 a. 339).—4. According to Kämmerer (*P.* 138, 404) *bromine* and *iodine* do not react with gaseous ClO_2.—5. Many *organic compounds* cause explosion of ClO_2 at ordinary temperatures. — 6. Liquid ClO_2 explodes when a piece of *potash* is placed in it; if water is present, a mixture of equal equivalents of $KClO_3$ and $KClO_4$ is formed, much heat being produced.—7. Liquid ClO_2 sinks in *water*; on shaking, much gas is given off, an explosion usually takes place, and the water contains $HClO_2$ and $HClO_3$. If the water is kept at 0° yellow crystals are formed which cannot be melted without evolution of considerable quantities of gas (Millon, *A. Ch.* [3] 7, 298). Water at 4° absorbs about 20 times its own volume of gaseous ClO_2, with formation of $HClO_2Aq$ and $HClO_3Aq$ (Millon, *l.c.*); this solution decomposes in sunlight, giving off Cl and O, and after a time only $HClO_3$ remains in solution.—8. Conc. *sulphuric acid* at −18° absorbs about 20 times its own volume of gaseous ClO_2, becoming yellow in colour; on removing the acid from the freezing mixture the colour changes to reddish; at 10°-15° ClO_2, Cl_2O_3 (?), and a mixture of Cl and O in the proportion of 2 vols. to 3 vols., are evolved; when gas ceases to come off, the residue contains $HClO_4$ (Stadion, *G. A.* 52, 197 a. 339; Millon, *A. Ch.* [3] 7, 298).

Method of Analysis.—(Pebal, *A.* 177, 1; 213, 112). The gas was prepared by gently warming H_2SO_4Aq (1 vol. conc. acid to 2 vols. water) with a mixture of oxalic acid and potassium chlorate; it was washed by passing through a little water, dried by $CaCl_2$, and liquefied in a small glass bulb with two glass necks surrounded by $CaCl_2$ and snow. When about 3 c.c. of the liquid were obtained, the evolution of gas was stopped; one neck of the glass bulb was closed, and the other was connected with a glass tube, furnished with glass stop-cocks, placed in water. The freezing mixture was removed, and gaseous ClO_2 was allowed to pass slowly through the glass tube till all air was removed; the stop-cocks of the tube were then closed, and the temperature of the water and the reading of the barometer were determined. The glass tube full of ClO_2 was surrounded by fine wire gauze (in case an explosion should occur), and the water was gently warmed until decomposition of the gas occurred; the temperature of the water was then allowed to come back to the first reading. The mixed gases, or a portion of them, were then transferred to a similar graduated glass tube, filled with saturated NaClAq containing a little ClAq and placed in a cylinder full of the same solution; this solution absorbs hardly any Cl from a mixture of Cl and O. The volume of Cl in the known volume of the mixed gases was determined by absorption by KIAq. The following results were obtained:

(1) Volume-expansion on decomposition $23{\cdot}9:36{\cdot}44 = 2:3{\cdot}05$;

(2) Ratio of Cl-volume to O-volume $11{\cdot}1:23{\cdot}2 = 1:2{\cdot}09$;

(3) Ratio of O-volume to expansion $24{\cdot}65:12{\cdot}54 = 1{\cdot}96:1$;

that is, 2 vols. chlorine peroxide yields 2 vols. O and 1 vol. Cl. Then from the weights of O and Cl obtained, and the weight of chlorine peroxide used (calculated from the observed S.G. of the three gases) the formula ClO_2 is deduced. It is possible that the gas at low temperatures, or the liquid, may have the composition Cl_2O_4. ClO_2 may also be analysed by allowing the liquid to act on $FeSO_4Aq$ and determining the Fe_23SO_4 and the HCl produced;

$$10FeSO_4Aq + 5H_2SO_4Aq + 2ClO_2$$
$$= 5Fe_23SO_4Aq + 2HClAq + 4H_2O$$ (*v.* Garzarolli-Thurnlackh, *A.* 209, 205).

III. CHLORINE TRIOXIDE. Cl_2O_3. (*Chlorous anhydride.*) The existence of this body is very doubtful. The results obtained by Millon, Carius, Schiel, &c. differed considerably: thus Millon could not liquefy the gas he obtained; Schiel and others obtained a dark reddish-brown liquid by passing the gas into a tube in snow and salt. Brandau determined the S.G. of the gas to be 4·07 at 9°, 4·02 at 13°, and 3·17 at 16°; Millon gave the S.G. as 2·65 and Schiel as 2·6 − 2·73. (The calculated S.G. of Cl_2O_3 is 4·109, air = 1.) The gas was analysed by Millon by passing it over hot Cu and determining the $CuCl_2$ formed; Brandau dissolved in water and titrated with KIAq, he also reduced by HNO_2Aq and estimated the Cl. The results cannot be regarded as satisfactory. Garzarolli-Thurnlackh (*B.* 14, 28; more fully, *A.* 209, 184) in 1881 determined the relation between the expansion of the gas on decomposing it by heat and the volume of O thus obtained; he employed Pebal's method for analysis of ClO_2 (*q. v.*); the gas examined was prepared by the action of (1) $KClO_3$ and HNO_3Aq on As_4O_6 (Millon's method), (2) $KClO_3$ and H_2SO_4Aq on C_6H_6 (Carius's method modified by Brandau), (3) $KClO_3$ and HNO_3Aq on sugar (Schiel's method). In every case the volume of O obtained was almost exactly double the total expansion of the gas; but if the gas were Cl_2O_3 the volume of O must be equal to the total expansion, and this result would hold good if free Cl were mixed with the Cl_2O_3. Garzarolli-Thurnlackh concludes that the gas supposed to be Cl_2O_3 by Millon and Brandau was really a mixture of ClO_2, with varying quantities of Cl, a little O, and CO_2.

Preparation of compound said to be Cl_2O_3.—1. Millon (*A. Ch.* [3] 7, 298) used 15 pts. finely-powdered As_4O_6 and 20 pts. powdered $KClO_3$ made into a thin cream with water; to this he added 60 pts. pure HNO_3Aq (free from HCl and H_2SO_4) S.G. 1·33, diluted with 20 pts. H_2O; the mixture was placed in a flask of a size such that the liquid partly filled the neck, an exit tube was attached, and the contents gradually warmed in a water-bath to about 25°. The gas may be dried by $CaCl_2$; it is collected in dry flasks by downward displacement. The flask should be covered with a thick cloth in case of explosion. Slight explosions sometimes occur, but if the process is conducted carefully it is unattended with danger.—2. Schiel (*A.* 109, 319) used a mixture of 2 pts. $KClO_3$, ·6 to ·8 pts. cane sugar, and 8 pts. HNO_3Aq, S.G. 1·3 diluted with 3-4 pts. H_2O; the gas contained CO_2.—3. Carius (*A.* 140, 317; *v.* also Brandau, *A.* 151, 63) dissolved 10 pts. C_6H_6 in 100 pts. conc. H_2SO_4, diluted with 100 pts. H_2O, after cooling added 12 pts. powdered $KClO_3$, and heated to about 50° on a water-bath. The exit tube of the flask was connected with a series of small bulbs containing water; from these the gas passed into a tube kept at $-18°$; the liquefied oxide was separated from crystals of hydrated chloric acid (*q. v.*). About 5-7 c.c. liquid was obtained from 54 grams $KClO_3$; the liquid contained a little water and traces of ClO_2 and $HClO_3$.

Properties of the supposed compound.—The properties said to belong to Cl_2O_3 resemble those which characterise ClO_2; the former is however less explosive. It is described as a greenish-yellow gas, condensing to a dark red-brown liquid; S.G. about 1·5; the liquid volatilises at about 0°, the latter portions boiling at 8°-9°. The gas is decomposed into Cl and O at about 57° with slight explosion. In contact with most non-metals, and with Te and As detonation occurs. Pb, Cu, Sn, Sb, Ag, Zn, and Fe are unchanged in the gas; Hg absorbs it. One volume H_2O absorbs $8\frac{1}{2}$ vols. of the gas at 8°; the solution contains $HClO_2$, and after a time also $HClO_3$. Brandau says that if the water is at 0°, a solid hydrate of $HClO_2$ containing from 50 to 67·5 p.c. H_2O is produced.

CHLORINE, OXY-ACIDS OF.—Four compounds are known, $HClO$, $HClO_2$, $HClO_3$, and $HClO_4$. The anhydride of $HClO$, viz. Cl_2O, is known; the anhydride of $HClO_2$, viz. Cl_2O_3, is generally stated to be known, but the evidence is not conclusive (*v.* CHLORINE TRIOXIDE). Of the acids, only $HClO_4$ has been obtained in definite form apart from water. Aqueous solutions of $HClO$ and $HClO_2$ are easily decomposed on heating, giving $HClO_3Aq$ and $HClAq$; the most conc. solution of $HClO_3Aq$ obtained contains the acid and water in the ratio $HClO_3:4\frac{1}{2}H_2O$, this solution decomposes on heating yielding $HClO_4Aq$, Cl, and O; $HClO_4Aq$ is stable, it may be concentrated by distillation until crystals of $HClO_4.H_2O$ are obtained; by carefully heating these crystals the acid $HClO_4$ is formed, this acid is very easily decomposed with explosion. The following thermal data are given by Thomsen (*Th.* 2, 400):—

$$[H,Cl,Aq] = 39,315$$

$$\text{Diff.} = -9,385$$

$$[H,Cl,O,Aq] = 29,930$$

$$\text{Diff.} = -5,990$$

$$[H,Cl,O^3,Aq] = 23,940$$

These numbers would lead us to expect that neither $HClOAq$ nor $HClO_3Aq$ would be produced by the direct addition of O to $HClAq$; nor should we expect to form $KClO_3Aq$ by adding O to $KClAq$, for $[KClAq,O^3] = -15,370$ (Thomsen); the production of $HClOAq$ by the direct combination of Cl and O in presence of H_2O is also improbable, considering that $[Cl^2,O,Aq] = -8,490$ (Thomsen). Cl and O do not unite directly, but if a moderately basic oxide, *e.g.* HgO or ZnO, is acted on by Cl and H_2O, $HClOAq$ is produced; if a strongly basic oxide, *e.g.* K_2O or Na_2O, is used, a salt of $HClO$ is formed in solution. Odling (*Ph.* [2] 1, 469) says that $HClOAq$ is formed when a current of air laden with HCl is passed into a warm solution of $K_2Mn_2O_8$ containing H_2SO_4. $HClOAq$ is also said to yield $HClO_3Aq$ by the action of ozone. In the ordinary processes whereby $HClO_3Aq$ and $HClO_4Aq$ are obtained from $HClOAq$ (or salts of the higher acids from salts of $HClO$) much heat is produced in the decomposition of the lower acid, or salt, and O is set free at the same time; under these conditions the higher acids, or salts, are formed. When $KClOAq$ is heated $KClAq$ and $KClO_3Aq$ are produced; when $KClO_3$ is heated, O is evolved and $KClO_4$ and KCl are produced; on raising the temperature KCl remains and all the O is evolved. Thomsen (*Th.* 2, 145) gives the following thermal values for the possible reactions between Cl and K_2O:—

$$[Cl^6,3K^2OAq] = \begin{cases} 73,935 \text{ if } 3KClOAq + 3KClAq \\ 97,945 \text{ if } KClO_3Aq + 5KClAq \\ 113,315 \text{ if } 3O + 6KClAq \end{cases}$$

are formed.

Chloric acid is as strong an acid, *i.e.* its affinity is as great, as hydrochloric acid (*v.* AFFINITY, vol. i. pp. 82, 83) (*comp.* BROMINE, OXY-ACIDS OF. *v.* also HALOGEN ELEMENTS).

Detection and Estimation of salts of $HClO$, $HClO_2$, $HClO_3$, and $HClO_4$.

I. Salts of $HClO$ in solution react as oxidisers much in the same way as ClAq; on adding a little extremely dilute HNO_3Aq and distilling, a dilute solution of $HClOAq$ is obtained which (1) bleaches indigo at once, but does not bleach if As_4O_6Aq is present, (2) gives a brownish pp. of $HgO.HgCl_2$ when shaken with Hg, (3) with SO_2Aq forms a solution containing 1 equivalent HCl to 2 equivalents H_2SO_4 ($HClOAq + SO_2Aq + H_2O = H_2SO_4Aq + HClAq$). Hypochlorites may be estimated by titration with KIAq and $Na_2S_2O_3Aq$.

II. Salts of $HClO_2$ in solution react very much as mixtures of chlorates and chlorides; they are decomposed by H_2SO_4Aq (1 acid to 8-10 water) with formation of a yellow colour probably due to ClO_2 and Cl, whereas a mixture of chloride and chlorate is not decomposed. They bleach acidulated indigo at once even in presence of As_4O_6Aq. With SO_2Aq a solution is formed containing HCl and H_2SO_4 in the ratio $HCl:2H_2SO_4$ ($HClO_2Aq + 2SO_2Aq + 2H_2O = 2H_2SO_4Aq + HClAq$). Chlorites may be estimated by allowing them to oxidise a standardised acidulated solution of $FeSO_4$, and determining the residual $FeSO_4$ by $K_2Mn_2O_8Aq$.

III. Salts of $HClO_3$ in solution do not bleach acidulated dilute indigo solution in the cold until a little SO_2Aq is added (Cl is then set free);

they do not separate I at once from KIAq. They are decomposed by digestion with warm conc. HClAq; salts of $HClO_4$ are not. Chlorates may be estimated by reduction to chlorides, by Zn and H_2SO_4Aq, or by a Cu-Zn couple (*v.* Bothamley and Thompson, *C. J.* 53, 159). They may be separated from chlorites by conversion into K salts, and repeated evaporation *in vacuo* (*v.* CHLOROUS ACID AND CHLORITES). $KClO_3$ is fairly soluble in water at 15° (S = 6), and $KClO_4$ is nearly insoluble (S = 1·6); $KClO_4$ is insoluble in alcohol containing a little $K.C_2H_3O_2$; a method of separation of $KClO_3$ and $KClO_4$ may be based on these facts.

IV. Salts of $HClO_4$ are not decomposed by digestion with conc. HClAq at 100°; their solutions do not bleach acidulated indigo even in presence of SO_2Aq, nor are they reduced by a Cu-Zn couple at 100°. Perchlorates may be estimated by converting them into $KClO_4$ and determining the O in them by heating, and the K and Cl in the residue by the usual methods.

I. HYPOCHLOROUS ACID AND HYPOCHLORITES. HClOAq; MClOAq. In 1788 Berthollet obtained a liquid with bleaching properties by the action of chlorine on aqueous alkalis; Berthollet thought the liquid contained a compound of the alkali and chlorine, the latter being then regarded as oxidised hydrochloric acid. Berzelius supposed that a mixture of alkali chloride and chlorite was formed. In 1834 Balard proved that the bleaching liquid contained a salt of a new acid (Berthollet, *Statique Chimique*, 2, 183; Berzelius, *P.* 12, 529; Balard, *A. Ch.* 57, 225). The acid is known only in aqueous solutions; one salt $Ca(ClO)_2.xH_2O$ has been obtained as a solid.

Formation.—1. By the action of Cl on ZnO in presence of water; $ZnCl_2Aq$ is formed at the same time.—2. By the action of Cl on (1) $CaCO_3$ suspended in water; ($CaCO_3 + H_2O + Aq + 2Cl_2$

$= CaCl_2Aq + 2HClOAq + CO_2$):

(2) Na_2CO_3Aq; ($2Na_2CO_3Aq + 2H_2O + 2Cl_2$ $= 2NaClAq + 2HClOAq + 2NaHCO_3Aq$; then

$2NaHCO_3Aq + 2Cl_2$

$= 2NaClAq + 2CO_2 + 2HClOAq$):

(3) Na_2SO_4Aq; ($Na_2SO_4Aq + H_2O + Cl_2$ $= NaHSO_4Aq + NaClAq + HClOAq$).—3. By the action of Cl on $AgCO_3$ suspended in water; AgCl is also formed.—4. By the action of Cl on CaO_2H_2Aq; CaO_2Cl_2 and $CaCl_2$ are probably formed (*v.* p. 17); when to an aqueous solution of this product as much very dilute HNO_3Aq is added as suffices to convert less than the half of the Ca into $Ca2NO_3$, and the liquid is distilled, dilute HClOAq is obtained (Gay-Lussac, *A.* 43, 153; Schorlemmer, *B.* 6, 1509; Kopfer, *C. J.* [2] 13, 713).—5. By passing Cl_2O into H_2O, HClOAq is formed (*v.* CHLORINE MONOXIDE).—6. Addition of H_2O_2Aq (containing 2·45 p.c. H_2O_2) to a large excess of ClAq produces HClOAq, according to Fairley (*B. A.* 1874, 57); if much H_2O_2 is added, the HClOAq is decomposed forming HClAq, H_2O, and evolving O.—7. According to Odling (*J.* 1860. 65) HClOAq is formed by leading air laden with HCl into a warm solution of $K_2Mn_2O_8$ containing H_2SO_4Aq, or into a mixture of MnO_2 and H_2SO_4Aq.—8. HClOAq is also formed, along with other salts, by the action of Cl on aqueous solutions of Na_2HPO_4, $FeSO_4$, $ZnSO_4$, $MnSO_4$, $CuSO_4$, $Zn(C_2H_3O_2)_2$.—9. Alkali salts of HClO are produced by electrolysis of NaClAq or KClAq (Lidoff a. Tichomiroff, *J. R.* 1882. 212).

Preparation.—A flask of somewhat under 1000 c.c. capacity, with a good-fitting glass stopper, is filled with air-free Cl in the dark; ppd. HgO which has been heated to 300° and cooled, suspended in a little H_2O, is added, in the proportion of 15 grams to 1 litre Cl; the flask is shaken for about 15 minutes, and the liquid is poured off from the Hg_2OCl_2 formed: this solution contains from 2 to 3 p.c. of HClO (Carius, *A.* 126, 196). If the Cl used contains much air the reaction proceeds very slowly; if the HgO has not been heated to 300° much $Hg2ClO_2$ is formed. $2HgO + 2Cl_2 + H_2O + Aq = HgO.HgCl_2 + 2HClOAq$. The solution of HClOAq is best kept in contact with a little HgO; any Cl set free is thus continually converted into HClO.

Properties.—An aqueous solution of HClO smells like Cl_2O. It is very easily decomposed into Cl and $HClO_3Aq$; in sunlight this change proceeds rapidly, the more conc. the solution the more rapid is the decomposition, and traces of $HClO_4$ are also formed (Popper, *A.* 227, 161). A dilute solution of HClO may be distilled with partial decomposition, the distillate is richer in HClO; Gay-Lussac found that, on distilling a dilute solution to one-half, the distillate contained five-sixths of the total HClO (*C. R.* 14, 927). HClOAq is a monobasic acid; added to KOHAq or $Ca(OH)_2Aq$, KClOAq or $Ca(ClO)_2Aq$ is formed. Thomsen gives the heat of neutralisation as [HClOAq, NaOHAq] = 9,980, which is about $\frac{2}{3}$ of the value of the heat of neutralisation of one of the stabler monobasic acids (*e.g.* HCl, $HClO_3$, HNO_3), and is a little greater than the value for HSHAq, viz., 7,740. HClOAq does not dissolve bases insoluble in water, nor does it decompose the carbonates of these bases.

Reactions.—1. HClOAq acts generally as an *oxidiser*; it easily parts with O while HClAq remains. Thus, As is rapidly oxidised with evolution of light; P, S, Se, Br, I are converted to H_3PO_4Aq, H_2SO_4Aq, &c., even by dilute HClOAq; lower oxides or salts are converted into higher, *e.g.* SO_2Aq to H_2SO_4Aq, FeO to Fe_2O_3, As_2O_3Aq to As_2O_5Aq, $FeSO_4Aq$ to $Fe_2(SO_4)_3Aq$, Fe_2Cl_6Aq, and Fe_2O_3, $MnSO_4Aq$ to MnO_2; sulphides yield sulphates, *e.g.* H_2SAq gives H_2SO_4Aq and S; NH_3 gives N, H_2O, and NH_4ClAq; HCl forms H_2O and Cl. The quantity of the acid expressed by the formula HClO oxidises the same mass of an oxide &c. as can be oxidised by Cl_2 in presence of H_2O; thus

$$MnO + H_2O + \left\{\begin{matrix} Cl_2 \\ HClO \end{matrix}\right. = MnO_2 + \left\{\begin{matrix} 2HCl \\ HCl + H_2O. \end{matrix}\right.$$

2. On many *carbon compounds* HClOAq acts partly as an oxidising, partly as a chlorinating, agent; *e.g.* $H_2C_2O_4Aq + HClOAq = 2CO_2 + H_2O + HClAq$. Some organic compounds combine with the acid: *e.g.* $C_6H_6 + 3HClOAq = C_6H_6Cl_3(OH)_3$, $C_2H_4 + HClOAq = C_2H_4ClOH$.—3. *Indigo* solution, and various other vegetable colours, are rapidly bleached by HClOAq; one formula-weight of HClO in solution exerts as great a bleaching action as Cl_2 ($HClOAq = HClAq + O$; $Cl_2 + H_2O = 2HCl + O$).—4. HClOAq

is said to be oxidised to $HClO_4Aq$ by *ozone* (Fairley, *B. A.* 1874. 58).

Hypochlorites are very easily decomposed; even in dilute solutions boiling suffices to convert them into chlorides and chlorates, in conc. solutions boiling produces chlorides and O. Their solutions are also decomposed by heating with Co_2O_3, CuO, MnO_2 &c., O is evolved and chlorides remain; *e.g.* $Ca(ClO)_2Aq + Co_2O_3 = CaCl_2Aq + Co_2O_3 + O_2$ (CoO_3 is perhaps formed and again reduced to Co_2O_3 with evolution of O; Winkler, *J. pr.* 98, 340). As $Ca(OCl)_2Aq$ is formed by the action of Cl on CaOAq, it is easy to obtain O by leading Cl into strong warm milk of lime containing a little Co_2O_3 ($Co.2NO_3$ is used). Solutions of KClO and NaClO, along with KCl and NaCl, are obtained by leading Cl into cold dilute KOHAq or NaOHAq. Solutions of hypochlorites bleach rapidly on addition of a little HNO_3Aq, H_2SO_4Aq, HClAq, or even CO_2Aq; these solutions act as oxidisers towards P, S, I, &c. As the hypochlorites are so easily decomposed it is difficult to obtain them, even in solution, free from chlorides. Kingzett (*C. J.* [2] 13, 404) obtained crystals of nearly pure calcium hypochlorite, $CaO_2Cl_2.xH_2O$, by exhausting bleaching powder with cold H_2O, filtering, and placing the filtrate *in vacuo* over conc. H_2SO_4. The crystals very easily decomposed, even by drying *in vacuo*, with evolution of Cl. The greater part of the Cl was lost by heating the moist crystals to 100°, the residue probably contained chlorate, it also contained much carbonate. The crystals dissolved in H_2O; this solution was decomposed by CO_2 with evolution of most, but not all, of the chlorine. That an aqueous solution of bleaching powder contains CaO_2Cl_2 has been confirmed by O'Shea (*C. J.* 43, 422), who proved that when such a solution is diffused without a membrane the diffusate contains considerably less active Cl (*i.e.* Cl which is so combined with Ca and O that it is capable of bleaching), and the residue considerably more active Cl than the original liquid, in proportion to the Cl or $CaCl_2$; that [illegible] diffusion sufficed to render the diffused liquid relatively poorer in active Cl and richer in chloride.

Bleaching powder.—Cl is absorbed by slaked lime and the product possesses strong bleaching properties. Gay-Lussac regarded bleaching powder as containing $CaCl_2O_2$ and $CaCl_2$ in the ratio $CaCl_2O_2:CaCl_2$. Odling *Manual of Chem.* 1, 56) suggested the composition Ca.OClCl, chiefly because bleaching powder is not deliquescent nor is $CaCl_2$ removed rom it by treatment with alcohol. Göpner *J. pr.* [2] 7, 441) asserted bleaching powder to be a compound of CaO with Cl, and to have the composition $CaO.Cl_2$. Stahlschmidt (*B.* 8, 869) uggested the composition Ca.OH.OCl. Bleaching powder prepared by the action of pure dry Cl on pure dry $Ca(OH)_2$ always contains some $Ca(OH)_2$; but the quantity of this is variable and can be much diminished by repeated treatment with dry Cl, the $Ca(OH)_2$ is not therefore an essential part of the bleaching compound (*v.* Kopfer, *C. J.* [2] 13, 713; O'Shea, *C. J.* 43, 422; Lunge a. chäppi, *D. P. J.* 239, 63). That $CaCl_2$ is not present as such in bleaching powder is shown y the facts that it is not deliquescent, that when treated with small successive quantities of water the first washings contain much less Cl than would be the case were $CaCl_2$ present in the liquid, and that in the presence of a little moisture almost the whole of the Cl can be removed from bleaching powder by the action of CO_2 (Lunge a. Schäppi, *D. P. J.* 237, 63; *v.* also Lunge a. Naef, *B.* 16, 840).

The composition $CaO.Cl_2$ assigned by Göpner to the bleaching compound in bleaching powder was disproved by the experiments of Kopfer (*C. J.* [2] 13, 713), who showed that when an extremely dilute mineral acid (HCl, HNO_3, or H_2SO_4) is added to a solution of bleaching powder, in quantity sufficient to saturate all the lime and the $Ca(OCl)_2$ present—calculated on the assumption that the active (bleaching) Cl exists as $Ca(OCl)_2$—and the liquid is distilled, almost the theoretical quantity of HClO is obtained in the distillate. The formula Ca.OH.OCl given to the bleaching compound by Stahlschmidt assigns a limit to the amount of active Cl, *i.e.* Cl available for bleaching, in the powder: Stahlschmidt represents the formation of the bleaching powder thus—$[illegible]Ca(OH)_2 + 2Cl_2 = 2Ca.OH.OCl + CaCl_2 + 2H_2O$. The strongest bleaching powder cannot therefore contain more than about 33 p.c. of available Cl; but Lunge a. Schäppi (*D. P. J.* 237, 63) prepared bleaching powder containing 43·4 p.c. available Cl. Moreover, according to Stahlschmidt's view, when water acts on bleaching powder, the reaction is $2Ca.OH.OCl = Ca(OH)_2 + CaO_2Cl_2$; therefore no bleaching powder can be represented as containing CaO_2Cl_2 and $CaCl_2$ in a greater ratio to $Ca(OH)_2$ than 1:1:1. Now O'Shea (*C. J.* 43, 422) determined the ratio of $Ca(OCl)_2$ (supposing all available Cl to exist in this form): $CaCl_2:Ca(OH)_2$ in six samples of bleaching powder made from pure $Ca(OH)_2$; in 2 out of the 6 samples the ratio was $3CaO_2Cl_2:3CaCl_2:2Ca(OH)_2$. Finally O'Shea removed any $CaCl_2$ present as such from various samples of bleaching powder, prepared from pure $Ca(OH)_2$ by repeated treatment with alcohol, and determined the total CaO, the total Cl, and the available Cl, in the residue, *i.e.* in the bleaching compound; the results in every case were—(1) CaO : total Cl = 1:2; (2) available Cl : total Cl = 1:2; (3) CaO : available Cl = 1:1.

Stahlschmidt's formula Ca.OH.OCl requires for (1) the ratio 1:1; for (2) 1:1; for (3) 1:1.

Gay-Lussac's formula CaO_2Cl_2 requires for (1) the ratio 1:2; for (2) 1:1; for (3) 1:2.

Odling's formula Ca.OCl.Cl requires for (1) the ratio 1:2; for (2) 1:2; for (3) 1:1.

The experiments of Kingzett already referred to (*v. supra*) showed that when water acts on bleaching powder CaO_2Cl_2 is contained in the solution. There can be little doubt that the formula Ca.OCl.Cl better expresses the composition and properties of the bleaching compound in bleaching powder than any other formula yet suggested; and that the reaction which occurs when water is added to this compound is $2Ca.OCl.Cl + Aq = CaO_2Cl_2Aq + CaCl_2Aq$.

II. CHLOROUS ACID AND CHLORITES. $HClO_2Aq$; $MClO_2$. Chlorous acid is known only in aqueous solution; it is indeed doubtful whether even a solution of $HClO_2$ has been obtained free from $HClO_3$. $KClO_2$ may be prepared by adding an aqueous solution of ClO_2 of known strength to the proper quantity of KOHAq, evaporating at 45°-50° *in vacuo*, separating from $KClO_3$ which crystallises out, repeating the evaporation and separation of $KClO_3$, then adding alcohol to the mother liquor, evaporating *in vacuo*, and collecting the second crop of crystals which form (Garzarolli-Thurnlackh a. J. Hayn, *A.* 209, 203). $HClO_2Aq$ could not be obtained by the action of acids on this salt. When the gas obtained by acting on $KClO_3$ with HNO_3Aq and As_4O_6 is led into water, a yellowish-red acid solution is obtained, which on warming, or on exposure to sunlight, contains HCl and $HClO_3$. This solution when freshly prepared is generally supposed to be $HClO_2Aq$; but the experiments of Garzarolli-Thurnlackh (*v.* CHLORINE TRIOXIDE) render it almost certain that the gas obtained as above is a mixture of ClO_2 and Cl, and that the solution contains both $HClO_2$ and $HClO_3$.

The solution prepared as described reacts with many metals; *e.g.* Hg forms an oxychloride, Cu a mixture of $CuCl_2$ and $Cu(ClO_3)_2$, Zn and Pb form chlorides and probably chlorites, and finally chlorates; with the lower salts of Sn, Fe, Hg, &c., the solution reacts to form higher salts of these metals; As_2O_3Aq is not oxidised to As_2O_5Aq; HCl decomposes the solution forming Cl and H_2O, HIAq gives HCl and I; HNO_2Aq is oxidised to HNO_3Aq; SO_2Aq is oxidised to H_2SO_4Aq. According to Brandau (*A.* 151, 340) if the gas supposed to be Cl_2O_3 is led into H_2O at 0° a solid hydrate of $HClO_2$ is obtained; when pressed between paper the hydrate is a lustrous mass remaining unmelted at 10°, and volatilisable without residue. Two specimens gave 50 and 67·5 p.c. water respectively.

Chlorites. Very few of these salts have been prepared. *Potassium chlorite*, $KClO_2$, prepared as above described, forms needles, which deliquesce after standing some time in the air. The *silver* and *lead* salts, $AgClO_2$ and $Pb(ClO_2)_2$ are obtained by adding $AgNO_3Aq$ and $Pb(C_2H_3O_2)_2Aq$ respectively, to $KClO_2Aq$. $AgClO_2$ crystallises from hot H_2O in greenish-yellow scales; it is slowly decomposed in direct sunlight; SO_2Aq rapidly reduces to AgCl; dilute H_2SO_4Aq evolves a gas the colour and smell of ClO_2. $KClO_2Aq$ quickly oxidises $FeSO_4Aq$; $KClO_2$ mixed with S and rubbed ignites the S. $Pb(ClO_2)_2$ after washing with hot H_2O forms greenish-yellow scales; slightly soluble in hot H_2O; reactions similar to those of $KClO_2$; soluble in KOHAq. This solution is reduced by SO_2Aq to $PbSO_4$ and $PbCl_2Aq$ (Garzarolli-Thurnlackh a. J. Hayn, *A.* 209, 203). Millon (*A. Ch.* [3] 7, 298) described $Ba(ClO_2)_2$ and $Sr(ClO_2)_2$ as very soluble salts; probably the salts contained Ba and $Sr(ClO_3)_2$.

III. CHLORIC ACID AND CHLORATES. $HClO_3Aq$; $MClO_3$. An aqueous solution of $HClO_3$ is formed when ClO_2Aq is exposed to sunlight, or is heated. $KClO_3$ and $NaClO_3$ are produced by electrolysis of KClAq and NaClAq respectively: carbon electrodes are employed (Lidoff a. Tichomiroff, *J. R.* 1882. 341).

Preparation.—1. $Ba(ClO_3)_2$ is obtained by dissolving 8 pts. crystallised $(NH_4)_2SO_4$ and 3 pts. $KClO_3$ in 15 pts. hot H_2O, evaporating to a thin syrup, digesting for a day at a gentle heat with alcohol (80 p.c.), filtering from K_2SO_4, adding BaOAq, evaporating, and crystallising (Wittstein; *v.* also Böttger, *A.* 57, 138). A weighed quantity of the crystals of $Ba(ClO_3)_2$ is dissolved in H_2O; a quantity of dilute H_2SO_4Aq exactly sufficient to pp. all the Ba as $BaSO_4$ is added, little by little; the liquid is filtered—the filtrate must give no pp. either with BaOAq or H_2SO_4Aq—and the filtrate is concentrated *in vacuo* over H_2SO_4.—2. Hot $KClO_3Aq$ is decomposed by excess of H_2SiF_6Aq; after cooling, the liquid is filtered from K_2SiF_6 and evaporated over H_2SO_4 and KOH *in vacuo*; the excess of H_2SiF_6 volatilises and $HClO_3Aq$ remains.

Properties. — By evaporation *in vacuo* of dilute $HClO_3Aq$, a somewhat oily, colourless, strongly acid, liquid is obtained, with S.G. 1·282 at 14°; according to Kämmerer this liquid contains $HClO_3$ and H_2O in the ratio $HClO_3{:}7H_2O$; the same chemist says, that if this liquid remains longer *in vacuo*, sudden evolution of Cl and O occurs, and $HClO_3.4\frac{1}{2}H_2O$ remains (*P.* 138, 390). The strongest solution of $HClO_3$ does not solidify at −20°. $HClO_3Aq$ reddens litmus paper and then bleaches it; paper or linen soaked in fairly conc. acid and dried takes fire. Heated to about 40° the solution decomposes into $HClO_4Aq$, Cl, O, and H_2O (Serullas, *A. Ch.* 45, 204 a. 270). Thomsen gives these thermal values $[H,Cl,O^3,Aq] = 23,940$, but $[Cl^2,O^5,Aq] = -20,480$; $[HClO^3Aq, KOHAq] = 13,760$. The affinity of $HClO_3Aq$ is equal to that of the strongest acids (*v.* AFFINITY, vol. i. pp. 82, 83).

Reactions.—1. *Zinc* and *iron* dissolve in $HClO_3Aq$ with evolution of H.—2. *Iodine* is oxidised to HIO_3Aq. — 3. Oxidisable *oxygen compounds* are converted into higher compounds, *e.g.* SO_2Aq gives H_2SO_4Aq, Cl, and H_2O; H_3PO_3Aq gives H_3PO_4Aq.—4. *Chlorhydric acid* forms H_2O and Cl.—5. *Sulphuretted hydrogen* produces H_2SO_4Aq and S. — 6. *Iodine* gives HIO_3Aq; *bromine* only traces of $HBrO_3Aq$ (Kämmerer, *P.* 138, 399).—7. By *electrolysis* $HClO_3Aq$ yields first $HClO_4Aq$, and then Cl (Buff, *A.* 110, 257). — 8. *Heated* above 40° $HClO_3Aq$ decomposes into Cl, O, H_2O, and $HClO_4Aq$.

Chlorates. $HClO_3Aq$ acts as a monobasic acid. Normal chlorates are all soluble in water; $KClO_3$ is less soluble than the others. Chlorates may be prepared by acting on $Ba(ClO_3)_2Aq$ with the sulphate of the metal whose chlorate is required; many are also obtained by the action of the metallic oxide, or carbonate, on $HClO_3Aq$. Chlorates easily part with their O when heated; they act therefore as oxidisers (*v. Potassium chlorate*). Aqueous solutions are not, however, very easily reduced (*e.g.* H_2S has no action); boiled with P, chlorides are formed (Slater, *J. pr.* 60, 247); chlorates in solution are also reduced by Zn and dilute H_2SO_4Aq, and by a Cu-Zn couple. Fusible chlorates detonate when rubbed with easily combustible bodies, *e.g.* S or Sb_2S_3; sometimes violent explosions occur. H_2SO_4Aq decomposes chlorates with evolution of ClO_2 and Cl; HClAq evolves *euchlorine*, which is a mixture of ClO_2 and Cl. Solutions of chlorates do not bleach; addition of a little SO_2Aq liberates Cl and bleaching occurs.

Ammonium chlorate. $NH_4.ClO_3$. By adding NH_3Aq, or $(NH_4)_2CO_3Aq$, to $HClO_3Aq$; or $(NH_4)_2CO_3Aq$ to $Ba(ClO_3)_2Aq$ and filtering; or

$(NH_4)_2SiF_6Aq$ to $KClO_3Aq$ and filtering; the solution in each case is evaporated, the salt separates in needles. Soluble in H_2O, and alcohol; sublimes somewhat above 100°; at higher temperature decomposes to Cl, N_2O, and H_2O.

Barium chlorate.—By adding BaOAq, or $BaCO_3$, to $HClO_3Aq$. Thompson (*P. M.* [3] 31, 510) mixes solutions, each in the minimum of water, of 122 parts $KClO_3$ and 167 parts $NH_4.H.C_4H_4O_6$, removes $K.H.C_4H_4O_6$, adds alcohol, filters, decomposes the $NH_4.ClO_3Aq$ by boiling with freshly ppd. $BaCO_3$, filters and crystallises. (*v.* also Böttger, *A.* 57, 138; Brandau, *A.* 151, 361; Bolly a. Merz, *D. P. J.* 153, 358). Crystallises in 4-sided plates. S. (0°) 22·8; (40°) 52·1; (116°) 195; (135°) 287·4; (146°) 365·6; (180°) 522·6 (Tilden a. Shenstone, *T.* 175, 23).

Calcium chlorate. $Ca(ClO_3)_2$. Prepared like $Ba(ClO_3)_2$. Very deliquescent and difficult to crystallise.

Copper chlorate. $Cu(ClO_3)_2.6H_2O$. By dissolving CuO in $HClO_3Aq$ and evaporating. Green, deliquescent, octahedra; soluble in alcohol; decomposed at 100° probably forming a basic salt (Wächter, *A.* 52, 233; *v.* also Casselmann, *Fr.* 4, 24).

Lead chlorate. $Pb(ClO_3)_2$. By saturating $HClO_3Aq$ with PbO, and evaporating; hot solutions deposit rhombohedral deliquescent $Pb(ClO_3)_2.H_2O$ (Wächter, *A.* 52, 233).

Magnesium chlorate. $Mg(ClO_3)_2$. Obtained as, and closely resembles, $Ca(ClO_3)_2$.

Mercury chlorates. (1) $HgClO_3$; columnar crystals, soluble in H_2O and alcohol; by dissolving Hg_2O in $HClO_3Aq$; heated, gives HgCl, Hg, and O. (2) $Hg(ClO_3)_2$ crystallises from solution of HgO in warm $HClO_3Aq$ in needles. S. (about 15°) 25. Decomposed by heat to O, HgCl, $HgCl_2$, and a little HgO.

Potassium chlorate. $KClO_3$. By passing Cl into warm milk of lime containing KCl, and crystallising from the more soluble $CaCl_2$; purified by recrystallisation, or by rubbing with water to a thick cream, and washing with H_2O until KCl is removed (*v.* Lunge, *D. P. J.* 189, 488; Hunt, *B.* 5, 229). White, pearly, monoclinic plates. S.G. 2·35 (Kremers, *P.* 97, 1; 99, 25). S. (0°) 3·3; (15°) 6; (35°) 12; (50°) 19; (75°) 36; (104·8° = B.P.) 60. S. (120°) 73·7; (136°) 98·9; (160°) 148; (190°) 183 (Tilden a. Shenstone, *T.* 175, 23). S.G. of $KClO_3Aq$ at 19·5° (Kremers, *P.* 96, 62; Gorlach, *Fr.* 8, 290) 1 p.c. $KClO_3$ = 1·007; 2 p.c. 1·014; 3 p.c. 1·02; 4 p.c. 1·026; 5 p.c. 1·033; 6 p.c. 1·039; 7 p.c. 1·045; 8 p.c. 1·052; 9 p.c. 1·059; 10 p.c. 1·066. S. (alcohol) as follows: Gerardin *A. Ch.* [4] 5, 129).

M.P. about 359° (Carnelley, *C. J.* [2] 18, 277). Heated to about 400° evolution of O begins; if the temperature is not increased, evolution of O ceases when KCl and $KClO_4$ are formed (*v.* PERCHLORIC ACID; *Preparation*, p. 20); if the temperature is increased the whole of the O is removed and KCl remains; when the temperature is lower than that at which $KClO_4$ is decomposed the reaction approximates to that represented by the equation $8KClO_3 = 5KClO_4 + 3KCl + 2O_2$ (Teed, *C. J.* 51, 283; Frankland a. Dingwall, *C. J.* 51, 274). If $\frac{1}{2}$ pt. ppd. MnO_2, Fe_2O_3, CuO, or spongy Pt, is mixed with $KClO_3$, O is evolved at a much lower temperature; about 110°–120° with Fe_2O_3, 200°–205° with MnO_2, 230°–235° with CuO, 260°–270° with Pt black. The more finely divided the CuO the lower is the temperature at which evolution of O begins; the temperature is lowered by so little as $\frac{1}{500}$th part of very finely divided CuO, MnO_2, or Fe_2O_3, but the greater the quantity of the foreign body the more rapid is the evolution of O (Mitscherlich, *P.* 55, 220; Wiederhold, *P.* 116, 171; 118, 186; Baudrimont, *J. Ph.* [4] 14, 81 a. 161). $KClO_3$ is an energetic oxidiser; mixed with easily oxidised bodies, *e.g.* S, P, Sb_2S_3, and heated or rubbed, or sometimes even exposed to direct sunlight, explosions occur. Charcoal, S, Sb, Sb_2S_3, finely divided Fe, As, very fine Cu, &c. dropped on to molten $KClO_3$, burn with production of much light (Böttger, *A.* 57, 138). Conc. $KClO_3Aq$ boiled with P produces KClAq, K_2HPO_4Aq, and K_2HPO_3Aq: with As, KClAq and K_2HAsO_4Aq are formed (Slater, *J. pr.* 60, 247). For the action of acids on $KClO_3$ *v.* CHLORINE, OXIDES OF; CHLORINE PEROXIDE, and CHLORINE TRIOXIDE.

Rubidium chlorate. $RbClO_3$. By decomposing Rb_2SO_4Aq by $Ba(ClO_3)_2Aq$. Small trimetric crystals. S. (4·7°) 2·8; (13°) 3·9; (18·2°) 4·9; (19°) 5·1 (Reissig, *A.* 127, 33).

Silver chlorate. $AgClO_3$. A slow stream of Cl is passed into H_2O containing Ag_2O or Ag_2CO_3 in suspension; liquid is decanted from AgCl and is again treated with Cl; after standing for some time at 60°, to convert any AgClO into $AgClO_3$, liquid is evaporated at 100° (Stas, *Chem. Propert.* 90). White, opaque, non-deliquescent, trimetric, crystals. S.G. 4·93 (Schneider, *P.* 106, 226; 107, 113). S. (about 15°) 10; (about 80°–100°) 50: insoluble in alcohol. Decomposed by Cl to AgCl while $HClO_4$ remains in solution; gives AgCl and O on heating; mixed with S explodes more easily than $KClO_3$. A double salt $KClO_3.AgClO_3$ is formed by heating equivalent quantities of $KClO_3Aq$ and $AgClO_3$ to 200° in a closed tube (Pfaundler, *C. C.* 1862. 849).

Sodium chlorate. By action of Cl on warm NaOHAq; better by $KClO_3Aq + Na_2SiF_6Aq$.

S.G. of alcohol ·9951		S.G. ·9793		S.G. ·9573		S.G. ·939		S.G. ·8967		S.G. ·8429

S. (0°) 82; (40°) 123·5; (100°) 204 (Kremers, *P.* 97, 1; 99, 25). S. (alcohol, 83 p.c. 15°) 3. Resembles $KClO_3$.

Strontium chlorate. $Sr(ClO_3)_2.8H_2O$. Prepared as $Ba(ClO_3)_2$. Deliquescent needles; soluble in alcohol (Souchay, *A.* 102, 381).

Zinc chlorate. $Zn(ClO_3)_2$. By dissolving $ZnCO_3$ in $HClO_3Aq$, or decomposing $ZnSiF_6$ by $KClO_3Aq$ (Henry, *J. Ph.* 25, 265).

Thallium chlorate. By adding $TlNO_3Aq$ to $KClO_3Aq$; the solution is decomposed by heat and on evaporation $TClO_4$ separates out (Crookes, *C. N.* 8, 195). A *chlorate of ytterbium* was obtained by Popp (*A.* 131, 179).

IV. PERCHLORIC ACID AND PERCHLORATES. $HClO_4$; $MClO_4$. Mol. w. unknown for either the acid or its salts.

Stadion (*G. A.* 52, 197 a. 339) prepared potassium perchlorate by the action of H_2SO_4Aq on $KClO_3$; he obtained the acid by decomposing the new salt by H_2SO_4Aq. Serullas (*A. Ch.* [2] 45, 270; 46, 294 a. 323), prepared the same perchlorate by heating $KClO_3$ until the melted mass became semi-solid. The acid has been investigated by Roscoe (*A.* 121, 346).

Formation.—1. By heating $HClO_3Aq$, O and Cl being also evolved (Serullas, *l.c.*).—2. By the electrolysis of ClAq, or HClAq (Riche, *C. R.* 46, 348).—3. By electrolysis of $KClO_3Aq$, with Pt electrodes, ozone is evolved and $KClO_4$ and traces of KCl are formed (Lidoff a. Tichomiroff *J. R.* 1882. 341).—4. By adding ozone to HClOAq Fairly (*B. A.* 1874. 58).

Preparation.—1. $KClO_4$ is prepared by fusing $KClO_3$ until the liquid mass becomes pasty; $2KClO_3 = KClO_4 + KCl + O_2$. Marignac (*B. J.* 24, 192) says that when 6½ litres O are evolved from 100 grams of $KClO_3$ the residue contains 65-66 p.c. $KClO_4$. The fused mass is repeatedly digested at 100° with conc. HClAq, to decompose $KClO_3$; the residue is dissolved in the smallest quantity of boiling H_2O; the crystals which separate on cooling are again digested with HClAq at 100°, and crystallisation is repeated from boiling water. Pure $KClO_4$ gives no yellow colour on digestion with conc. HClAq. One part $KClO_4$ is distilled with 4 parts very conc. pure H_2SO_4 so long as the distillate solidifies in the receiver; the crystalline distillate is melted, poured into a small retort, and gradually heated to 110° when yellowish fumes come off and a brownish-yellow distillate is formed. This distillate is redistilled very slowly and cautiously, heating being stopped whenever crystals begin to form in the neck of the retort. The distillate is preserved in small sealed glass bulbs.—2. 606 grams $KClO_3$ are boiled with the H_2SiF_6Aq prepared from 1000 grams CaF_2; after cooling, the K_2SiF_6 is filtered off; the solution of $HClO_3Aq$ is heated until white fumes of $HClO_4$ appear; the liquid is then slowly distilled from a retort; the distillate is freed from HClAq and H_2SO_4Aq by shaking with $AgClO_4$ and $Ba(ClO_4)_2$, filtered, and again distilled. From this $HClO_4Aq$, the pure acid may be obtained by distilling with 4 volumes conc. H_2SO_4, and rectifying as described in 1 (Roscoe, *A.* 121, 346).

The first product of the action of H_2SO_4 on $KClO_4$ is nearly pure $HClO_4$; this is succeeded by a liquid containing 72·4 p.c. $HClO_4$, when this drops into the receiver crystals of $HClO_4.H_2O$ are formed. When these crystals are slowly heated $HClO_4$ distils over, but after a time the liquid containing 72·4 p.c. $HClO_4$ is formed in the retort, and coming into contact with the $HClO_4$ forms crystals of $HClO_4.H_2O$.

Properties.—$HClO_4$ is a colourless, oily, volatile, liquid; S.G. 1·782 at 15°. Fumes strongly in moist air. Very easily undergoes decomposition with explosion, even when kept in glass bulbs in the dark. Cannot be distilled without decomposition; at 75° change begins; at 92° white clouds come off, and a yellow gas smelling like ClO_2, also a few drops of a liquid resembling Br; at a higher temperature violent explosion occurs; the residue solidifies to white crystals with 87·76 p.c. $HClO_4$ (Roscoe). $HClO_4$ is an extremely powerful oxidiser; one drop on charcoal, paper, wood, &c., produces combustion with violent explosions. A drop falling on to the skin produces a severe wound. When the hydrate $HClO_4.H_2O$ (*v. Combinations*, No. 1) is distilled under ordinary pressure nearly pure $HClO_4$ passes over at 110°. The temperature then rises until 203° is reached, when it becomes constant, and a heavy oily liquid, exactly resembling conc. H_2SO_4, distils over; the same liquid is obtained by distilling $HClO_4Aq$ until 203° is reached. This liquid contains 72·1 p.c. $HClO_4$, and does not correspond to a definite hydrate ($HClO_4.2H_2O = 73·6$, $HClO_4.3H_2O = 65·05$, p.c. H_2O) (Roscoe, *l.c.*; *v.* also Weppen, *A.* 29, 318).

Reactions and Combinations.—1. $HClO_4$ combines with water with a hissing sound and production of much heat; Berthelot gives $[HClO_4,Aq] = 20,300$ (*A. Ch.* [5] 27, 214). If water is added little by little, crystals of the hydrate $HClO_4.H_2O$ are obtained; these melt at about 50°; S.G. (liquid) 1·81 at 50°; decomposition into $HClO_4$ and $HClO_4.xH_2O$ begins at 110°.—2. $HClO_4Aq$ is not reduced by H_2S, SO_2, or HNO_2Aq, nor by any known substance according to Berthelot (*Bl.* [2] 38, 1).—3. $HClO_4Aq$ dissolves Zn and Fe with evolution of H.

Perchlorates.—$HClO_4$ is a monobasic acid forming one series of salts, $MClO_4$ or $M^{II}(ClO_4)_2$; a few basic salts are also known, *e.g.* $BiO.ClO_4$. These salts are prepared by the action of $HClO_4Aq$ on metals, oxides, or carbonates; or by the decomposition of $Ba(ClO_4)_2Aq$ by sulphates; or by the decomposition of chlorates by heat (*v.* POTASSIUM CHLORATE), or by H_2SO_4Aq, or by HNO_3Aq (Penny, *A.* 37, 203). The perchlorates are generally easily soluble in water; $KClO_4$ is one of the least soluble of the salts. They are isomorphous with the permanganates. They are decomposed by heat into chlorides and O, or into oxides, Cl, and O, but at higher temperatures than chlorates. When $KClO_4$ is heated so as to evolve only a part of its O, some $KClO_3$ is formed (Frankland a. Dingwall, *C. J.* 51, 278; Teed, *C. J.* 51, 283). Conc. H_2SO_4 forms $HClO_4$ at 100°; conc. HClAq does not act on perchlorates at 100°. Solutions of perchlorates are very slowly, if at all, reduced by reagents which readily reduce chlorates.

The following perchlorates have been prepared: $NH_4.ClO_4$ (Roscoe), isomorphous with $KClO_4$; $Ba(ClO_4)_2$ (Groth, *P.* 133, 226; Potilitzin, *C. C.* 1887. 1218); $Cd(ClO_4)_2$, very deliquescent (Serullas, *A. Ch.* [2] 45, 270; 46, 294 a. 323);

$Ca(ClO_4)_2$, very deliquescent (Serullas, *l.c.*); $Cu(ClO_4)_2$, large, blue, deliquescent crystals (Serullas, Roscoe); $Fe(ClO_4)_2$, long colourless needles, stable in air (Serullas); $Fe(ClO_4)_2.3H_2O$, greenish, very deliquescent, crystals (Roscoe); $Mn(ClO_4)_2$, deliquescent, not obtained in crystals (Serullas); $HgClO_4$, non-deliquescent needles (Serullas); $HgClO_4.1\frac{1}{2}H_2O$, very deliquescent (Roscoe); $Hg(ClO_4)_2$ (Serullas); $KClO_4$ (*v.* $HClO_4$, *Preparation*); S. (15°) 1·6, nearly insoluble in alcohol; $AgClO_4$ (Serullas); $NaClO_4$ (Penny, *A.* 37, 203); $TlClO_4$ decomposes in moist air (Crookes, *C. N.* 8, 195); $Zn(ClO_4)_2$ deliquescent needles. M. M. P. M.

CHLORINE, SULPHIDE OF, better called Sulphur chloride; *v.* SULPHUR.

CHLORITES — *Salts of Chlorous acid, v.* CHLORINE, OXY-ACIDS OF, p. 18.

CHLORO-. *Use of this prefix applied to inorganic compounds*; for *Chloro- compounds* and *Chloro- salts v.* the element the chloro- compound of which is sought for, or the salts to the names of which *Chloro-* is prefixed. Thus *Chloro-phosphide of nitrogen* will be found under NITROGEN, and *Chloro-platinate of potassium* under PLATINATES.

CHLORO-ACETAL *v.* CHLORO-ACETIC ALDEHYDE and CHLORAL.

CHLORO-ACETAMIDE *v.* CHLORO-ACETIC ACID, and ACETO-CHLORO-AMIDE, vol. i. p. 5.

CHLORO-ACETAMIDO- *v.* CHLORO-AMIDO-.

CHLORO-ACETANILIDE *v.* CHLORO-ANILINE.

p-Chloro-acetanilide *v.* ANILINE, vol. i. p. 274.

CHLORO-ACETENE. Is merely a mixture of aldehyde, paraldehyde, and $COCl_2$ (Kekulé a. Zincke, *A.* 162, 141; *cf.* Harnitzky, *A.* 111, 192).

CHLORO - ACETIC ACID $C_2H_3ClO_2$ *i.e.* $CH_2Cl.CO_2H$. Mol. w. 94·5. [63°]. An unstable modification [52°] (Tollens, *B.* 17, 664). (186°). S.G. $\frac{73}{19}$ 1·366.

Formation.—1. From ethylene and chlorine peroxide (Fürst, *B.* 11, 2188; *A.* 206, 78).—2. Together with AcCl by the action of chlorine on acetic anhydride (Gal, *A.* 122, 374).—3. By passing chlorine into acetyl chloride mixed with iodine and decomposing the product with water (Jazukowitsch, *Z.* 1868, 234).—4. Chloro-acetyl chloride is formed, together with di-chloro-acetyl chloride, by boiling AcCl (40g.) with PCl_5 (200g.) for some weeks (Michael, *J. pr.* [2] 35, 95).

Preparation.—1. Dry chlorine is passed into a retort containing acetic anhydride heated to 100°, dry acetic acid being simultaneously run in. The acetyl chloride which is formed:

$$(CH_3.CO)_2O + Cl_2 = CH_2Cl.CO_2H + CH_3.CO.Cl$$

is at once reconverted by the acetic acid into anhydride, which is again attacked by the chlorine, and so on, so that a small quantity of anhydride suffices for the chlorination of a large quantity of acetic acid. When the absorption of the chlorine slackens the mixture is fractionally distilled (Hentschel, *B.* 17, 1286; *cf.* R. Hoffmann, *A.* 102, 1).—2. By passing chlorine through a heated mixture of 50 g. iodine and 500 c.c. nearly glacial acetic acid S.G. 1·065. The rectified product contains a little iodo-acetic acid (Hugo Müller, *C. J.* 17, 398).

Properties.—Deliquescent trimetric tablets or needles. Blisters the skin; nearly inodorous. V. sol. water, with absorption of heat.

Reactions.—1. ***Water*** slowly converts it on heating into glycollic acid (Buchanan, *B.* 4, 340, 863). *Caustic potash* acts similarly, while baryta forms di-glycollic acid $C_4H_6O_5$ (Kekulé, *A.* 105, 288; *cf.* Schwab, *R. T. C.* 2, 46).—2. Chloro-acetic acid (10 g.) boiled with PCl_5 (88 g.) yields tetra-chloro-ethylene and other bodies (Michael, *Am.* 9, 216).—3. *Sodium-amalgam* partially reduces it to acetic acid.—4. By heating with *dimethylaniline* it is broken up into methyl chloride and CO_2; this decomposition is produced by the intermediate formation of the body $PhMe_2ClN.CH_2.CO_2H$, which splits up into CO_2, CH_3Cl, and dimethylaniline (Silberstein, *B.* 17, 2661).

Salts.—KA′ $1\frac{1}{2}$aq: laminæ, v. sol. water but not deliquescent and not dehydrated at 100°, but converted into glycollic acid at a higher temperature. The same change takes place when its aqueous solution is evaporated even below 100°.—KHA'_2: small pearly crystals, sl. sol. water.—BaA'_2aq: prisms. Decomposed but slightly when its aqueous solution is evaporated, and separates almost completely on cooling a hot saturated solution.—AgA′: pearly scales; detonates at 110°–120°.

Methyl chloro-acetate $CH_2Cl.CO_2Me$ (130°) (Schreiner, *A.* 197, 1). V.D. 3·71 (for 3·74). S.G. ^{15} 1·22; ^{19} 1·235 (Henry, *C. R.* 101, 250). S.H. ·389 (R. Schiff, *G.* 17, 286). Prepared by passing HCl into a solution of chloro-acetic acid in MeOH (Henry, *B.* 6, 743) or from $CH_2Cl.CO.Cl$ and MeOH (P. J. Meyer, *B.* 8, 1152). Insol. water. Converted by ammonia into chloro-acetamide.

Chloro-methyl ether $CH_2Cl.CO_2.CH_2Cl$. (197°). S.G. $\frac{10·6}{10·6}$ 1·322. From $CH_2Cl.CO.Cl$ and glycolic chlorhydrin (Henry, *C. R.* 97, 1308).

Ethyl ether $CH_2Cl.CO_2Et$. Mol. w. $122\frac{1}{2}$. V.D. 4·24 (calc. 4·23). (143°) (Schreiner, *A.* 197, 1); (144·5°) (Schiff, *A.* 220, 108). S.G. $\frac{20}{4}$ 1·1585 (Brühl, *A.* 203, 21). S.H. ·401. μ_β 1·428. R_∞ 43·51. S.V. 123·1.

Formed by mixing chloro-acetyl chloride with alcohol in the cold (Willm, *A. Ch.* [3] 49, 97; *A.* 102, 109); or by heating chloro-acetic acid (200 g.) with alcohol (120 g.) and H_2SO_4 (25 g.) for 6 hours at 100° (Conrad, *A.* 188, 218). Oil with ethereal odour. With ammonia it forms chloro-acetamide. It unites with Me_2S at 100° forming the hydrochloride of di-methyl-thetine (Crum Brown a. Letts, *Pr. E.* 28, 583).

Chloro-acetic ether (2 mols.) heated with (1, 3, 4) tolylene-diamine (3 mols.) at 100° forms oxy-toluquinoxaline dihydride thus:

$$3C_6H_3Me(NH_2)_2 + 2CH_2Cl.CO_2Et = 2C_6H_3Me\left\langle\begin{matrix}NH.CH_2\\NH.CO\end{matrix}\right\rangle + C_6H_3Me(NH_2Cl)_2 + 3HOEt.$$

When, however, chloro-acetic ether (2 mols.) is heated with a smaller quantity (1 mol.) of tolylene-diamine at 100° a compound $C_{13}H_{16}N_2O_3$ [147°] is formed; it may be

$$C_6H_3Me\left\langle\begin{matrix}NH.CH_2\\N(CH_2.CO_2Et)\end{matrix}\right\rangle CO$$

(Hinsberg, *A.* 237, 361).

Chloro-ethyl ether $CH_2Cl.CO_2.CH_2.CH_2Cl$. (198° uncor.). S.G. $\frac{10·6}{}$ 1·322. From chloro-acetyl chloride and glycolic chlorhydrin (Henry, *C. R.* 97, 1308). Also from ethylene and Cl_2O (Mulder a. Bremer, *B.* 11, 1958).

Propyl ether $CH_2Cl.CO_2Pr$. (161°) (Schreiner, *A.* 197, 1). S.G. ^{0} 1·11 (Henry, *J. pr.* [2] 31, 127). S.H. ·422 (Schiff, *G.* 17, 486).

n-Butyl ether $CH_2Cl.CO_2C_4H_9$. (175°). S.G. ^{0} 1·103; ^{15} 1·081. V.D. 5·1 (Gehring, *Bl.* [2] 46, 146; *C. R.* 102, 1399).

Isoamyl ether $CH_2Cl.CO_2C_5H_{11}$. (190°). S.G. ^{0} 1·063 (Hugounenq, *Bl.* [2] 45, 328).

sec-Octyl ether $CH_2Cl.CO_2C_8H_{17}$. (234°). S.G. ^{10} ·990. From octyl alcohol of castor oil (Gehring, *C. R.* 104, 1000).

Phenyl ether $CH_2Cl.CO_2Ph$. [40°]. (230°–235°). From phenol and chloro-acetyl chloride. Needles (Prevost, *J. pr.* [2] 4, 379).

Benzyl ether CH_2PhA'. (148°) at 9 mm. S.G. $\frac{4}{4}$ 1·222.

Chloride v. CHLORO-ACETYL CHLORIDE.

Amide $CH_2Cl.CO.NH_2$. *Chloro-acetamide.* [119°] (Menschutkin a. Jermolajeff, *Z.* [2] 7, 5); [116°] (Bauer, *A.* 229, 165). (225°). S. 10 at 24°. S. (alcohol) 9·5 at 24°. From chloro-acetic ether and aqueous or gaseous NH_3, or from chloro-acetyl chloride and dry ammonia (Willm, *A. Ch.* [3] 49, 99). Thick monoclinic prisms or flat plates (from alcohol). Its aqueous solution after treatment with HgO deposits slender needles of $Hg(NH.CO.CH_2Cl)_2$. Alcoholic KCy forms $C_{14}H_{18}Cl_8N_4O_5$ (?) (Schiff a. Speciale, *G.* 9, 335). Br and KOHAq give chloro-methyl-chloro-acetyl-urea $CH_2Cl.NH.CO.NH.CO.CH_2Cl$. (Wallach, *A.* 184, 30).

Anilide $CH_2Cl.CO.NPhH$. [134°]. From aniline and ethereal $CH_2Cl.COCl$ (Wallach a. Kamensky, *A.* 214, 221; Tommasi, *Bl.* 19, 400; Cech, *B.* 10, 1376; Meyer, *B.* 8, 1152). Crystallises from benzene. When treated with PCl_5 it gives off HCl and forms a base whose hydrochloride is insol. water, benzene or ether, but crystallises from alcohol in long yellow silky needles which appear to be $C_{16}H_{12}Cl_2N_2HCl$.

p-Toluide $CH_2Cl.CONHC_6H_4Me$. [162°] (Meyer; Tommasi, *C. J.* 26, 911; 27, 628).

Nitrile $CH_2Cl.CN$. (124°). S.G. ^{20} 1·193. V.D. 2·62. From the amide and P_2O_5. The yield is 50 p.c. of the theoretical (Bisschopinck, *B.* 6, 732; Engler, *B.* 6, 1003; Bauer, *A.* 229, 165).

Di-chloro-acetic acid $C_2H_2Cl_2O_2$ *i.e.* $CHCl_2.CO_2H$. (190°). S.G. ^{15} 1·522.

Formation.—1. By the chlorination of acetic or of chloro-acetic acid (Maumené, *Bl.* [2] 1, 417). 2. By the action of aqueous KCy upon chloral (Wallach, *A.* 173, 295).

Preparation.—By boiling chloral hydrate (50 g.) with water (250 g.) and K_4FeCy_6 (84 g.); the resulting potassium salt being extracted by alcohol (Wallach, *B.* 9, 1212; 10, 1526).

Properties.—Corrosive liquid; solidifies below 0°.

Reactions.—1. Converted into glyoxylic acid by heating with moist Ag_2O. The same reaction is slowly effected by water at 100°, and by alkalis (Beckurts a. Otto, *B.* 14, 583).

Salts.—KA′: laminæ (from alcohol).—AgA′: prisms, sl. sol. cold water; decomposes violently at 80°.—CaA'_2 3 aq: needles (from alcohol).—$Na(UrO)_2A'_3$ (Clarke a. Owens, *B.* 14, 35).

p-Toluidine di-chloro-acetate $C_6H_4Me.NH_3O.CO.CHCl_2$: [136°]; white needles (Duisberg, *B.* 18, 194).

Methyl ether $CHCl_2.CO_2Me$. (144°) (Wallach, *A.* 173, 299). S.G. ^{19} 1·380 (Henry, *C. R.* 101, 250). S.H. ·322 (Schiff, *G.* 17, 286).

Ethyl ether $CHCl_2.CO_2Et$. (157°). S.G. $\frac{15}{4}$ 1·2821 (Brühl, *A.* 203, 22). μ_β 1·444. R_∞ 52·19. V.D. 5·38 (for 5·42). S.H. ·388 (S.). S.V. 143·4. *Formation.*—1. Together with glyoxylic ether by heating C_2Cl_4 with NaOEt at 100°–150° for 13 hours.—2. By adding chloral hydrate (1 mol.) to potassium cyanide (1 mol.) in absolute alcohol:

$$CCl_3.CH(OH)_2 + EtOH + KCN$$
$$= CHCl_2.CO_2Et + HCN + KCl + H_2O.$$

Or by gently heating chloral cyanhydrin (1 mol.) with alcoholic NaOEt (Wallach, *B.* 6, 114; 10, 1527, 2120). *Reactions.*—1. Boiling alcoholic KCy gives acetic and oxalic acids (Claus, *B.* 11, 496, 1044).—2. *Silver*, or Na, converts it into maleic ether. 3. Alcoholic KOH gives glycollic acid (Claus, *B.* 14, 1066).

Propyl ether $CHCl_2.CO_2Pr$. S.H. ·352.

Isobutyl ether $CHCl_2.CO_2CH_2Pr$. (183°).

s-Octyl ether $CHCl_2.CO_2C_8H_{17}$. (244°) (Gehring, *C. R.* 104, 1000).

Benzyl ether $CHCl_2.CO_2.CH_2Ph$. (179°) at 60 mm. S.G. $\frac{4}{4}$ 1·313 (Seubert, *B.* 21, 281).

Amide $CHCl_2.CONH_2$. [98°] (Hantzsch a. Zeckendorff, *B.* 20, 1309). (234°). From the ether and alcoholic NH_3, or from chloral cyanhydrin $CCl_3.CH(OH).CN$ and aqueous NH_3 (Pinner a. Fuchs, *B.* 10, 1066). Monoclinic columns. V. sol. hot water. It unites with chloral forming $CCl_3.CH(OH).NH.CO.CHCl_2$, which crystallises from water in prisms. PCl_5 converts it into $CHCl_2.CCl:N.POCl_2$ (Wallach, *A.* 184, 28).

Ethylamide $CHCl_2.CONHEt$. [59°]. (226°). Converted by PCl_5 into $CHCl_2.CCl_2.NEt.POCl_2$ (140°–150°) and $CHCl_2.CCl:NEt$ (c. 163°).

Anilide $CHCl_2.CO.NHPh$. [118°]. *Formation.*—1. By the action of aniline on chloral in presence of KCy or on chloral cyanhydrin (Cech, *B.* 9, 337; 10, 1265).—2. From aniline, di-chloro-acetic acid, and P_2O_5 (C.).—3. By warming di-chloro-acetamide with aniline (C.). *Properties.* Crystalline scales (from water); sl. sol. hot water; sol. KOHAq and reppd. by acids.

Nitrile $CHCl_2.CN$. (113°). V.D. 3·82. S.G. ^{11} 1·374 (Bisschopinck, *B.* 6, 732). Formed by distilling the amide with P_2O_5. Absorbs HCl forming a crystalline compound which, when heated in a sealed tube at 140°, splits up into HCl and a *polymeride* of dichloro-acetonitrile [70°] (Weddige a. Körner, *J. pr.* [2] 31, 176).

Di-chloro-ortho-acetic ether $CHCl_2.C(OEt)_3$. (205°). Formed together with other bodies by heating C_2Cl_4 with NaOEt at 100°–120°. Decomposed by water. Decomposed by NaOEt into NaCl and di-ethyl-glyoxylic ether (Geuther a. Brockhoff, *J. pr.* [2] 7, 101).

Tri-chloro-acetic acid $C_2HCl_3O_2$ *i.e.* $CCl_3.CO_2H$. Mol. w. 163½. [55°]. (195°). S.G. $\frac{46}{15}$ 1·617. V.D. 5·3. *Formation.*—1. By the action of dry chlorine (3 mols.) on glacial acetic acid (1 mol.) in sunshine (Dumas, *A. Ch.* [2] 73, 75).—2. By the oxidation of chloral with HCl and $KClO_3$, and of chloral or metachloral with fuming HNO_3 (Kolbe, *A.* 54, 182).—3. Together with C_2Cl_6 by passing chlorine into C_2Cl_4 under water in sunlight (K.). 4. From $CCl_3.CO.Cl$, which is formed by chlorinating ether (Malaguti, *A. Ch.* [3] 16, 10).

Preparation.—1. Chloral hydrate (165½ pts.) is just melted and fuming HNO_3 (63 pts.) is added. The reaction proceeds without application of heat, and after half an hour the liquid is fractionally distilled (De Clermont, *A. Ch.* [6] 6, 135;

[5] 2, 401; *C. R.* 73, 112, 501; 74, 942; 76, 774; 81, 1270; *cf.* Tommasi a. Meldola, *C. J.* 27, 314; Judson, *Z.* [2] 7, 40).—2. Chloral hydrate (165 g.) is mixed with $KClO_3$ (37½ g.); as soon as the mixture is melted a violent action sets in, with evolution of gas, and potassium tri-chloro-acetate (120 g.) is formed (Seubert, *B.* 18, 3336, 3339).

Properties.—Deliquescent rhombohedral scales. V. sol. water. Blisters the skin. Its vapour is pungent. Markedly exhibits superfusion.

Reactions.—1. Conc. H_2SO_4 forms CO, CO_2, and HCl.—2. Both the acid and its salts are decomposed by boiling with *water* or *alkalis* into CO_2 and chloroform. *Ammonia, dimethyl-aniline*, and KCy also liberate chloroform (Silberstein, *B.* 17, 2664; Bourgoin, *Bl.* 37, 403; *C. R.* 94, 448).—3. It is *reduced* to acetic acid by fuming HI at 100° (Clermont), by electrolysis (K.), or, in aqueous solution, by (⅔ p.c.) potassium amalgam (Melsens, *A. Ch.* [3] 10, 233).—4. NaOEt forms sodium chloride, carbonate, and formate.—5. K_2SO_3Aq for $CHCl(SO_3K)CO_2K$ 1½aq (Rathke, *A.* 161, 149).—6. Forms a compound with *aluminum chloride*, which is decomposed by steam thus: $(CCl_3.CO_2)_2Al_2Cl_4 + 6H_2O = 2CHCl_3 + 2CO_2 + 4HCl + Al_2(OH)_6$ (Elbs a. Tölle, *J. pr.* [2] 32, 624).

Salts.—KA'aq: long slender needles. Heated with bromine it forms CO_2, KBr, and $CBrCl_3$ (Van 't Hoff, *B.* 10, 678).—KHA'_2: octahedra: S. 26·1 at 0°; 33·75 at 20° (Seubert).—NaA' 3aq. On dry distillation it gives NaCl, CO, CO_2, $COCl_2$, tri-chloro-acetyl chloride, tri-chloro-acetic acid and its anhydride, and a little C_2Cl_6 (Henry, *B.* 12, 1844).—NH_4A' 2aq: [80°]; prisms. Boils at 110°-115°, giving off chloroform and ammonium bi-carbonate, and leaving NH_4A', which is solid at 160°, but at a higher temperature splits up into NH_4Cl, CO, and $COCl_2$ (M.).—$NH_4HA'_2$: octahedra—LiA' 2aq: deliquescent prisms—TlA'—$TlHA'_2$—AgA': laminæ, sl. sol. water; explodes when heated, forming AgCl, CO, CO_2, and tri-chloro-acetic anhydride.—CaA'_2 6aq: prismatic needles.—CaA'_2 3½aq.—SrA'_2 6aq: radiate groups of prisms.—BaA'_2 6aq: very thin laminæ.—MgA'_2 4aq.—ZnA'_2 6aq: laminæ.—CuA'_2 6aq (Judson, *B.* 3, 782).—HgA'_2: prismatic needles.—$Hg_2A'_2$: small needles, sl. sol. water.—PbA'_2aq: large prisms, v. sol. water, sl. sol. alcohol.

Methyl ether $CCl_3.CO_2Me$. (154°) (Henry, *C. R.* 101, 250). S.G. ^{19} 1·489. S.H. ·277 (Schiff, *G.* 17, 286). Obtained by distilling the acid with methyl alcohol and H_2SO_4; or by the action of methyl alcohol on the chloride of chlorinated aldehyde. Oil, smelling of peppermint.

Tri-chloro-methyl ether $CCl_3.CO.OCCl_3$. S.G. ^{18} 1·705. (c. 200°). From the preceding or from methyl acetate by chlorine in sunshine. Said to be identical with the penta-chloro-ethyl ether of chloro-formic acid $Cl.CO.O.CCl_2.CCl_3$, (180°-185°), S.G. ^{10} 1·724 (Cahours, *A.* 64, 315). Decomposed by moist air and by aqueous alkalis into HCl, CO_2, and tri-chloro-acetic acid. *Reactions.*—1. *Ammonia* gives tri-chloro-acetamide.—2. *Alcohol* gives tri-chloro-acetic ether and chloro-formic ether; methyl alcohol acts similarly.—3. Its vapour passed through a *red-hot tube* gives $COCl_2$ and tri-chloro-acetyl chloride.

Ethyl ether $CCl_3.CO_2Et$. (167°). S.G. $\frac{20}{4}$ 1·3826 (Brühl). μ_β 1·4567. R'_∞ 60·57. S.H. ·296. V.D. 6·59 (for 6·61). S.V. 163·8 (Schiff). Obtained by distilling the acid with alcohol and a little H_2SO_4 (Clermont, *A. Ch.* [6] 6, 241). Oil, smelling of peppermint. Heated with KCy and absolute alcohol it yields CO_2 and chloroform (Claus, *A.* 191, 58). PCl_5 at 150° forms EtCl, $POCl_3$, and $CCl_3.COCl$ (Michael, *Am.* 9, 213). Heated with NaOEt (containing NaOH) it forms orthoformic ether, NaCl, and $NaEtCO_3$ (Klien, *J.* 1876, 521). With K_2SO_3 it forms $CHCl(SO_3K)_2CO_2K$ 1½aq (Rathke, *A.* 161, 166).

Penta-chloro-ethyl ether $CCl_3.CO_2C_2Cl_5$. (245°). S.G. ^{25} 1·79 (Malaguti, *A. Ch.* [3] 16, 57; Cloez, *A. Ch.* [3] 17, 304). Formed by passing chlorine through acetic ether, finally in sunshine (Leblanc, *A. Ch.* [3] 10, 200). Liquid, gradually decomposed by moist air into HCl and tri-chloro-acetic acid. *Reactions.*—1. *Alcohol* forms tri-chloro-acetic ether.—2. *Ammonia* forms tri-chloro-acetamide. 3. Prolonged action of *chlorine* forms C_2Cl_6.—4. Passage through a tube at 400° yields tri-chloro-acetyl chloride.

Propyl ether $CCl_3.CO_2Pr$. (187°) (Clermont, *C. R.* 96, 437). S.H. ·306.

Isobutyl ether $CCl_3.CO_2.CH_2Pr$. (188°) (J.).

Isoamyl ether $CCl_3.CO_2C_5H_{11}$. (217°) (C.).

s-Octyl ether $CCl_3.CO_2C_8H_{17}$. (260°) (Gehring, *C. R.* 104, 1001). Light oil.

Benzyl ether CH_2PhA'. (179°) at 50° mm. S.G. $\frac{4}{4}$ 1·389.

Anhydride $(CCl_3.CO)_2O$. (224°). Formed by treating the acid with PCl_3 or $CCl_3.COCl$ (Buckney a. Thomsen, *B.* 10, 698; Clermont, *Bl.* [2] 30, 505; *C. R.* 86, 337). Hygroscopic liquid, rapidly converted into the acid by water.

Chloride v. Tri-CHLORO-ACETYL CHLORIDE.

Amide $CCl_3.CO.NH_2$. Mol. w. 162½. [136°]. (239°). Formed by the action of ammonia on tri-chloro-acetyl chloride, on tri-chloro-acetic ether, on perchlorinated acetic ether (*v. supra*), and on perchlorinated formic, carbonic, oxalic, and succinic ethers (Malaguti, *A.* 56, 286; Cloez, *A.* 60, 261, *A. Ch.* [3] 19, 352; Gerhardt, *Compt. Chim.* 1848, 277). *Preparation.*—By mixing NH_3 (1 pt.) dissolved in alcohol (10 pts.) with trichloracetic ether (11 pts.) dissolved in alcohol (16 pts.). The mixture is kept cool. After 12 hours the reaction is complete (A. Weddige, *J. pr* [2] 33, 78). *Properties.*—Monoclinic tables (from water); sweetish taste. Sl. sol. water, v. sol. alcohol and ether. *Reactions.*—1. *Ammonia* forms ammonium tri-chloro-acetate.—2. P_2O_5 gives the nitrile.—3. PCl_5 gives $CCl_3.CCl{:}N.POCl_2$ [c. 81°] (c. 257°) (Wallach, *A.* 184, 23).

Chloro-amide $CCl_3.CO.NHCl$. [121°]. Formed by the action of chlorine-water on tri-chloracetamide (Cloez, *A. Ch.* [3] 17, 305). Very volatile with steam. Large plates. Sol. alcohol, and ether, sl. sol. water. It dissolves in NH_3Aq with re-formation of tri-chlor-acetamide. It is scarcely altered by boiling with alcoholic KOH. By neutralising the alcoholic solution of the chloro-amide with alcoholic KOH a well crystallised potassium salt ($CCl_3.CO.NClK$) is formed (Steiner, *B.* 15, 1606).

Methylamide $CCl_3.CONHMe$. [106°]. From tri-chloro-acetic ether and methylamine. Crystals, sl. sol. water and ether, slowly attacked by HNO_3 (Franchimont a. Klobbie, *R. T. C.* 6, 234).

Di-methyl-amide $CCl_3.CONMe_2$. [c. 12°].

(238°). S.G. ^{15} 1·441. V.D. 6·68. Not attacked by HNO_3 (S.G. 1·53) (F. a. K.).

Ethyl-amide $CCl_3.CO.NHEt$. [74°]. (230°). Quadrangular tables. Insol. cold water, v. sol. alcohol, ether, or chloroform (Wallach a. Kamensky, *A.* 214, 225). PCl_5 appears to form the imido-chloride $CCl_3CCl{:}NEt$, but this gives no basic condensation product.

Di-ethyl-amide $CCl_3.CONEt_2$. [27°], (F. a. K.); [90°] (Cloez). V.D. 7·23 (F. a. K.). From hexa-chloro-acetone and NEt_2H (Cloez, jun., *A. Ch.* [6] 9, 145). Crystals. Not attacked by pure HNO_3 (S.G. 1·53) (F. a. K.).

Allyl-amide $CCl_3.CO.NHC_3H_5$. [45°]. (190°). From allylamine and hexa-chloro-acetone (Cloez).

Anilide $CCl_3.CO.NPhH$. [94°]. Scales (from alcohol); gives no basic condensation product with PCl_5.

o-Toluide $CCl_3.CO.NH.C_6H_4Me$. [67°]. (215°). From hexa-chloro-acetone and *o*-toluidine (Cloez, jun., *A. Ch.* [6] 9, 145).

p-Toluide $CCl_3.CO.NH.C_6H_4Me$. [80°]. (185°) (Cloez).

Nitrile $CCl_3.CN$. (84°). S.G. ^{12} 1·439. V.D. 5·03. Formed by the action of chlorine on acetonitrile containing iodine (Beckurts, *B.* 9, 1594). From the amide and P_2O_5; the yield is 90 p.c. (Dumas, Malaguti, a. Leblanc, *C. R.* 25, 442; Bisschopinck, *B.* 6, 732; Bauer, *A.* 229, 165). Pungent liquid, insol. water, sol. alcohol, ether, and light petroleum. Forms a crystalline compound with HBr which is decomposed by water. Warmed with HCl changes to trichloro-acetic acid. Polymerises when kept. NaOEt forms ethyl derivatives of the nitriles of dichloro-glycollic acid, and of chloro-glyoxylic acid.

Paranitrile $(CCl_3.CN)_3$. *Per-chloro-tri-methyl-cyanidine.* [96°]. *Formation.*—1. Cyanoformic ether, $CN.CO_2Et$, is distilled with PCl_5, and the liquid product, probably $CN.COCl$, is heated in a sealed tube at 160° with PCl_5. The product is distilled with steam and crystallised from alcohol. The yield is 6 per cent. (A. Weddige, *J. pr.* [2] 28, 188; 33, 77).—2. From ordinary tri-chloro-acetonitrile by saturating it with HCl and exposing it, in sealed tubes, to sunlight. In about a year the contents of the tubes solidifies. The solid nitrile is crystallised from alcohol. *Properties.*—Large prisms (from hot alcohol). Sol. alcohol, benzene, ether, CS_2, and chloroform. Hardly sol. water. Volatile with steam. *Reactions.*—1. Decomposed by *alcoholic potash*, thus:

$$(CCl_3.CN)_3 + 3KOH = C_3N_3(OK)_3 + 3CHCl_3,$$

forming chloroform and potassic cyanurate.—2. Boiled with alcoholic *ammonia* it reacts thus:

$$C_3N_3(CCl_3)_3 + NH_3 = HCCl_3 + C_3N_3(CCl_3)_2.NH_2.$$

The latter body forms flat prisms (from alcohol) [166°]. It is sol. alcohol, ether, and benzene, scarcely sol. water. It is not a base.—3. When heated with alcoholic NH_3 in sealed tubes at 110° tri-chloro-acetic paranitrile reacts thus:

$$C_3N_3(CCl_3)_3\ \ 2NH_3 = 2CHCl_3 + C_3N_3(CCl_3)(NH_2)_2$$

The diamide crystallises from alcohol either in long pyramids containing alcohol or in short six-sided prisms without alcohol of crystallisation. It melts at [236°]. It is sl. sol. ether and benzene, hardly sol. cold water. It forms a salt, $C_3N_3(CCl_3)(NH_2)_2HCl\,2aq.$, crystallising in pearly plates. This salt is decomposed by boiling water. Boiled with NH_3Aq it forms ammeline, or an isomeride $C_3N_3(OH)(NH_2)_2$.—4. Heated with NH_3Aq at 120°, or alcoholic NH_3 at 170° it forms $C_3N_3(OH)(NH_2)_2$ *v.* AMMELINE.—5. Aqueous or alcoholic *methylamine* at 20° forms $C_3N_3(CCl_3)_2NHMe$. Small crystals [117°]. V. sol. alcohol, sol. benzene. Is not a base. With alcoholic ammonia at 110° it gives rise to $C_3N_3(CCl_3)(NH_2)(NHMe)$. This body is also got from $C_3N_3(CCl_3)_2(NH_2)$ and alcoholic methylamine. It forms colourless crystals [153°–155°]. 6. Alcoholic methylamine at 110° in a sealed tube forms $C_3N_3(CCl_3)(NHMe)_2$. Small white crystals [207°]. Sol. alcohol and benzene. Forms salts.—7. Aqueous *methylamine* at 120° forms $C_3N_3(OH)(NMeH)_2$. Slender needles. Forms a platino-chloride $(B'HCl)_2PtCl_4$ (Weddige; *v.* also Hofmann, *B.* 18, 2770).

CHLORO-ACETIC ALDEHYDE $CH_2Cl.CHO$. (85°?).

Formation.—1. From vinyl chloride, HClO, and HgO (Glinsky, *Z.* 1867, 678; 1868, 617; 1870, 647).—2. From di-chloro-ether and conc. H_2SO_4 (Jacobsen, *B.* 4, 216).

Preparation.—A mixture of chloro-acetal (1000 g.) and dry oxalic acid (590 g.) is distilled at 100°–150° in an atmosphere of CO_2. The residue consists chiefly of oxalic ether, the distillate contains formic ether, oxalic acid, and chloro-acetic aldehyde. A portion (87°–91°) purified by fractional distillation is obtained in the form of a crystalline hydrate either by use of a freezing mixture or by means of $NaHSO_3$. Water of crystallisation is removed by distillation over $CaCl_2$ or $CuSO_4$. The anhydrous aldehyde is, however, best obtained by distilling its polymeride (Natterer, *M.* 3, 442).

Properties.—Colourless liquid which combines with water, forming a crystalline hydrate, $CH_2Cl.CHO\ \frac{1}{2}aq$ [43°–50°]. The V.D. (1·98) of the hydrate shows that it dissociates. It forms monoclinic crystals. Sol. water, alcohol, and ether; blisters the skin. Reduces ammoniacal $AgNO_3$, forming a mirror.

Reactions.—1. *Oxidised* by HNO_3 to chloro-acetic acid. 2. *Potassium cyanide* gives an oil $(CH_2Cl.CHO)(CH_2Cy.CHO)$ whence HCl forms acetic and chloro-oxy-propionic acids.—3. By *heating* alone or with some H_2SO_4 it is converted into $\alpha\gamma$-di-chloro-crotonic aldehyde.—4. HCl passed into a mixture of chloro-acetic aldehyde and alcohol forms di-chloro-ether.

Combinations.—1. With *alcohol* it forms an alcoholate, $CH_2Cl\,CH(OH)(OEt)$. (c. 94°). Also formed from di-chloro-ether with water (7 vols.) at 120° (Abeljanz, *A.* 1[illegible], 217). Repeated distillation converts it into $C_8H_{16}Cl_2O_3$ (164°).—2. With *acetyl chloride*: $CH_2Cl.CHCl(OAc)$. (c. 147°). Formed also by reducing the corresponding compound of chloral with acetyl chloride by Zn and acetic acid (Curie a. Milliet, *B.* 9, 1611).—3. With *bisulphite of soda*: $C_2H_3ClONaHSO_3\,2aq$: six-sided tables (from water). Separates from alcohol as a powder (containing $\frac{1}{2}aq$). Boiling Na_2CO_3 decomposes it without regenerating the chloro-acetic aldehyde.—4. With *calomel*: $C_2H_3ClOHg_2Cl_2$.

Chloro-acetic paraldehyde $(C_2H_3ClO)_3$. [87°]. (140°) at 10 mm. S.G. 2·77. V.D. 8·25 (calc. 8·31). An amorphous porcelain-like mass into which the aldelhyde slowly changes on keeping (probably when not perfectly pure). It also separates from a solution of the hydrate in conc. H_2SO_4. Trimetric crystals, $a:b:c = 1·51:1:·941$. Insol. water, sl. sol. cold alcohol, v. sol. ether. At 245° it is reconverted into the ordinary modification. Not acted upon by iron and acetic acid, by AgOAc and HOAc, by alcoholic NH_3, by KOHAq at 100°, or by cold NaOEt (Natterer, *M.* 6, 519).

Chloro-acetic orthaldehyde $CH_2Cl.CH(OH)_2$. Contrary to analogy, the hydrate of chloro-acetic aldehyde does not seem to have the above formula, but appears to be $CH_2Cl.CH(OH).O.CH(OH).CH_2Cl$ (*v. supra*). The di-alkylated derivatives of chloro-acetic ortho-aldehyde are called acetals.

Ethyl ether $CH_2Cl.CH(OH)(OEt)$. *Chloro-aldehyde alcoholate.* (93°–95°). Formed by the action of water at 120° on dichlorinated ethyl oxide $CH_2Cl.CHCl.OEt$. On distillation it forms an anhydride, $(CH_2Cl.CH.OEt)_2O$, (163°–165°), which is split up by conc. H_2SO_4 into chloro-acetic aldehyde and alcohol. This body is also formed from di-chloro-di-ethyl ether and potash.

Acetyl derivative of the ethyl ether $CH_2Cl.CH(OEt)(OAc)$. (170°). From di-chloro-ethyl ether and silver acetate (Bauer, *A.* 134, 176).

Methyl ethyl ether $CH_2Cl.CH(OEt)(OMe)$. (137°). S.G. $\frac{14}{}$ 1·056. From di-chloro-ethyl ether and sodium methylate (Lieben, *A.* 146, 202).

Di-ethyl ether $CH_2Cl.CH(OEt)_2$. *Chloro-acetal.* (157°). S.G. $\frac{0}{}$ 1·042. V.D. 5·38 (calc. 5·29). *Formation.*—1. When chlorine is passed into dilute alcohol (80 p.c.) for some time, on adding water a heavy oil separates. By fractional distillation this is found to consist chiefly of aldehyde, chloro-acetal, and di-chloro-acetal. The fraction 120°–170° is digested for several days with aqueous KOH and rectified (Lieben, *A. Ch.* [3] 56, 313; Krey, *Jena. Zeit.* 10, 84).—2. From di-chloro-ethyl ether $CH_2Cl.CHCl.OEt$ and NaOEt (Lieben, *A.* 146, 193; Natterer, *M.* 3, 444); or by long boiling with alcohol (Paterno a. Mazzara, *B.* 6, 1202).—3. From di-chloro-ethylene and alcoholic NaOEt at 40°–50° (Klien, *J.* 1876, 336).—4. By warming chloro-acetic aldehyde with alcohol (Natterer, *M.* 5, 497). *Properties.*—Aromatic liquid, insol. water, sol. alcohol. Not attacked by aqueous KOH. Does not pp. $AgNO_3$.—*Reactions.*—1. NaOEt at 150° gives $CH_2(OEt).CH(OEt)_2$.—2. *Sodium* forms $CH_2:CH.OEt$ (Wislicenus, *A.* 192, 106).—3. Boiling with powdered *zinc* gives EtCl and alcohol.—4. Heating with *oxalic acid* gives chloro-acetic ldehyde and oxalic ether. HOAc acts similarly.—5. HCl gives di-chloro-ethyl ether $H\_Cl.CHCl.OEt$.—6. Poured upon *bleaching-powder*, no action ensues, but upon heating over a water bath a reaction takes place and a greensh liquid collects in the receiver. This distillate presently decomposes, the products being chlorne, HCl, undecomposed chloro-acetal, di- and ri-chloro-acetals, chloroform, and an aldehyde Goldberg, *J. pr.* 132, 109).

D -chloro-acetic aldehyde, $CHCl_2.CHO$. Mol. w. 113. (89°).

Formation.—1. By distilling di-chloro-acetal ith H_2SO_4 (Grimaux a. Adam, *Bl.* 34, 29; Paerno, *Z.* 1868, 667).—2. By boiling $CCl_2:CH.OMe$ ith dilute H_2SO_4 (Denaro, *G.* 14, 119).—3. By istilling its hydrate obtained by chlorination of chloro-acetic paraldehyde (*v. di-chloro-acetic ortho-aldehyde*) with H_2SO_4.

Properties.—Liquid, which, in presence of some HCl, gradually changes to an amorphous solid variety, which at 120° returns to the liquid form.

Reactions.—1. *Oxidised* by HNO_3 to dichloro-acetic acid.—2. PCl_5 forms $CHCl_2.CHCl_2$ (147°) (Paterno, *Z.* 1868, 667).

Di-chloro-acetic paraldehyde $(CHCl_2.CHO)_x$. [130°]. S.G. 1·69. From di-chloro-acetic aldehyde (or di-chloro-acetal) in presence of H_2SO_4 in the cold (Jacobsen, *B.* 8, 87; *cf.* Krey, *J.* 1876, 475). Hexagonal pyramids (from alcohol). V. sol. hot alcohol. May be sublimed, but at 240° in a sealed tube, or with conc. H_2SO_4 at 130°, it changes to liquid di-chloro-acetic aldehyde.

Amorphous polymeride $(CHCl_2.CHO)_n$. Formed spontaneously by the polymerisation of (impure ?) di-chloro-acetic aldehyde (Friedrich, *A.* 206, 252). Paraffin-like mass, insol. water, m. sol. ether, sl. sol. hot alcohol. Does not melt below 200°. Converted by heat into ordinary di-chloro-acetic aldehyde.

Di-chloro-acetic orthaldehyde $CHCl_2.CH(OH)_2$. *Di-chloro-acetic aldehyde hydrate.* [43°] (F.); [57°] (Denaro, *G.* 14, 120) (c. 120°). Formed as a by-product in the preparation of tri-chloro-butyric aldehyde by the action of chlorine upon paraldehyde (Friedrich, *A.* 206, 251). Micaceous scales. V. sol. water and ether. Oxidised by HNO_3 to di-chloro-acetic acid. Conc. H_2SO_4 converts it into di-chloro-acetic aldehyde and its amorphous polymeride.

Di-ethyl ether $CHCl_2.CH(OEt)_2$. *Di-chloro-acetal.* Mol. w. 187. (184°). V.D. 6·45 (calc. 6·44). S.G. $\frac{14}{}$ 1·138. Formed by chlorinating alcohol (*v. supra*) or acetal (Lieben, *A.* 104, 114; Pinner, *B.* 5, 148; Krey, *J.* 1876, 474). Also from tri-chloro-ethyl ether $CHCl_2.CHCl.OEt$ and NaOEt (Jacobsen, *B.* 4, 217).

Reactions.—1. *Zinc-ethyl* at 140° gives propylene, ethylene, and other gases, leaving ether: (Paterno, *C. R.* 77, 458).—2. PCl_5 gives tri-chloro-ethyl ether $CHCl_2.CHCl.OEt$.—3. NaOEt gives the tetra-ethyl derivative of ortho-glyoxal $CH(OEt)_2.CH(OEt)_2$ (Pinner, *B.* 5, 151).—4. Conc. H_2SO_4 or HClAq converts it into di-chloro-acetic aldehyde. Fuming H_2SO_4 forms a crystalline compound $C_6H_5Cl_5O_3$ [129°] (Grabowsky, *B.* 6, 1071). According to Pinner (*A.* 179, 34) di-chloro-acetal is *not* converted into di-chloro-acetic aldehyde by H_2SO_4, and does *not* give di-chloro-acetic acid on oxidation by HNO_3.

Tri-chloro-acetic aldehyde *v.* Chloral.

Tri-chloro-acetic orthaldehyde *v.* Chloral *hydrate.*

Di-ethyl ether $CCl_3.CH(OEt)_2$ (*v.* p. 4).

An *isomeride*, possibly having the constitution $CHCl_2.CCl(OEt)_2$, [72°] (P.); [83°] (K.), (230°), is formed as a secondary product in the preparation of di-chloro-acetal by the chlorination of 80 p.c. alcohol (Paterno, *C. R.* 67, 765; Lieben, *A.* 104, 114; Kley, *J.* 1876, 475). Needles (from ether). Volatile with steam. It is doubtful whether it yields chloral on treatment with H_2SO_4; such a reaction would indicate the same formula as that ascribed to the liquid isomeride (*v.* p. 4).

TRI-CHLORO-ACETIC ANHYDRIDE *v. Anhydride* of *Tri*-CHLORO-ACETIC ACID.

CHLORO-ACETO-ACETIC ETHER $C_6H_9ClO_3$ *i.e.* $CH_3.CO.CHCl.CO_2Et$ or $CH_2Cl.CO.CH_2.CO_2Et$. (194°). S.G. ^{14} 1·19. Formed, together with SO_2 and HCl, by the action of SO_2Cl_2 (1 mol.) or of Cl upon aceto-acetic ether (1 mol.) (Allihn, *B.* 11, 568; Merves, *A.* 245, 58). Liquid. Alcoholic KOH liberates chloro-acetic acid. (α)-Naphthylamine forms $C_{16}H_{16}NO_2Cl$ [75°] (Bender, *B.* 20, 2747). Fuming HNO_3 forms chloro-nitroso-aceto-acetic ether $CH_3.CO.CCl(NO).CO_2Et$ (?) (Pröpper, *A.* 222, 48). Phenyl-hydrazine in ethereal solution forms $C_{12}H_{14}N_2O_2$ [51°], which is probably $CH_3.C(N_2Ph):CH.CO_2Et$, which may be reduced to oxy-phenyl-methyl-pyrazole.

Metallic compounds.—Formed as precipitates by shaking the ether with ammoniacal solutions of the metallic salts.—$(C_6H_8O_3Cl)_2Cu$: green leaflets.—$(C_6H_8O_3Cl)_2Mg$: white needles.—$(C_6H_8O_3Cl)_2Ni$: light-green powder.—$(C_6H_8O_3Cl)_2Co$: light-red powder (Hensgen, *B.* 12, 1300).—$C_6H_8O_3ClNa$: crystalline powder, v. sol. alcohol (Conrad a. Guthzeit, *B.* 16, 1554).

Di-chloro-aceto-acetic ether $CH_3.CO.CCl_2.CO_2Et$ or $CHCl_2.CO.CH_2.CO_2Et$. (206°). S.G. $\frac{16}{17\cdot5}$ 1·293. Formed, together with SO_2 and HCl, by the action of SO_2Cl_2 (2 mols.) on aceto-acetic ether (1 mol.) (Allihn, *B.* 11, 567). Formed also by chlorinating aceto-acetic ether (Conrad, *A.* 186, 232). Liquid. Decomposed by dilute HCl at 180° into CO_2, alcohol, and di-chloro-acetone. KOH gives di-chloro-acetic and acetic acids. Decomposed by KCN into HCN, acetic ether, and potassium di-chloro-acetate (James, *A.* 240, 65; *C. J.* 51, 287). Di-chloro-aceto-acetic acid does not form metallic salts, nor does it react with aldehydes (difference from di-bromo-aceto-acetic ether).

Tri-chloro-aceto-acetic ether $C_6H_7Cl_3O_3$ (223°). From aceto-acetic ether and Cl in daylight (Merves, *A.* 245, 70). With NaOEt it gives di-chloro-acetic ether.

CHLORO-ACETOL *v.* DI-CHLORO-PROPANE.

CHLORO-ACETONE C_3H_5ClO *i.e.* $CH_3.CO.CH_2Cl$. (118°). S.G. ^{13} 1·158 (Cloez).

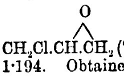
Formation.—1. By electrolysis of a mixture of acetone and HCl (Riche, *C. R.* 49, 176).—2. From acetone and HClO (Mulder, *B.* 5, 1007).—3. By passing chlorine (1 mol.) into well-cooled acetone (M.).—4. By dissolving di-chloro-propylene $CH_2Cl.CCl:CH_2$ in conc. H_2SO_4 and distilling the product with water (Henry, *B.* 5, 190, 965).—5. From bromo- or chloro-propylene by the action of hypochlorous acid and HgO (Linnemann, *A.* 138, 122).—6. By oxidation of propylene chlorhydrin (from propylene glycol) with $K_2Cr_2O_7$ and H_2SO_4 (Morley a. Green, *B.* 18, 24).

Preparation.—By passing chlorine into acetone at 15° (Cloez, *A. Ch.* [6] 9, 145).

Properties.—Pungent oil; v. sl. sol. water. According to Cloez it is not pungent when quite pure, and the pungency can be removed by washing with very weak alkali. Volatile with steam. It gives a splendid crimson colour with solid KOH, or a strong aqueous solution of KOH. With $NaHSO_3$ it forms crystalline $C_3H_5Cl(OH)(SO_3Na)$ (Barbaglia, *B.* 6, 821).

Reactions.—1. Zn and HCl reduce it to acetone.—2. Moist Ag_2O *oxidises* it to glycollic, acetic, and formic acids.—3. K_2SO_3 gives $CH_3.CO.CH_2.SO_3K$.—4. Potassium acetate forms $CH_3.CO.CH_2.OAc$.—5. Alcoholic KCN produces $CH_3.CO.CH_2CN$.—6. Fuming HNO_3 forms crystalline nitroso-chloro-acetone $C_3H_4ClNO_2$ [110°] (Glutz, *J. pr.* [2] 1, 141).—7. Alcoholic *ammonium sulphocyanide* gives the crystalline sulphocyanide [114°] of imido-propyl sulphocyanide $CH_3.C(NH).CH_2.SCN$ [42°] (Norton a. Tcherniak, *Bl.* [2] 33, 203).—8. *Barium sulphocyanide* forms $CH_3.CO.CH_2SCN$ which is an oil (Tcherniak a. Hellon, *B.* 16, 349).—9. *Bromine* at 100° forms chloro-tri-bromo-acetone.—10. *Ammonia* forms a compound ($CH_3.CO.CH_2NH_2$?) which gives methylamine on distillation with potash (Cloez). 11. Chloro-acetone (2 mols.) added to an aqueous solution of (1, 3, 4)-tolylene-diamine at 60° forms methyl-toluquinoxaline  $C_6H_3Me<\begin{matrix}N:CH\\|\\N:CMe\end{matrix}$ [54°] (Hinsberg, *A.* 237, 368).—12. Alcoholic KOBz forms $CH_3.CO.CH_2.OBz$ (245° at 380mm.) (van Romburgh, *R. T. C.* 1, 53).—13. Conc. HCNAq forms the cyanhydrin $CH_3.C(OH)(CN).CH_2Cl$ which is the nitrile of chloro-oxy-isobutyric acid (chloro-acetonic acid) (C. Bischoff, *B.* 5, 865).

Isomeride of chloro-acetone C_3H_5ClO *i.e.*



$CH_2Cl.\overset{\overset{O}{\wedge}}{CH.CH_2}$ (?) *Epichlorhydrin* (119°). S.G. ^{11} 1·194. Obtained from glycerin dichlorhydrin $CH_2Cl.CH(OH).CH_2Cl$ and warm conc. KOH (Prevost, *P.* [2] 12, 160). Liquid. Combines with HCl, water, and HOAc forming derivatives of di-chlorhydrin. With alcoholic NH_3 it forms $C_3H_{12}ClNO_2$ (Cloez, *A. Ch.* [6] 9, 145).

u-**Di-chloro-acetone** $CHCl_2.CO.CH_3$. Mol. w. 127. (120°). S.G. ^{15} 1·234.

Formation.—By heating di-chloro-aceto-acetic ether with water at 180° (Conrad, *A.* 186, 235) or by boiling it with HClAq for 5 hours (V. Meyer, *B.* 15, 1165).

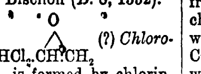
Preparation.—By the prolonged action of chlorine upon well-cooled acetone (Fittig, *A.* 110, 40; 133, 112; Mulder, *B.* 5, 1007; Cloez, *A. Ch.* [6] 9, 145).

Properties.—Pungent liquid, sl. sol. water. Combines with bisulphite of soda forming $C_3H_4Cl_2(OH)(SO_3Na)3aq$.

Reactions.—1. *Ammonia* forms the compound $CH_3.CO.CHCl(NH_2)$ which yields methylamine when distilled with potash.—2. PCl_5 gives tetra-chloro-propylene and a small quantity of penta-chloro-propylene.—3. KHS gives a yellow viscid body C_3H_4SO, the alcoholic solution of which gives with lead acetate a red pp. $C_3H_4SOPbOaq$ (Mulder, *B.* 5, 1008).—4. *Hydroxylamine* forms acetoximic acid $CH_3.C(NOH).CH(NOH)$ (*v.* vol. i. p. 38).—5. *Water* at 200° gives lactic acid (Linnemann a. Zotta, *A.* 159, 248).—6. *Potash* splits it up into acetic and formic acids.—7. HCN gives the cyanhydrin $CH_3.C(OH)(CN).CHCl_2$ or the nitrile of di-chloro-oxy-isobutyric acid (Bischoff, *B.* 8, 1333).—8. Aqueous KCN gives crystalline tufts of $(C_3H_4Cl_2O)_2HCN$ (Glutz a. Fischer, *J. pr.* [2] 4, 52).

Isomeride of di-chloro-acetone $C_3H_4Cl_2O$. [44°]. (c. 168°). The entire product of the action of chlorine on cooled acetone has the composition of di-chloro-acetone, although it boils between 117° and 170°. This appears to be due to the presence of this crystalline isomeride. It only differs from *s*-di-chloro-acetone, derived from dichlorhydrin, in yielding with bromine a di-chloro-di-bromo-acetone identical with that obtained from *u*-di-chloro-acetone, and not with that obtained from the said *s*-di-chloro-acetone (Barbaglia, *B.* 7, 468; Cloez). This compound could not be obtained by Bischoff (*B.* 8, 1332).

Another isomeride



$\overset{O}{\widehat{CHCl_2.CH.CH_2}}$

(?) *Chloro-epichlorhydrin* (?) (170°), is formed by chlorinating epichlorhydrin (Cloez, *A. Ch.* [6] 9, 145). With NH_3 it forms unstable $C_6H_9Cl_2NO_2$.

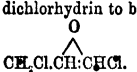
***s*-Di-chloro-acetone** $CH_2Cl.CO.CH_2Cl$. [44°]. (173° cor.). V.D. 63·2.

Formation.—1. By the oxidation of the corresponding dichlorhydrin of glycerin $CH_2Cl.CH(OH).CH_2Cl$ with $K_2Cr_2O_7$ and H_2SO_4. Purified by means of its crystalline compound with $NaHSO_3$ which is subsequently decomposed by Na_2CO_3. The yield is very small (Glutz a. Fischer, *J. pr.* [2] 4, 52; Hörmann, *B.* 13, 1707; Markownikoff, *A.* 208, 349).—2. By the union of HClO with *a*-chloro-allyl chloride (di-chloro-propylene) $CH_2Cl.CCl{:}CH_2$ and HClO (Henry, *C. R.* 94, 1428).—3. From *s*-di-iodo-acetone and AgCl (Voelker, *A.* 192, 89).

Properties.—Long needles or trimetric tables. Extremely pungent; blisters the skin. M. sol. water, v. sol. alcohol and ether. With bisulphite of soda it forms long four-sided prisms of $C_3H_4Cl_2(OH)(SO_3Na)$ 3aq.

Reactions.—1. KI forms di-iodo-acetone [61°].—2. Dry KCN added to its ethereal solution forms crystalline tetra-chloro-di-acetone cyanhydrin $(C_6H_8Cl_4O_2)HCN$ which differs from the isomeric body obtained from *u*-di-chloro-acetone in being insol. water (G. a. F.).—3. HCN forms $(CH_2Cl)_2C(OH)CN$, the nitrile of di-chloro-oxy-isobutyric (di-chloro-acetonic) acid.—4. *Oxidised* by $K_2Cr_2O_7$ and H_2SO_4 to chloro-acetic acid.

According to Cloez (*A. Ch.* [6] 9, 145) successive treatment with bromine and $HgCl_2$ gives tetra-chloro-acetone, but the tetra-chloro-acetone prepared in this way from the di-chloro-acetone obtained from dichlorhydrin is different from that obtained from di-iodo-acetone. They also give different penta-chloro-acetones when treated with chlorine in sunlight. Cloez considers the derivative from dichlorhydrin to be a pseudo-di-chloro-acetone



$\overset{O}{\widehat{CH_2Cl.CH{:}CHCl}}$.

It does not combine with HOAc, but reacts violently with HCl, although the product, exposed over H_2SO_4, is re-converted into ψ-di-chloro-acetone.

Tri-chloro-acetone $CCl_3.CO.CH_3$. (180°) (Combes).

Formation.—Obtained in an impure state by passing chlorine into acetone that is not kept cool, especially if the chlorine be somewhat moist, or the acetone be mixed with methyl alcohol (crude wood spirit) (Bischoff, *B.* 8, 1331). The crude product of the oxidation of isobutyl alcohol with chromic mixture may also be used (Krämer, *B.* 7, 252).

Preparation.—1. By passing chlorine into an aqueous solution of sodium citraconate at 100° (Gottlieb a. Morawsky, *J. pr.* [2] 12, 369).—2. By the action of NaOH (1 mol.) upon hexa-*ω*-chloro-methylene di-methyl diketone (hexa-chloro-acetyl-acetone) $(CCl_3.CO)_2CH_2$ (Combes, *A. Ch.* [6] 12, 239).

Properties.—Liquid, heavier than water, with fragrant odour. Converted by ammonia into chloroform and acetamide. Does not unite with $NaHSO_3$; but with HCN it forms $CCl_3.CMe(OH)CN$ (Bischoff). It unites readily with water, forming a hydrate $C_3H_3Cl_3O$ 2aq [44°] crystallising in four-sided prisms, which is resolved by distillation or by dry HCl into its constituents. The product of the chlorination of acetone boils at 172°, and has S.G. 1·418. According to Cloez it is a mixture; for it solidifies incompletely on cooling, when it deposits needles [c. −5°]. With aniline and KOH it gives phenyl-carbamine, showing the presence of $CCl_3.CO.CH_3$. Successive treatment with ammonia and KOH gives di-chloro-methyl-amine, indicating the presence of $CHCl_2.CO.CH_2Cl$.

Tri-chloro-acetone $CHCl_2.CO.CH_2Cl$. (172°). From *u*-di-chloro-acetone by treating with bromine and heating the resulting $CHCl_2.CO.CH_2Br$ with $HgCl_2$ in presence of alcohol (Cloez). Gives no chloroform with ammonia, nor phenyl-carbamine with aniline and KOH.

***u*-Tetra-chloro-acetone** $CH_2Cl.CO.CCl_3$. (181°). S.G. ^{17} 1·482. Formed by saturating acetone containing methyl alcohol or wood spirit with chlorine in daylight, the temperature being allowed to rise (Bouis, *A. Ch.* [3] 21, 111). The fraction boiling at 160°–180° is exposed to a low temperature in contact with water, whereupon the hydrate of tri-chloro-acetone crystallises out first, then a compound of this with tetra-chloro-acetone hydrate $(C_3H_3Cl_3O)(C_3H_2Cl_4O)$ 6aq [32°], and finally large prisms of the hydrate of tetra-chloro-acetone $C_3H_2Cl_4O$ 4aq [39°] (c. 179°), which may be resolved by dry HCl into tetra-chloro-acetone and water.

Properties.—Colourless hygroscopic liquid, sol. water, with pungent odour. Readily volatile with steam. Turned brown by air and light. Partially decomposed by distillation. With aniline and KOH it yields phenyl carbamine. Aqueous ammonia at a low temperature forms chloroform and chloro-acetamide.

***s*-Tetra-chloro-acetone** $CHCl_2.CO.CHCl_2$. (180°). S.G. ^{17} 1·48. Formed by treating *u*-di-chloro-acetone, or the *s*-di-chloro-acetone derived from *s*-di-iodo-acetone, with bromine and decomposing the resulting $CHCl_2.CO.CHBr_2$ with $HgCl_2$ in alcoholic solution at 100°. Purified by conversion into its crystalline hydrate [48°] and subsequent dehydration by dry HCl (Cloez). This tetra-chloro-acetone does not give the chloroform and carbamine reactions. The di-chloro-di-bromo-derivative obtained by the action of bromine on dichlorhydrin yields with $HgCl_2$ an oil which is not attacked by ammonia. The product of the oxidation of dichlorhydrin gives with bromine CHClBr.CO.CHClBr (Markownikoff), whence $HgCl_2$ gives a fuming liquid (180°); this liquid does not combine with $NaHSO_3$, but yields with ammonia di-chloro-acetamide, and with aniline di-chloro-acetanilide. Cloez con-

siders that it is isomeric, but not identical with *s*-tetra-chloro-acetone; thus it might be

$\mathrm{CH_2Cl.}\overset{\mathrm{O}}{\overbrace{\mathrm{CH.CCl_2}}}.$

Penta-chloro-acetone $CCl_3.CO.CHCl_2$. (192°). S.G. $\frac{14}{4}$ 1·576. S. 15.

Formation.— 1. By passing chlorine into a strong solution of sodium citraconate (Plantamour, *Gm.* 11, 440).—2. By the action of HCl and $KClO_3$ on various organic compounds, *e.g.* quinic, citric, gallic, and salicylic acids, pyrogallol, quinone, indigo, tyrosine, and muscular flesh (Städeler, *A.* 111, 277).—3. By the action of chlorine in sunlight upon commercial acetone or on di-chloro-acetone (Cloez, sen., *A.* 111, 180; Cloez, jun., *Bl.* [2] 39, 637). Pure acetone gives only di-chloro-acetone when chlorinated at 100° in sunlight (Fittig).

Preparation.—A solution of citric acid in 1½ pts. water is allowed to fall drop by drop down a tube packed with pumice heated to 100°, up which a current of dry chlorine is passing (Cloez, jun., *A. Ch.* [6] 9, 145).

Properties.—Colourless liquid, smelling (after exposure to air) like chloral. With water at 4° it forms a crystalline hydrate $C_3HCl_5O\,4aq$ [15°], which, on fusion, separates into water and penta-chloro-acetone. Penta-chloro-acetone separates completely from its aqueous solution at 60°. Penta-chloro-acetone dissolves a little water, but on warming this separates as globules.

Reactions.—1. *Ammonia* gives chloroform and di-chloro-acetamide [95°] (235°).—2. *Aniline* and KOH give phenyl-carbamine.—3. KOH gives di-chloro-acetic acid, KCl, and K_2CO_3.

Isomeride of penta-chloro-acetone

$\mathrm{CCl_3.}\overset{\mathrm{O}}{\overbrace{\mathrm{CH.CCl_2}}}$(?). *Tetra-chloro-epichlorhydrin.* (185°). S.G. $\frac{0}{4}$ 1·617. By the action of chlorine in sunlight on the *s*-di-chloro-acetone from dichlorhydrin (Cloez, jun., *Bl.* [2] 39, 639). Pungent liquid. With ammonia it gives tri-chloro-acetamide [139°] (235°–240°) but no chloroform.

Another isomeride of penta-chloro-acetone

$\mathrm{CHCl_2.}\overset{\mathrm{O}}{\overbrace{\mathrm{CCl.CCl_2}}}$(?). (178°). From di chloro-propylene oxide and chlorine (Cloez, jun., *A. Ch.* [6] 9, 145). Fuming liquid. With ammonia it gives di-chloro-acetamide, but no chloroform.

Hexa-chloro-acetone $CCl_3.CO.CCl_3$. [−2°]. (203°). S.G. ^{12} 1·744. V.D. 9·62. Formed by saturating a conc. aqueous solution of citric acid with chlorine in sunshine (Plantamour, *B. J.* 26, 428). The yield is 25 p.c. of the weight of citric acid. Formed also by the action of chlorine on (commercial) acetone in sunlight. On distilling the product a considerable quantity of hexa-chloro-benzene is usually formed.

Properties.—Limpid liquid, which has a feeble odour in the cold, but becomes very pungent when warmed. Solidifies when cooled in large plates. Sl. sol. water. Forms a crystalline hydrate C_3Cl_6O aq [15°] almost insol. water.

Reactions.—1. With aqueous *ammonia* it forms chloroform and tri-chloro-acetamide.—2. *Aniline* forms chloroform and tri-chloro-acetanilide.—3. *Water* at 120° splits it up into chloroform and tri-chloro-acetic acid.—4. *Potash* gives CO_2 and tri-chloro-acetic acid.—5. With *o-toluidine* it forms tri-chloro-acetyl *o*-toluidine $C_6H_4Me.NH.CO.CCl_3$ [67°]; with *p-toluidine* it forms the isomeric body [80°].—6. *Diethylamine* gives $NEt_2.CO.CCl_3$ [90°].—7. *Allylamine* forms $NHC_3H_5.CO.CCl_3$ [45°].—8. *Ethylene-diamine* gives $NH_2.C_2H_4.CO.CCl_3$ [200°].—9. *Urea* (1 mol.) at 150° forms $CO(NH.CO.CCl_3)_2$.

Isomeride of hexa-chloro-acetone

$\mathrm{CCl_3.}\overset{\mathrm{O}}{\overbrace{\mathrm{CCl.CCl_2}}}$(?) (c. 205°). This substance appears to be formed, together with hexa-chloro-benzene, by the action of chlorine on epichlorhydrin in sunlight (Cloez, jun.).

CHLORO-ACETONIC ACID *v.* CHLORO-OXY-ISOBUTYRIC ACID.

CHLORO-ACETONITRILE *v.* *Nitrile of* CHLORO-ACETIC ACID.

ω-CHLORO-ACETOPHENONE $C_6H_5.CO.CH_2Cl$. *Phenacyl chloride. Phenyl chloro-methyl ketone.* [59°]. (245°). Formed, together with di- and tri-chloro-acetophenone, by passing chlorine into boiling acetophenone. The fraction (240°–250°) solidifies on cooling, and is recrystallised from dilute alcohol (Gräbe, *B.* 4, 35; Städel, *B.* 10, 1830; Gautier, *C. R.* 102, 1248). Colourless trimetric plates; *a*:*b*:*c* = ·9957:1:·2135 (Friedlander); v. e. sol. alcohol and ether, insol. water. Its vapour is pungent.

Reactions.—1. KOAc forms the acetyl derivative of ω-oxy-acetophenone, $C_6H_5.CO.CH_2OAc$. 2. PCl_5 forms di-chloro-styrene $C_6H_5.CCl:CHCl$.—3. *Chromic acid* oxidises it to benzoic acid.—4. *Ammonia* passed into its ethereal solution forms two isomerides $C_{16}H_{13}ClO_2$ [117°] and [155°]. Boiling aqueous ammonia forms (*a*)-phenyl-amphinitrile or isoindole $C_{16}H_{14}N_2$ [195°], which crystallises from alcohol in blue monoclinic needles (V. Meyer a. Treadwell, *B.* 16, 342).—5. (1, 3, 4)-Tolylene-diamine gives phenyl-toluquinoxaline $C_6H_3Me\left\langle\begin{matrix}N:CH\\N:CPh\end{matrix}\right\rangle$ [135°] (Hinsberg, *A.* 237, 370).

***p*-Chloro-acetophenone** [4:1]$C_6H_4Cl.CO.CH_3$. *Chloro-phenyl methyl ketone.* [20°]. (231°). S.G. ^{20} 1·19. From chloro-benzene, acetyl chloride, and Al_2Cl_6 (Gautier, *Bl.* [2] 43, 602). V. sl. sol. water, miscible with alcohol and ether. $KMnO_4$ oxidises it to *p*-chloro-benzoic acid.

Di-ω-chloro-acetophenone $C_6H_5.CO.CHCl_2$. (248°). S.G. ^{15} 1·338. From di-chloro-acetyl chloride, benzene, and Al_2Cl_6 (Gautier, *C. R.* 103, 812).

Tri-ω-chloro-acetophenone $C_6H_5.CO.CCl_3$. (249°). S.G. ^{16} 1·427. From tri-chloro-acetyl chloride (60 g.), benzene (100 g.), and Al_2Cl_6 (Gautier, *C. R.* 103, 812). Oil; slowly oxidised by $KMnO_4$ to benzoic acid.

TRI-ω-CHLORO-ACETOPHENONE *o*-CARBOXYLIC ACID $CCl_3.CO.C_6H_4.CO_2H$. [144°]. Formed by passing chlorine into a hot solution of phthalyl-acetic acid in diluted HOAc (Michael a. Gabriel, *B.* 10, 1556). Decomposed by alkalis into chloroform and phthalic acid.

CHLORO-ACETOTHIENONE *v.* THIËNYL CHLORO-METHYL KETONE.

CHLORO-ACETOXIM $(CH_3)_2C:NOCl$. *Acetchloroxim.* (134° uncor.); when quickly heated it explodes with violence. V.D. 4·1 (for 3·7). Obtained by adding a solution of hypochlorous acid to an aqueous solution of acetoxim at 0°; the liquid that separates is washed with water, and dried over $CaCl_2$. Colourless mobile liquid of pleasant odour, which solidifies in a freezing-mixture of solid CO_2 and ether, to colourless prisms. V. sol. alcohol and ether, v. sl. sol. water. Warmed with HCl or HI it sets free the halogens (Möhlau a. Hoffmann, *B.* 20, 1505).

TRI-CHLORO-β-ACETYL-ACRYLIC ACID *v.* TRI-CHLORO-PHENOMALIC ACID.

TRI-CHLORO-ACETYL-BENZOIC ACID *v.* TRI-CHLORO-ACETOPHENONE CARBOXYLIC ACID.

CHLORO-ACETYL BROMIDE $CH_2Cl.CO.Br$. (127°) (W.); (134°) (G.). S.G. ^{0} 1·913. Prepared by adding bromine (160 g.) to chloro-acetic acid (94 g.) and red phosphorus (15 g.) (De Wilde, *A.* 130, 372; 132, 173; Gal, *A.* 132, 180). Fuming liquid. With water it forms HBr and chloro-acetic acid; alcohol gives EtBr and chloro-acetic ether.

Tri-chloro-acetyl bromide $CCl_3.CO.Br$. (140°) (H.); (143°) (G.). S.G. $\frac{15}{15}$ 1·900. From PBr_3 (2 mol.) and tri-chloro-acetic acid (3 mol.). 300 grms. of the acid give 200 grms. bromide (Hofferichter, *J. pr.* 128, 196; Gal, *C. R.* 76, 1019; *Bl.* [2] 20, 11). Water decomposes it into HBr and tri-chloro-acetic acid; alcohol gives EtBr and tri-chloro-acetic ether.

CHLORO-ACETYL CHLORIDE $CH_2Cl.CO.Cl$. Mol. w. 113. (107°). S.G. ^{0} 1·495. Formed by the action of chlorine on acetyl chloride in sunlight (Wurtz, *A.* 102, 93); or, together with di-chloro-acetyl chloride by boiling acetyl chloride with PCl_5 (Michael, *J. pr.* [2] 35, 95). Formed also by treating chloro-acetic acid with PCl_3 (De Wilde, *A.* 130, 372). Liquid, converted by water into HCl and chloro-acetic acid; and by dry ammonia into chloro-acetamide.

Reactions.—1. Successive treatment with *zinc methyl* and water forms methyl-isopropyl-carbinol (Bogomoletz, *Bl.* [2] 34, 330).—2. With *o-amido-phenol* it forms $C_6H_4(OH).NH.CO.CH_2Cl$ [136°] (Aschan, *B.* 20, 1523). It reacts similarly with other amido-compounds.—3. *Phosphuretted hydrogen* forms chloro-acetyl-phosphide $CH_2Cl.CO.PH_2$, a white powder slowly decomposed by water into PH_3 and chloro-acetic acid (Steiner, *B.* 8, 1178).

Di-chloro-acetyl chloride $CHCl_2.CO.Cl$. Mol. w. 147½. (108°). Formed by the action of PCl_5 on di-chloro-acetic acid (Otto a. Beckurts, *B.* 14, 1618); or, together with the preceding, by boiling acetyl chloride with PCl_5 (M.). Pungent, fuming liquid: decomposed at once by water. Successive treatment with $ZnMe_2$ and water forms (6 p.c. of) di-methyl-propyl-carbinol (B.).

Tri-chloro-acetyl chloride $CCl_3.CO.Cl$. (117·9°) (Thorpe, *C. J.* 37, 189). S.G. $\frac{0}{4}$ 1·6564. C.E. (0°–10°) ·001095; (0°–100°) ·0012013. S.V. 125·51.

Formation.—1. From PCl_3 and $CCl_3.CO_2H$ (Gal, *C. R.* 76, 1019). The yield is very small. 2. By the protracted action of chlorine on ether, the operation being conducted towards the end in sunlight (Malaguti, *A. Ch.* [3] 16, 5). Also by the distillation of penta-chloro-ethyl ether $(C_2Cl_5)_2O$, or of perchlorinated acetic ether $CCl_3.CO_2C_2Cl_5$.—3. Together with SO_2 from C_2Cl_4 and SO_3 at 150° (Prudhomme, *C. R.* 70, 1137). Also from C_2Cl_6 and SO_3.

Properties.—Liquid; decomposed by water into HCl and tri-chloro-acetic acid; alcoho gives tri-chloro-acetic ether.

Reactions.—1. *Zinc methide* followed by wate gives the heptyl alcohol $CMe_3.CMe_2OH$ (B.).—2 PH_3 gives $CCl_3.CO.PH_2$ (Steiner, *B.* 8, 1178 Cloez, *A. Ch.* [3] 17, 309).—3. *Tri-chloro-aceti acid* forms the anhydride $(CCl_3.CO)_2O$ (Anschütz *B.* 10, 1881).

TRI-CHLORO-ACETYL CYANIDE $CCl_3.CO.CN$. *Tri-chloro-pyruvonitrile.* (118° (H.); (122°) (C. a. A.). S.G. ^{15} 1·559.

Preparation.—1. By adding AgCy slowly t cooled tri-chloro-acetyl bromide; the reactio being finished by heating on a water-bath (Hofferichter, *J. pr.* 128, 200).—2. By boilin tri-chloro-acetyl bromide with mercurous cyanide (Claisen a. Antweiler, *B.* 13, 1935).

Properties.—Pungent, hygroscopic liquid smelling of prussic acid. Exposed to air it first becomes crystalline (forming a hydrate?) then deliquesces.

Reactions.—1. *Water* decomposes it into tri-chloro-acetic acid and prussic acid.—2. HCl (S.G. 1·16) at 50° converts it into tri-chloro-pyruvic acid $CCl_3.CO.CO_2H$.

Polymeride $(CCl_3.CO.CN)_x$. [140°]. From AgCy and tri-chloro-acetyl bromide at 150° (H.). Dimetric tables (from ether-alcohol); insol. water.

CHLORO-ACETYLENE CH⋮CCl. Formed by boiling β-di-chloro-acrylic acid $CCl_2:CH.CO_2H$ with baryta-water (Wallach, *A.* 203, 87). Gas, which explodes spontaneously, forming carbon and HCl. It is stable when diluted with hydrogen, and then, when passed into bromine, forms crystalline C_2HClBr_4. With ammoniacal cuprous chloride it forms an orange pp., and in ammoniacal silver nitrate a white pp. These pps. explode violently when heated.

TRI-CHLORO-ACETYL IODIDE $CCl_3.CO.I$. (c. 180°). From tri-chloro-acetic acid and PI_3 (Gal, *C. R.* 76, 1019).

CHLORO-ACETYL-PROPIONIC ACID $C_5H_7ClO_3$. *Chloro-levulic acid.*

Ethyl ether A'Et (225°–230°), S.G. $\frac{21}{15}$ 1·196. Prepared from β-acetyl-propionic ether $CH_3.CO.CH_2.CH_2.CO_2Et$ and chlorine. Colourless pungent liquid (Conrad a. Guthzeit, *B.* 17, 2286).

CHLORO-ACETYL-UREA $NH_2.CO.NH.CO.CH_2Cl$. From urea and chloro-acetyl chloride (Tommasi, *C. R.* 76, 640). Thin needles (from alcohol). Sl. sol. boiling water. With thio-urea it forms urea, HCl, and thio-hydantoin.

Tri-chloro-acetyl-urea $NH_2.CO.NH.CO.CCl_3$. [150°]. Formed by heating tri-chloro-acetyl chloride with urea (Tommasi a. Meldola, *C. J.* 27, 404), or urea tri-chloro-acetate with P_2O_5 (De Clermont, *C. R.* 78, 848). Needles or plates; insol. cold water.

CHLORO- ACIDS *v.* CHLORO- COMPOUNDS.

α-CHLORO-ACRYLIC ACID $C_3H_3ClO_2$ *i.e.* $CH_2:CCl.CO_2H$. [65°]. (c. 178°).

Formation.—1. From αβ-di-chloro-propionic acid $CH_2Cl.CHCl.CO_2H$ by treatment with baryta or alcoholic KOH (Werigo, *A.* 170, 168; *B.* 10, 1499).—2. From α-di-chloro-propionic acid $CH_3.CCl_2.CO_2H$ and alcoholic KOH (Otto a. Beckurts, *B.* 18, 239).

Properties.—Needles; v. sol. water, but may be extracted by ether. Fuming HCl at 100° forms αβ-di-chloro-propionic acid.

Salts.—AgA′: white crystalline pp.—KA′aq: needles.—BaA'_2 2aq: plates.

β-Chloro-acrylic acid $CHCl:CH.CO_2H$. [84°].

Formation.—1. From ethyl tri-chloro-lactate (or from chloralide), zinc, and HCl in alcoholic solution (Pinner a. Bischoff, *A.* 179, 85; Wallach a. Hunaeus, *A.* 193, 23).—2. By combination of propiolic acid with HCl (Bandrowsky, *B.* 15, 2702).

Preparation.—From chloralide (50 g.), alcohol (150 g.), Zn (80 g.), HCl (80 g. of S.G. 1·24). The reaction is moderated by cooling, and after 24 hours more HCl (20 g.) and Zn (15 g.) are added. After 24 hours HCl (30 g.) is added. The alcohol and by-products are evaporated off and the remaining solution is extracted with benzene. The β-chloro-acrylic acid which is dissolved is subsequently distilled with steam. 1,000 g. of chloralide yield 12 g. of β-chloro-acrylic acid (Otto a. Fromme, *A.* 239, 264).

Properties.—Flexible laminæ, m. sol. chloroform, v. sol. water, v. e. sol. benzene. Above 15° it separates from aqueous solution in oily drops. Aqueous HCl at 80° gives $CHCl_2.CH_2.CO_2H$. Combines with bromine (1 mol.).

Salt.—AgA′.

Ethyl ether EtA′. (144°).

αβ-Di-chloro-acrylic acid $CHCl:CCl.CO_2H$. [86°].

Formation.—1. By the action of KOH on mucochloric acid (Hill, *Am.* 3, 168; *B.* 12, 656). 2. By heating per-chloro-pyrocoll octo-chloride or di-chloro-maleïmide with water at 130° (Ciamician a. Silber, *B.* 16, 2392).

Properties.—Monoclinic prisms; *a*:*b*:*c* = 1·1865:1:·3637 (Hill a. Melville, *P. Am. A.* 17, 131). Volatilises rapidly in the air. V. e. sol. water, alcohol, and ether; v. sl. sol. benzene.

Salts.—AgA′: slender needles.—KA′: felted needles.—BaA'_2aq: trimetric plates. S. 6·6 at 18°.—CaA'_2 3aq: soluble needles.

β-Di-chloro-acrylic acid $CCl_2:CH.CO_2H$(?) [77°] and [64°]. This acid may possibly be *allo*-αβ-di-chloro-acrylic acid. Formed, together with β-chloro-acrylic acid, by reducing chloralide in alcoholic solution with Zn and HCl (Wallach, *A.* 193, 20; 203, 84). Slender needles or monoclinic prisms (from chloroform) Volatile in air; but cannot be distilled. After heating to 120° it melts at 64°, but, on keeping, the melting-point rises to 77°. V. sl. sol. water; v. sol. ether and chloroform. Does not combine directly with Br. Not attacked by water at 200°. Boiling baryta-water forms chloro-acetylene.

Salts.—KA′.—AgA′.—$CaA'_2$2aq.—$ZnA'_2$2aq.

Ethyl ether EtA′. (174°). Saponified by cold KOHAq. Converted by treatment with Ag_2O at 125° and saponification of the product by $Ca(OH)_2$ into malonic acid.

Chloride $CCl_2:CH.COCl$. (Above 145°).

Amide $CCl_2:CH.CONH_2$. [113°]. Needles.

Tri-chloro-acrylic acid $CCl_2:CCl.CO_2H$. [76°]. S. 6 at 20°. From tri-chloro-bromo-propionic acid and cold baryta-water (Mabery, *Am.* 9, 3). Trimetric prisms, sl. sol. water, m. sol. hot CS_2, v. sol. alcohol, ether, and chloroform.

Salts.—KA′: irregular plates, sl. sol. cold water.—AgA′: slender needles, v. sl. sol. cold water. — CaA'_2 $3\frac{1}{2}$aq: tufts of needles. — BaA'_2 $3\frac{1}{2}$aq: branches of pearly needles.

CHLORO-ALDEHYDE *v.* Chloro-acetic aldehyde.

CHLORO-ALDOXIM $CH_3.CH:NOCl$. Formed by mixing solutions of aldoxim and hypochlorous acid; the liquid which separates being washed with water and dried over $CaCl_2$. Colourless liquid of powerful odour. Very unstable. Decomposes explosively on heating. Liberates iodine from HI (Möhlau a. Hoffmann, *B.* 20, 1507).

CHLORO-ALIZARIN *v.* Chloro-di-oxy-anthraquinone.

CHLORO-DIALLYL *v.* Hexinyl chloride.

α-CHLORO-ALLYL ACETATE $CH_2:CCl.CH_2.OAc$. (145°). Formed in small quantity, with other products, by the action of KOAc on di-chloro-propylene $CH_2:CCl.CH_2Cl$ (Henry, *B.* 5, 454).

β-Chloro-allyl acetate $CHCl:CH.CH_2OAc$. (c. 158°). From di-chloro-propylene $CHCl:CH.CH_2Cl$ and KOAc (Martinoff, *B.* 8, 1318).

α-CHLORO-ALLYL ALCOHOL C_3H_5ClO *i.e.* $CH_2:CCl.CH_2OH$. (136°) (H.); (c. 138° i. V.) (R.). S.G. ^{12} 1·164. Formed by boiling di-chloro-propylene $CH_2:CCl.CH_2Cl$ (95°) with a dilute solution of K_2CO_3 for some hours (Henry, *C. R.* 95, 849). Formed also by the action of dilute KOH or Ag_2O upon α-chloro-allyl iodide $CH_2:CCl.CH_2I$ (Van Romburgh, *R. T. C.* 1, 233).

Liquid with faint aromatic odour. Does not attack the skin. M. sol. water; gives α-chloro-allyl acetate (145°) with Ac_2O. When distilled with much water α-chloro-allyl alcohol yields acetyl-carbinol $CH_3.CO.CH_2OH$. HClO gives $CH_2Cl.CO.CH_2OH$.

β-chloro-allyl alcohol $CHCl:CH.CH_2OH$. (153° cor.) S.G. $\frac{15}{4}$ 1·162. V.D. 3·3. Formed by treating $CHCl:CH.CH_2Cl$ with aqueous KOH at 100° (Romburgh, *Bl.* [2] 36, 555). Pungent liquid, sl. sol. water. Blisters the skin. Combines with bromine.

DI-CHLORO-DI-ALLYL-AMINE $C_6H_9Cl_2N$ *i.e.* $(CH_2:CCl.CH_2)_2NH$(?) (194°). From *s*-tri-chloro-propane and alcoholic ammonia by heating for a few days at 140° (Engler, *Bl.* [2] 9, 134; *A.* 142, 72). Heavy oil, sl. sol. water.—B′HCl: deliquescent needles.—$B'_2H_2PtCl_6$.

Tetra-chloro-di-allyl-amine $C_6H_7Cl_4N$ *i.e.* $(CHCl:CCl.CH_2)_2NH$. From $CH_2Cl.CCl_2.CH_2Cl$ and alcoholic NH_3 at 120° (Fittig a. Pfeffer, *A.* 135, 363). Alkaline liquid; cannot be distilled; volatile with steam; sl. sol. water.—B′HCl: needles.—$B'H_2C_2O_4$.

CHLORO-ALLYL-BROMIDE *v.* Chloro-bromo-propane.

CHLORO-ALLYL-CHLORIDE *v.* Di-chloro-propane.

CHLORO-ALLYLENE *v.* Propargyl chloride.

CHLORO-ALLYL ETHYL OXIDE *v.* Ethyl chloro-allyl oxide.

CHLORO-ALLYL IODIDE *v.* Chloro-iodo-propane.

α-CHLORO-ALLYL NITRATE $C_3H_4ClNO_3$ *i.e.* $CH_2:CCl.CH_2.NO_3$. (140°). From α-chloro-allyl alcohol, H_2SO_4, and HNO_3 (Henry, *C. R.* 95, 849), or from α-chloro-ω-iodo-propane $CH_2:CCl.CH_2I$ and $AgNO_3$. Oil (Romburgh, *R. T. C.* 1, 238).

α-CHLORO-ALLYL THIO-CARBIMIDE C_4H_4ClNS *i.e.* $CH_2:CCl.CH_2.NCS$. (181°). From $CH_2:CCl.CH_2Cl$ and potassium sulphocyanide

(Henry, *C. R.* 95, 849; *Bl.* [2] 39, 526). Liquid, smelling like mustard. Converted by ammonia into chloro-allyl thio-urea [91°].

CHLORO-ALLYL THIO-UREA $C_4H_7ClN_2S$ *i.e.* $CH_2:CCl.CH_2.NH.CS.NH_2$. [91°]. Prepared as above (Henry, *B.* 5, 188).

CHLORO-AMIDES *v.* CHLORO-COMPOUNDS.

DI-CHLORO-AMIDO-ACETIC ETHER $C_4H_7Cl_2NO_2$ *i.e.* $CCl_2(NH_2).CO_2Et$. *Di-chloro-glycocoll. Oxamethane chloride.* From oxamic ether and PCl_5 (Wallach, *A.* 184, 8). Unstable crystals, splitting off HCl and leaving $NH:CCl.CO_2Et$ and finally $N\vdots C.CO_2Et$.

Reactions.—1. *Water* forms HCl and oxamic ether.—2. *Butyl alcohol* forms butyl oxamate; other alcohols and phenols act similarly.—3. $POCl_3$ forms $NH(POCl_2).CCl_2.CO_2Et$ [130°], which may be crystallised from chloroform or ligroïn, but is decomposed by water or heat.

***m*-CHLORO-AMIDO-BENZENE (α)-SULPHONIC ACID** $C_6H_6ClNSO_3$ *i.e.* $C_6H_3(Cl)(NH_2)(SO_3H)$ [1:3:?]. Prepared by reducing *m*-chloro-nitro-benzene (α)-sulphonic acid with ferrous hydrate. Colourless soluble needles (Post a. Meyer, *B.* 14, 1607).

***m*-Chloro-amido-benzene (β)-sulphonic acid** $C_6H_3(Cl)(NH_2)(SO_3H)$ [1:3:?]. Prepared by reduction of *m*-chloro-nitro-benzene (β)-sulphonic acid with ferrous hydrate. Plates, sl. sol. water.

Salts.—$NaA'2aq$: colourless needles. — $BaA'_2 7\frac{1}{2}aq$: colourless thick needles, v. sol. water and alcohol (Post a. Meyer, *B.* 14, 1607).

***m*-Chloro-amido-benzene (γ)-sulphonic acid** $C_6H_3(Cl)(NH_2)(SO_3H)$ [1:3:?]. Prepared by sulphonation of *m*-chlor-aniline. Sparingly soluble crystals.

Salts.—$NaA'\frac{1}{2}aq$: yellowish needles. — $NaA'2aq$: colourless needles.—BaA'_2aq: small yellow needles, sol. alcohol.—$SrA'_2 9aq$: long colourless needles, sol. alcohol and water (Post a. Meyer, *B.* 14, 1607).

Di-chloro-amido-benzene sulphonic acid $C_6H_2Cl_2(NH_2)(SO_3H)$. From amido-benzene *m*-sulphonic acid and chlorine (Beckurts, *A.* 181, 212). Slender needles (containing 2aq): sl. sol. water.

CHLORO-*o*-AMIDO-BENZOIC ACID $C_6H_3Cl(NH_2)(CO_2H)$ [1:4:5]. *Chloro-anthranilic acid.* [204°].

Formation.—From chloro-isatoïc acid and conc. HCl (Drosch, *J. pr.* [2] 33, 50).

Properties.—Long white needles (from alcohol). V. sol. glacial acetic acid, acetone, and alcohol, sol. ether, benzene, and water containing HCl, m. sol. chloroform, sl. sol. water. Its solutions have a yellowish colour and exhibit violet fluorescence.

Amide $C_6H_3Cl.(NH_2).CO.NH_2$. [172°]. By the action of hot NH_3Aq upon chloro-isatoic acid. Flat needles (from alcohol or from water). Sol. alcohol, acetone, and glacial acetic acid, less sol. chloroform, ether, benzene, and water.

Chloro-*o*-amido-benzoic acid $C_6H_3Cl(NH_2)(CO_2H)$ [1:2:3]. *Chloro-anthranilic acid.* [148°]. From chloro-nitro-benzoic acid [136°] by reduction (Cunze a. Hübner, *A.* 135, 111; Hübner a. Weiss, *B.* 6, 175). Long needles, v. sl. sol. water.—$KA'2aq$. — AgA'. — $CaA'_2 1\frac{1}{2}aq$. — $BaA'_2 1\frac{1}{2}aq$. — PbA'_2.

Chloro-*m*-amido-benzoic acid $C_6H_3Cl(NH_2)CO_2H$ [1:2:4]. [212°]. Obtaine by reducing the nitro-acid [180°] (Reveill, A. 222, 184). Formed also by boiling the diazo imide of benzoic acid with HCl (Griess, *B.* 19, 315). Reduced by sodium amalgam to *m*-amido benzoic acid. **Salts.** — PbA'_2. — CuA'_2. — $HA'H_2SO_4$.

Chloro-*m*-amido-benzoic acid $C_6H_3Cl(NH_2)CO_2H$[1:2:6]. [185°]. Formed togethe with the [1:3:4] isomeride by boiling the *m*-diazo imide of benzoic-acid $C_6H_4N_3.CO_2H$ with HC (Griess, *B.* 19, 315). White tables or smal prisms. V. sol. hot water.

Chloro-*m*-amido-benzoic acid $C_6H_3Cl(NH_2)CO_2H$ [1:4:6]. [212°]. From the nitro-acid [165°] by Sn and HCl (Wilkens a Rack, *A.* 222, 198). Brownish needles (from water); v. sol. water or alcohol. Reduced by sodium amalgam to *m*-amido-benzoic acid.

Salts.—$PbA'_2 1\frac{1}{2}aq$.—$(A'Cu)_2O$.—$HA'HCl$.—$HA'H_2SO_4$.—$HA'HNO_3$.

***s*-Chloro-*m*-amido-benzoic acid** $C_6H_3Cl(NH_2)CO_2H$ [1:3:5]. [216°]. From $C_6H_3Cl(NO_2)CO_2H$ [147°], Sn, and HCl (Hübner, *A.* 222, 90). Long needles; v. sol. alcohol or ether, sl. sol. water.

Salts.—$BaA'_2 4aq$.—AgA'.—CuA'_2.

Di-chloro-*o*-amido-benzoic acid $C_6H_2Cl_2(NH_2)CO_2H$ [1:2:4:5]. *Di-chloro-anthranilic acid.* [222°-224°]. Formed by boiling di-chloro-isatoïc acid with conc. HCl (Dorsch, *J. pr.* [2] 33, 52). Needles. V. sol. ordinary solvents, except water.

Amide $C_6H_2Cl_2(NH_2)CO.NH_2$. [284°]. From di-chloro-isatoic acid and aqueous ammonia. Short thick needles (from alcohol-acetone). Sl. sol. all solvents.

Tri-chloro-amido-benzoic acid $C_6HCl_3(NH_2)(CO_2H)$ [1:3:5:2:4]. [210°]. From tri-chloro-nitro-benzoic acid, tin, and HCl (Beilstein a. Kuhlberg, *A.* 152, 240). Small slender needles (from water); sl. sol. boiling water. Does not unite with acids.—$BaA'_2 3aq$.

Tetra-chloro-amido-benzoic acid $C_6Cl_4(NH_2).CO_2H$ [1:2:3:4:5:6]. *Tetra-chloro-anthranilic acid.* Obtained by reduction of tetra-chloro-nitro-benzoic acid with tin and HCl. Colourless amorphous solid. V. sol. alcohol, nearly insol. water (Tust, *B.* 20, 2441).

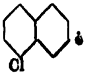
DI-CHLORO-*o*-AMIDO-BENZOIC ALDEHYDE $C_6H_3Cl_2(NH_2)CHO$. [78°]. Obtained by reduction of di-chloro-nitro-benzaldehyde with $FeSO_4$ and NH_3 (Gnehm, *B.* 17, 754). Yellow needles. Sl. sol. water.

CHLORO-AMIDO-NAPHTHALENE *v.* CHLORO-NAPHTHYLAMINE.

Chloro-di-amido-naphthalene *v.* CHLORO-NAPHTHYLENE-DIAMINE.

CHLORO-AMIDO-(α)-NAPHTHOIC LACTAM

$C_{11}H_6ClNO$ *i.e.*



[270°]. *Chloro-amido-(α)-naphthoid. Chloro-naphthostyril.* Formed by reduction of chloro-nitro-(α)-naphthoic acid [225°] with $FeSO_4$ and NH_3. Yellow needles (from alcohol) (Ekstrand, *B.* 18, 2881).

Di-chloro-amido-naphthoic lactam

$C_{10}H_4Cl_2{<}\begin{matrix}CO\\ |\\ NH\end{matrix}$ *Di-chloro-naphthostyril.* [265°].

Formed by chlorination of the lactam of amido-(α)-naphthoic acid. Also by heating nitro-(α)-naphthoic acid [215°] with excess of fuming HCl for two hours at 140°–150°. Yellow needles (from acetic acid). Sl. sol. alcohol (Ekstrand, *B.* 19, 1132).

CHLORO-*o*-AMIDO-PHENOL $C_6H_3Cl(NH_2)(OH)$ [1:3:4]. From chloro-*o*-nitro-phenol, tin, and HCl (Faust a. Saame, *A. Suppl.* 7, 193).—B′HCl: laminæ (from water).

Methyl ether $C_6H_3Cl(NH_2)(OMe)$. *Chloro-anisidine* [52°]. (260°). From the nitro-compound. White needles or prisms. Sol. alcohol, ether, and benzene. Salts.—B′HCl: colourless soluble needles.—$B_2H_2Cl_2PtCl_4$: soluble yellow needles.

Picrate $B'C_6H_2(NO_2)_3OH$: [about 200°]; yellow needles, sol. alcohol and ether, sl. sol. water.

Acetyl derivative [150°], (326°), glistening plates (Herold, *B.* 15, 1685).

Chloro-*p*-amido-phenol $C_6H_3Cl(NH_2)(OH)$ [1:3:6]. [153°]. From *p*-nitro-phenol by treatment with $KClO_3$ and HCl and reducing the product with tin and HCl (Kollrepp, *A.* 234, 6). Unstable needles, v. sol. alcohol and ether. Bleaching powder and HCl give chloro-quinone chlorimide $C_6H_3Cl(NCl)O$. Salts.—B′HCl: trimetric plates. — $B'_2H_2SO_4$ 2aq: scales.—$B'H_2C_2O_4$ 3½aq: needles. — Tartrate $B'C_4H_6O_6$: monoclinic crystals, insol. water.

Di-chloro-*o*-amido-phenol $C_6H_2Cl_2(NH_2)(OH)$ [1:3:5:6]. From di-chloro-nitro-phenol [121°] by tin and HCl (Fischer, *A. Suppl.* 7, 189). Unstable scales; reduces $AgNO_3$, forming a mirror.—B′HCl: ppd. by HCl from solution.—$B'_2H_2SO_4$.

Di-chloro-*p*-amido-phenol $C_6H_2Cl_2(NH_2)(OH)$ [1:3:5:2]. [167°]. From di-chloro-nitro-phenol [125°] by tin and HCl (Kollrepp, *A.* 234, 10; Seifart, *A. Suppl.* 7, 202). Needles (from water); may be sublimed. Oxidation gives di-chloro-quinone. HCl and bleaching powder give di-chloro-quinonimide.—B′HCl.—B′HBr: hexagonal plates; v. sl. sol. cold water.—$B'_2H_2SO_4$ 3aq: needles.—$B'HNO_3$: [110°]; plates.—$B'H_2C_2O_4$: needles.

Di-chloro-*p*-amido-phenol $C_6H_2Cl_2(NH_2)(OH)$. [173°]. Formed by passing HCl into an ethereal solution of *p*-nitroso-phenol (Jaeger, *B.* 8, 895). Needles; may be sublimed. Is perhaps identical with the preceding.

Methyl ether $C_6H_2Cl_2(NH_2)(OMe)$. [72°]. Formed by passing HCl into a solution of *p*-nitroso-phenol in MeOH (J.). Long slender needles (from dilute alcohol).

Ethyl ether. $C_6H_2Cl_2(NH_2)(OEt)$. [46°]. (275°).

Tri-chloro-*m*-amido-phenol $C_6HCl_3(NH_2)(OH)$ [1:3:5:6:2]. [95°]. Formed from tri-chloro-nitro-phenol $C_6HCl_3(NO_2)(OH)$ by reduction with tin and HCl (Daccomo, *B.* 18, 1166). Colourless silky needles. V. sol. alcohol, ether, benzene, and hot water; Fe_2Cl_6 gives a splendid violet-red colouration.

Tri-chloro-*p*-amido-phenol $C_6HCl_3(NH_2)(OH)$. [159°].

Formation.—1. From *p*-amido-phenol by chlorination; the by-products are tri- and tetra-chloro-hydro-quinone (Lampert, *J. pr.* [2] 33, 371).—2. From quinone chloro-imide and conc. HCl (Hirsch, *B.* 11, 1981; 13, 1907).

Preparation.—By passing chlorine gas into conc. HCl in which *p*-amido-phenol hydrochloride is suspended. The reaction is ended as soon as a portion of the crystalline product dissolves completely in water and gives, on adding bleaching-powder solution, flocculent tri-chloro-quinone chloro-imide, while the supernatant liquid shows no turbidity (which would be due to oily di-chloro-quinone chloro-imide). The base is precipitated by Na_2CO_3 (R. Schmitt a. M. Andresen, *J. pr.* [2] 24, 426).

Properties.—Glittering needles (from alcohol). Is a weak base, its hydrochloride being decomposed by boiling with water (Hirsch, *B.* 13, 1903).

Reactions.—1. NaOH solution and air convert it into tri-chloro-quinone.—2. By *diazo-reaction* it yields tri-chloro-phenol [54°].—3. *Bleaching-powder* and HCl give tri-chloro-quinone chlorimide. Salts.—B′HCl.—$B'_2H_2SO_4$: small needles.

CHLORO-*p*-AMIDO-PHENOL ν-SULPHONIC ACID $C_6H_3Cl(OH)(NH.SO_3H)$ [1:2:5]. Formed by adding conc. aqueous $NaHSO_3$ to mono- or di-chloro-quinone chlorimide, air being excluded (Kollrepp, *A.* 234, 21). Anhydrous needles (from hot water), which change under water to trimetric prisms (containing 2½aq). Sl. sol. cold water, insol. ether. Reduces boiling Fehling's solution. Gives a silver mirror. Converted by nitrous acid into the diazo-acid $C_6H_3ClN_2SO_4$ 3aq which crystallises in prisms. Salts.—ZnA'_2: trimetric prisms.—NiA'_2.—CuA'_2: minute yellowish-brown needles, insol. cold water.

CHLORO-*o*-AMIDO-DIPHENYL $C_{12}H_{10}ClN$ *i.e.* $C_{12}H_8Cl(NH_2)$. [48°]. Formed by reducing *o*-nitro-diphenyl with tin and HCl (Hübner a. Osten, *A.* 209, 349). Long needles (from dilute alcohol); sl. sol. water, v. e. sol. alcohol and ether. Its salts are partially decomposed by water.—B′HCl: laminæ.—$B'_2H_2PtCl_6$: orange tables.—$B'HNO_3$.—$B'_2H_2SO_4$.

Chloro-di-amido-diphenyl $C_6H_4(NH_2).C_6H_3Cl.NH_2$. Formed by allowing an alcoholic solution of benzene-azo-*p*-chloro-benzene mixed with $SnCl_2$ and a couple of drops of H_2SO_4 to stand in the cold. The base was not isolated in a pure state. The hydrochloride $B''H_2Cl_2$ forms white concentric needles (Mentha a. Heumann, *B.* 19, 2970).

Di-chloro-di-amido-diphenyl $C_6H_3Cl(NH_2).C_6H_3Cl(NH_2)$. [60°]. Formed by treating *p*-chloro-benzene-azo-*p*-chloro-benzene $C_6H_4Cl.N_2.C_6H_4Cl$ with $SnCl_2$ (Schultz, *B.* 17, 464). Glittering laminæ.—$B'H_2SO_4$.

CHLORO-DI-AMIDO-DI-PHENYL-AMINE-*o*-CARBOXYLIC ACID $C_6H_2Cl(NH_2)_2.NH.C_6H_4.CO_2H$ [c. 240°]. Formed by reduction of chloro-di-nitro-di-phenyl-amine-*o*-carboxylic acid with tin and HCl (Jourdan, *B.* 18, 1455). Colourless felted needles. Sl. sol. hot water and ether, nearly insol. benzene and ligroïn. Fe_2Cl_6 gives a brownish-violet colouration.

DI-CHLORO-TRI-AMIDO-TRI-PHENYL-CARBINOL $C_{19}H_{17}Cl_2N_3O$ *i.e.* $C(OH)(C_6H_3Cl.NH_2)_2(C_6H_4NH_2)$. *Di-chloro-para-*

rosaniline. Formed by heating *p*-toluidine (21 g.), *o*-chloro-toluidine (50 g.), and aqueous arsenic acid (106 g. of 75 p.c.) at 190° (Heumann a. Heidlberg, *B.* 19, 1989). Lustrous green mass. Dyes a much bluer shade than ordinary rosaniline.

CHLORO-AMIDO-PHENYLENE MERCAPTAN $C_6H_6ClNS_2$ *i.e.* $C_6H_3Cl(NH_2)(SH)_2$ [3:5:2:1]. From the chloride of *m*-chloro-nitro-benzene disulphinic acid by tin and HCl (Allert, *B.* 14, 1436). Does not react with formic acid.

CHLORO-AMIDO-PHENYL-ETHYLENE *v.* CHLORO-AMIDO-STYRENE.

CHLORO - AMIDO - PHENYL - GLYOXYLIC ACID *v.* ISATIN.

CHLORO-AMIDO-PHENYL MERCAPTAN $C_6H_3Cl(NH_2)(SH)$. [130°]. From *m*-chloro-nitro-benzene sulphonic acid, tin, and HCl (Allert, *B.* 14, 1435).—B'HCl.

Exo-**CHLORO**-*eso*-**AMIDO-PROPYL-PYRO-CATECHIN** *Mono-methyl ether* $C_3H_6Cl.C_6H_2(NH_2)(OMe)(OH)$ [1:5:3:4]. [97°]. From nitro-eugenol $C_3H_5.C_6H_2(NO_2)(OMe)(OH)$ by tin and HCl (Weselsky a. Benedikt, *M.* 3, 389). Pearly plates (from alcohol).—B'HCl aq.

TRI-CHLORO-AMIDO-PYRIDINE $C_5H_3Cl_3N_2$ probably

$N\begin{matrix}\diagup CCl.CH \diagdown \\ \diagdown CCl.CCl \diagup\end{matrix}C.NH_2$. [158°]. Formed in small quantity, together with di-chloro-di-oxy-amido-pyridine, tri-chloro-oxy-amido-pyridine, and tetra-chloro-amido-pyridine, by heating glutazine with PCl_5 (6 to 7 pts.). Long felted colourless needles. Sublimable. V. sol. alcohol, sl. sol. hot water. Dissolves in aqueous acids, but not in alkalis. Its *bromo-derivative* forms flat colourless needles [223°] (Stokes a. Pechmann, *B.* 19, 2710; *Am.* 8, 392).

Tetra-chloro-amido-pyridine $C_5H_2N_2Cl_4$ probably

$N\begin{matrix}\diagup CCl.CCl \diagdown \\ \diagdown CCl.CCl \diagup\end{matrix}C.NH_2$. [212°]. Formed, together with an equal quantity of tri-chloro-oxy-amido-pyridine, and small quantities of di-chloro-di-oxy-amido-pyridine and tri-chloro-amido-pyridine, by heating glutazine with PCl_5 (6 to 7 mols.). Thin colourless plates or cubical crystals. Sublimable. Sol. hot benzene, m. sol. hot alcohol, sl. sol. cold alcohol, insol. water. It does not dissolve in aqueous alkalis, and only slightly in conc. HCl. Alcoholic NaOEt forms $C_5H_2N_2Cl_3(OEt)$ [83°] and $C_5H_2N_2Cl_2(OEt)_2$ [98°] (Stokes a. Pechmann, *B.* 19, 2710; *Am.* 8, 396).

DI-CHLORO-DI-AMIDO-QUINONE $C_6Cl_2(NH_2)_2O_2$. *Chloranilamide.* Prepared by adding crystallised tetra-chloro-quinone rubbed up with alcohol to a boiling alcoholic solution of ammonia; after the tetra-chloro-quinone has dissolved, the compound separates in brown needles (Laurent, *Rev. Scient.* 19, 141; *A.* 52, 347; Knapp a. Schultz, *A.* 210, 185). Dark lustrous needles, insol. water, alcohol, and ether; readily sublimed. Its solution in alcoholic KOH is violet. Boiling $SnCl_2$ forms unstable $C_6Cl_2(NH_2)_2(OH)_2$. Fuming HNO_3 forms chloropicrin and oxalic acid.

ω-**CHLORO**-*o*-**AMIDO-STYRENE** $C_6H_4(NH_2).CH{:}CHCl$. *o-Amido-phenyl-ω-chloro-ethylene.* White concentric prisms. V. sol. alcohol and ether, v. sl. sol. cold water. Formed by reduction of *ω*-chloro-*o*-nitro-styrene with tin and HCl. By heating with sodium ethylate at about 170° it gives indole.—B'HCl: colourle needles, v. sol. water and alcohol (Lipp, *B.* 1 1071).

CHLORO-AMIDO-SULPHO-BENZOIC ACI $C_7H_6ClNSO_5$ *i.e.* $C_6H_2Cl(NH_2)(SO_3H)(CO_2H$ [1:2:*x*:3]. From chloro-*o*-amido-benzoic acid an fuming H_2SO_4 (Cunze a. Hübner, *A.* 135, 113).—BaA'': clumps.

CHLORO-AMIDO-THYMOL $C_6HClMePr(NH_2)(OH)$. [101°] (A.); [103°] (S.)

Preparation.—1. By pouring 4 vols. conc. HC upon thymo-quinone-chloro-imide (*q.v.*); the liquid begins to boil and yellow crystals separate The liquid is shaken with ether, and the ether containing chloro-thymo-quinones, is decanted; the residue, in which the chloro-amido-thymol hydrochloride is suspended, is then filtered and decomposed by Na_2CO_3. It dissolves in excess of Na_2CO_3 giving the solution a green colour. This must be avoided.—2. In a similar way from chloro-thymo-quinone-chloro-imide (*q.v.*). 3. From thymo-quinone-oxim (nitroso-thymol) and cold fuming HClAq (Sutkowski, *B.* 19, 2315).

Properties.—Glittering crystals (from water). V. sol. alcohol and ether (Andresen, *J. pr.* [2] 23, 175). Bleaching-powder forms chloro-thymoquinone chlorimide. Heating with chloranil in HOAc produces a red dye $C_{30}H_{35}Cl_3N_2O_4$ [232°].

CHLORO-AMIDO-TOLUENE *v.* CHLORO-TOLUIDINE.

CHLORO-AMIDO-XYLENE *v.* CHLORO-XYLIDINE.

exo-**Chloro-amido**-*o*-**xylene** $ClCH_2.C_6H_4.CH_2NH_2$. Formed by the action of HClAq at 200° on its phthalyl derivative (Strassmann, *B.* 21, 581).

Phthalyl derivative $[1{\cdot}2]ClCH_2C_6H_4.CH_2.N(CO)_2C_6H_4[1{\cdot}2]$. *Exo-chloro-xylene-phthalimide.* [140°]. Formed by the action of exo-di-chloro-*o*-xylene (1 mol.) on potassium phthalimide (1 mol.) at 200° (Strassmann, *B.* 21, 580). Prisms (from alcohol). Heated with HClAq to 200° it is converted into phthalic acid and exo-chloro-amido-xylene.

ω-**CHLORO-ISOAMYL ACETATE** $C_4H_9.CHCl.OAc$. (118°–128°). S.G. ^{17} ·987. From isovaleric aldehyde and AcCl (Maxwell Simpson, *Pr.* 27, 120). Liquid; slowly decomposed by water.

Tri-chloro-*sec*-**amyl-acetate** $CHMe(C_3H_4Cl_3).OAc$. (129°–134°) at 25 mm.; (227°) at 726 mm. S.G. $\frac{11{\cdot}5}{11{\cdot}5}$ 1·305. From methyl-tri-chloro-propyl carbinol and AcCl (Garzarolli-Thurnlackh, *A.* 223, 151).

CHLORO-AMYL-ALCOHOL $C_5H_{11}ClO$ *i.e.* $C_5H_{10}Cl(OH)$. *Amylene glycol chlorhydrin.* (155°). From crude amylene and aqueous HClO (Carius, *A.* 126, 199; Eltekoff, *J. R.* 14, 360). V. sol. water. Decomposed by potash with formation of amylene oxide. Na_2SO_3 forms oxy-pentane sulphonic acid (*q. v.*).

Tri-chloro-amyl alcohol $C_5H_9Cl_3O$ *i.e.* $CH_3.CHCl.CCl_2.CHMe.OH$. [50·5°]. (109°) at 20 mm.; (124°) at 41 mm. From tri-chloro-butyric aldehyde and $ZnMe_2$ in ether, followed by water (Garzarolli-Thurnlackh, *A.* 223, 149).

Properties.—Silky needles grouped in rosettes (from ether). Smells of camphor. Volatile with steam. Faintly soluble in water, v. sol. alcohol and ether. Carbonised by conc. H_2SO_4.

Reactions.—1. Warm fuming HNO_3 gives CO_2 and tri-chloro-butyric acid.—2. H_2SO_4 and $K_2Cr_2O_7$ give the ketone $C_3H_4Cl_3.CO.Me$ (191°–193°).—3. Finely divided *iron* and *acetic acid* reduce it to chloro-pentenyl alcohol (*q. v.*).

CHLORO-AMYL-ANTHRACENE $C_{19}H_{19}Cl$ or  $C_6H_4{<}\genfrac{}{}{0pt}{}{C(C_5H_{11})}{CCl}{>}C_6H_4$. [71°]. Prepared by chlorination of amyl-anthracene in $CHCl_3$ Light yellow needles with blue fluorescence.

Picric acid compound: red needles (Liebermann a. Tobias, *B.* 14, 797).

a-**CHLORO-*n*-AMYLENE** C_5H_9Cl *i.e.* $CH_3.CH_2.CH_2.CCl:CH_2$. (96°). S.G.^{51} ·872. From amylene chloride and alcoholic KOH (Bruylants, *B.* 8, 411).

ω-**Chloro-iso-amylene** $(CH_3)_2CH.CH:CHCl$. (86°). From isoamylidene dichloride $PrCH_2.CHCl_2$ and alcoholic KOH (B.).

Chloro-amylene C_5H_9Cl. *Valerylene hydrochloride.* (100°). From valerylene and fuming aqueous HCl at 100° (Reboul, *Z.* 1867, 173).

Isoprene hydrochloride C_5H_9Cl. (85°–91°). S.G. ^{0} ·885 (Bouchardat, *C. R.* 89, 1317).

Di-chloro-amylene $CH_3.CH:CCl.CHCl.CH_3$. (142°–144°) at 736 mm. From chloro-pentenyl alcohol $C_3H_4Cl.CH(OH).CH_3$ by PCl_3. Partly converted by boiling water into chloro-pentenyl alcohol (Garzarolli-Thurnlackh, *A.* 223, 160).

Di-chloro-amylene $C_5H_8Cl_2$. (146°). From tri-chloro-hexoic aldehyde and conc. KOHAq (Pinner, *A.* 179, 35; *B.* 10, 1052). Gives with bromine $C_5H_8Cl_2Br_2$ (230°–240°).

Tri-chloro-amylene $C_5H_7Cl_3$. (200°). From tetra-chloro-pentane (240°) and alcoholic KOH (Bauer, *C. R.* 51, 572).

CHLORO-AMYLENE DI-CARBAMIC ETHER $C_{11}H_{21}ClN_2O_4$ *i.e.* $C_5H_9Cl(NH.CO_2Et)_2$. [130°]. From isovaleric aldehyde, carbamic ether, and HCl (Bischoff, *B.* 7, 633).

CHLORO-DI-AMYL SULPHONE $C_5H_{10}Cl.SO_2.C_5H_{11}$. (330°). Formed together with di-chloro-di-amyl sulphone $(C_5H_{10}Cl)_2SO_2$ by treating di-amyl sulphone with ICl_3 at 130° (Spring a. Winssinger, *Bl.* [2] 41, 307).

CHLORO-ANETHOL $C_{10}H_{11}ClO$. [6°]. (258°) (Ladenburg); (229°) (Landolph). S.G. ^{0} 1·115 (Lad.); ^{22} 1·191 (Lan.). Prepared by the action of PCl_5 on anethol (Ladenburg, *A. Suppl.* 8, 90). By treatment with KOH it gives a mixture of two liquids, the first of which, $C_{18}H_{20}O_3$, boils at (268°–270°), and the second can be converted into the first by more prolonged action of the KOH (Landolph, *B.* 13, 148).

CHLORO-ANGELIC ACID $CH_3.CCl:CH.CH_2.CO_2H$ (?) [104°]. The ethyl ether is formed by treating di-chloro-angelic acid in alcoholic solution with zinc and HCl (Pinner a. Klein, *B.* 11, 1498).

Ethyl ether EtA′. Liquid.

Isomeride *v.* CHLORO-TIGLIC ACID.

Di-chloro-angelic acid $C_5H_6Cl_2O_2$ *i.e.* $CH_3.CCl:CH.CHCl.CO_2H$(?). From chloro-oxy-angelic acid and PCl_5 (Pinner a. Klein, *B.* 11, 1498). Oil.

CHLORANILIC ACID *v. p*-DI-CHLORO-*p*-DI-OXY-QUINONE.

o-**CHLORO-ANILINE** C_6H_6ClN *i.e.* $C_6H_4Cl(NH_2)$ [1:2]. Mol. w. 127½. (207° i. V.). S.G. ^{0} 1·2338.

Formation.—By reduction of *o*-chloro-nitro-benzene. May be separated from *p*-chloro-aniline by distilling the sulphates with steam, that of *o*-chloro-aniline being decomposed (Beilstein a. Kurbatoff, *A.* 176, 27).

Salts.—B′HCl: trimetric plates: S. 10 at 15°.—$B'HNO_3$: S. 10 at 13·5°.—Picrate: v. sl. sol. cold water; sl. sol. alcohol.

Acetyl derivative $C_6H_4Cl(NHAc)$. [88°]. Long flat needles (from dilute HOAc) (Beilstein a. Kurbatoff, *A.* 182, 100).

m-**Chloro-aniline** $C_6H_4Cl(NH_2)$ [1:3]. (230° i. V.). S.G. ^{0} 1·243. From *m*-chloro-nitro-benzene (B. a. K.). Its salts are hardly decomposed by boiling water.—B′HCl.—B′HBr: long red needles (Staedel, *B.* 16, 28).—$B'HNO_3$.—$B'_2H_2SO_4$: sl. sol. cold water.

Acetyl derivative $C_6H_4Cl(NHAc)$. [73°]. Needles.

p-**Chloro-aniline** $C_6H_4Cl(NH_2)$ [1:4]. [70°]. (231° i. V.).

Formation.—1. By distilling chloro-isatin with KOH (Hofmann, *A.* 53, 1).—2. By reducing *p*-chloro-nitro-benzene with $SnCl_2$.—3. From its acetyl derivative obtained by chlorinating acetanilide (Mills, *P. M.* 49, 21).

Properties.—Trimetric prisms. Is a strong base.

Salts.—B′HCl.—$B'_2H_2PtCl_6$.—$B'HNO_3$: laminæ, S. 6·7 at 12·5°.—$B'_2H_2SO_4$: sl. sol. cold water.—$B'H_2C_2O_4$ ½aq.

Acetyl derivative $C_6H_4Cl.NHAc$. [173°]. Thick needles (from dilute HOAc).

• *c*-**Di-chloro-aniline** $C_6H_3Cl_2(NH_2)$ [1:2:3]. Mol. w. 162. [24°]. (252°). From nitro-benzene by chlorination, in presence of $SbCl_3$ and reduction (Beilstein a. Kurbatoff, *A.* 196, 214; *B.* 11, 1860). Needles (from ligroïn).

Acetyl derivative $C_6H_3Cl_2(NHAc)$. [157°].

c-**Di-chloro-aniline** $C_6H_3Cl_2(NH_2)$ [3:1:2]. [39°]. From di-chloro-nitro-benzene [71°] (B. a. K.). Needles, v. sol. ligroïn.

Acetyl derivative $C_6H_3Cl_2(NHAc)$. [175°].

s-**Di-chloro-aniline** $C_6H_3Cl_2(NH_2)$ [1:3:5]. [50·5°]. (260° i. V.). From *s*-di-chloro-nitro-benzene (Witt, *B.* 8, 145; B. a. K.; Langer, *A.* 215, 120).

Acetyl derivative $C_6H_3Cl_2(NHAc)$. [187°].

Di-chloro-aniline $C_6H_3Cl_2(NH_2)$ [1:4:2]. [50°]. (251°). From di-chloro-nitro-benzene [55°] (Jungfleisch, *A. Ch.* [4] 15, 252; B. a. K.). (251°). Formed also by chlorinating *m*-chloro-aniline and by heating nitro-benzene with fuming HCl at 245° (Baumhauer, *A. Suppl.* 7, 209). CrO_3 gives di-chloro-quinone.

Acetyl derivative $C_6H_3Cl_2(NHAc)$. [132°].

Di-chloro-aniline $C_6H_3Cl_2(NH_2)$ [1:3:4]. [63°]. (245°). From acetanilide (1 mol.) and chlorine (2 mols.). Obtained also by chlorinating *o*- or *p*-chloro-aniline (Griess, *A.* 121, 268; Beilstein, *A.* 182, 95; Witt, *B.* 7, 1602).—B′HCl.—$B'_2H_2PtCl_6$.

Acetyl derivative $C_6H_3Cl_2(NHAc)$. [143°]

Di-chloro-aniline $C_6H_3Cl_2(NH_2)$ [1:2:4] [71·5°]. (272°). From di-chloro-nitro-benzene [43°], or by chlorinating *m*-chloro-aniline (B. a. K.). Long needles; strong base.

Acetyl derivative $C_6H_3Cl_2(NHAc)$. [120·5°].

c-**Tri-chloro-aniline** $C_6H_2Cl_3(NH_2)$ [1:2:3:4]. Mol. w. 196·5. [67·5°]. (292° i. V.).

Formation.—1. From its acetyl derivative. 2. By reducing $C_6H_2(NO_2)Cl_3$ [1:2:3:4].

Acetyl derivative $C_6H_2(NHAc)Cl_3$. [122°]. When chlorine is passed into a solution of acetyl *m*-chloro-aniline in strong (90 p.c.) acetic acid, two acetyl-trichloro-anilines are formed; one of these, $C_6H_2Cl_3(NHAc)$ [1:2:4:5] [185°] is hardly soluble in dilute (50 p.c.) acetic acid, the other [1:2:3:4] is soluble (Beilstein a. Kurbatoff, *A.* 192, 234).

Tri-chloro-aniline $C_6H_2Cl_3(NH_2)$ [1:3:5:6]. [77·5°]. (262° i. V.). From aniline, *p*-chloro-aniline, or (1, 3, 4)-di-chloro-aniline in glacial acetic acid by chlorine (Hofmann, *A.* 53, 35; Beilstein a. Kurbatoff, *B.* 11, 1862; Langer, *A.* 215, 114). Also from aniline and SO_2Cl_2 (Wenghöffer, *J. pr.* [2] 16, 449). Long needles (from ligroïn).

Acetyl derivative $C_6H_2Cl_3(NH_2)$. [204°].

Tri-chloro-aniline $C_6H_2Cl_3(NH_2)$ [1:2:4:5]. [96°]. From $C_6H_2(NO_2)Cl_3$ [58°] (Lesimple, *A.* 137, 125; Beilstein a. Kurbatoff, *A.* 192, 231). Obtained also by chlorinating (2, 5, 1)- or (3, 4, 1)-di-chloro-aniline, or *m*-chloro-aniline. Needles (from ligroin).

Acetyl derivative $C_6H_2Cl_3(NHAc)$. [185°].

i - **Tetra - chloro - aniline** $C_6HCl_4(NH_2)$ [1:2:3:5:6]. [88°]. Formed by chlorinating *m*-chloro-aniline (B. a. K.). Gives, by eliminating NH_2, tetra-chloro-benzene [51°].

Acetyl derivative $C_6HCl_4(NHAc)$ [174°].

s - **Tetra - chloro - aniline** $C_6HCl_4(NH_2)$ [1:2:4:5:6]. [90°]. Prepared by reducing *s*-tetra-chloro-nitro-benzene (Lesimple, *Z.* 1868, 227).

c-**Tetra-chloro-aniline** $C_6HCl_4(NH_2)$. [118°]. From *c*-tetra-chloro-nitro-benzene (Beilstein a. Kurbatoff, *B.* 11, 1862).

Acetyl derivative [154°] (Tust, *B.* 21, 1533).

Penta - chloro - aniline $C_6Cl_5NH_2$ [232°]. From *s*-di-chloro-aniline by chlorinating it in ethereal solution (Langer, *A.* 215, 120). Obtained also by reducing penta - chloro - nitro - benzene (Jungfleisch). Long white needles (from alcohol). V. sol. alcohol and ether, m. sol. benzoline. By further chlorination in acetic acid solution it gives penta - chloro - phenyl hypochlorite C_6Cl_5OCl.

CHLORO-ANISIC-ACID *v. Methyl derivative* of Chloro-oxy-benzoic acid.

CHLORO - ANISIDINE *v. Methyl ether* of Chloro-amido-phenol.

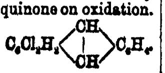
CHLORO-ANTHRACENE $C_{14}H_9Cl$. [103°]. Obtained by fusing anthracene dichloride (Perkin, *C. N.* 34, 145). Golden-yellow needles, v. sol. ether, alcohol, and benzene. The picric acid compound forms scarlet needles.

Di-(*A*)-chloro-anthracene

$C_6H_4\left<\begin{array}{c}CCl\\ |\\ CCl\end{array}\right>C_6H_4$.

[209°]. Formed by the action of (2 mols. of) chlorine upon anthracene-(*A*)-carboxylic acid or upon (*A.* 1)-chloro-anthracene-(*A.* 2)-carboxylic acid (Behla, *B.* 20, 704). Prepared by chlorinating anthracene (Laurent, *A.* 34, 294; Perkin, *C. J.* 24, 14; Græbe a. Liebermann, *A.* 160, 187; *Suppl.* 7, 284). Long yellow needles; v. sol. benzene, sl. sol. alcohol and ether. Not affected by boiling KOH. Gives anthraquinone on oxidation.

Di-chloro-anthracene

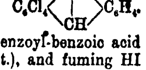


$C_6Cl_2H_2\left<\begin{array}{c}CH\\ |\\ CH\end{array}\right>C_6H_4$.

[255°]. From tetra-chloro-anthraquinone by heating with zinc-dust and aqueous ammonia (Kircher, *A.* 238, 347; *B.* 17, 1169). Slender needles. On oxidation it gives di-chloro-anthraquinone.

Tri-chloro-anthracene $C_{14}H_7Cl_3$. [163°]. From di-chloro-anthracene dichloride and alcoholic KOH (Schwarzer, *B.* 10, 378; *cf.* G. a. L.). Long golden needles (from alcohol). The alcoholic solution shows blue fluorescence.

Tetra-chloro-anthracene



$C_6Cl_4\left<\begin{array}{c}CH\\ |\\ CH\end{array}\right>C_6H_4$.

[149°]. From tetra-chloro-benzoyl-benzoic acid (1 pt.), red phosphorus (½ pt.), and fuming HI (4½ pts.) at 215° (Kircher, *A.* 238, 346). Slender needles, sol. benzene and chloroform. CrO_3 gives the corresponding tetra-chloro-anthraquinone.

Tetra-chloro-anthracene $C_{14}H_6Cl_4$. [152°]. Prepared by the action of boiling alcoholic KOH on the di-chloro-anthracene tetrachloride [206°] obtained from nitroso-anthrone and PCl_5 (Liebermann a. Lindermann, *B.* 13, 1589). Yellow needles, sol. hot acetic acid, sl. sol. alcohol. On oxidation with CrO_3 it gives crystalline dichlor-anthraquinone.

Tetra-chloro-anthracene $C_{14}H_4Cl_4$. [164°] (H.); [220°] (G. a. L.). Formed by the action of alcoholic KOH upon pure di-chloro-anthracene tetra-chloride [187°] (Hammerschlag, *B.* 19, 1108; Græbe a. Liebermann, *A. Suppl.* 7, 283). Golden yellow needles. Sl. sol. nearly all solvents. By CrO_3 and acetic acid it is oxidised to di-chloro-anthraquinone [205°].

Hexa-chloro-anthracene $C_{14}H_4Cl_6$. [320°-330°]. Yellow needles. Prepared by the action of $SbCl_5$ on di-chloro-anthracene dichloride. Oxidation with $K_2Cr_2O_7$ and H_2SO_4 gives tetra-chloro-anthraquinone (Bolas, *C. N.* 28, 167; Diehl, *B.* 11, 175).

Hepta-chloro-anthracene $C_{14}H_3Cl_7$. [above 350°]. Prepared by the prolonged action of $SbCl_5$ on di-chloro-anthracene-dichloride at 260°. Sublimes in yellow needles (Diehl, *B.* 11, 176).

Octo-chloro-anthracene $C_{14}H_2Cl_8$. [above 350°]. Feathery crystals. Prepared by the prolonged action of $SbCl_5$ at 280° on the lower chlorinated anthracenes (Diehl, *B.* 11, 177). Ruoff (*B.* 9, 1488) could only obtain hexa-chloro-benzene.

DI-CHLORO-ANTHRACENE TETRA-BROMIDE $C_{14}H_8Cl_2Br_4$. [166°] (S.); [178°] (Hammerschlag, *B.* 19, 1106). Obtained by exposing di-chloro-anthracene [209°] to bromine-vapour for a considerable time (G. a. L.; Schwarzer, *B.* 10, 376). Satiny needles (from benzene); sl. sol. alcohol and ether; v. sol. benzene and $CHCl_3$. At 180°–190° it is converted into di-chloro-bromo-anthracene [168°]. Boiling alcoholic KOH gives di-chloro-di-bromo-anthracene.

(*A.* 1)-CHLORO-ANTHRACENE-(*A.* 2)-CARBOXYLIC ACID $C_{15}H_9O_2Cl$ *i.e.*

$C_6H_4\left<\begin{array}{c}CCl\\ |\\ C(CO_2H)\end{array}\right>C_6H_4$.

[259°]. Obtained by heating anthracene with carbonyl chloride under pressure at 240°–250°; or by passing chlorine (1 mol.) into a solution of anthracene-(*A*)-carboxylic acid in $CHCl_3$. Long yellow glistening needles. Sublimes. Sol. alcohol, ether, and acetic acid; sl. sol. benzene, chloroform, and xylene; v. sl. sol. water and ligroïn. Its solutions have a blue fluorescence. At its melting-point it evolves CO_2, leaving (*A*)-chloro-anthracene. By CrO_3, $KMnO_4$, or dilute HNO_3 it is oxidised to anthraquinone. Alcoholic KOH at 160°–170° reduces it to anthracene-(*A*)-carboxylic acid. Chlorine converts it into di-(*A*)-chloro-anthracene. Salts.—KA′: very slender yellow needles.—AgA′: minute yellow prisms.—BaA'_2: thick yellowish glistening prisms (from water) or needles (from alcohol).

Methyl ether MeA′: [123°]; yellow needles or large six-sided tables; sol. alcohol, ether, &c., with a blue fluorescence; insol. water (Behla, *B.* 20, 701).

DI-CHLORO-ANTHRACENE DI-CHLORIDE $C_6H_4<\begin{smallmatrix}CCl_2\\CCl_2\end{smallmatrix}>C_6H_4$. [150°]. Formed by passing chlorine into anthracene dissolved in chloroform (Schwarzer, *B.* 10, 377). Prisms (from chloroform); sl. sol. alcohol and ether, v. sol. benzene. At 170° it yields tri-chloro-anthracene [163°]. Boiling alcoholic KOH converts it into anthraquinone.

Di-chloro-anthracene-tetra-chloride $C_{14}H_8Cl_6$. [187°] (H.); [145°] (D.). Thin white needles. Prepared by passing chlorine for a long time through a benzene solution of anthracene or di-chloranthracene [209°]. By treatment with alcoholic KOH it yields tetra-chloro-anthracene [164°] (Hammerschlag, *B.* 19, 1107; *cf.* Diehl, *B.* 11, 174).

Di-chloro-anthracene-tetrachloride $C_{14}H_8Cl_2.Cl_4$. [205°–207°]. White needles. Does not fluoresce. Prepared by heating nitroso-anthrone with PCl_5 to 180°. By boiling with alcoholic KOH it gives tetra-chloro-anthracene [152°]. (Liebermann a. Lindermann, *B.* 13, 1588).

DI-CHLORO-ANTHRACENE DISULPHONIC ACID $C_{14}H_6Cl_2(SO_3H)_2$. From (1 pt.) di-chloro-anthracene [209°] and (5 pts.) fuming H_2SO_4 at 100° (Perkin, *C. J.* 24, 15). Orange needles; v. sol. water but ppd. by HCl or H_2SO_4. Dilute solutions of the acid and its salts fluoresce blue. On oxidation it gives anthraquinone disulphonic acid.—$Na_2A''x$ aq.—BaA″.—SrA″.

CHLORO-ANTHRANILIC ACID *v.* CHLORO-AMIDO-BENZOIC ACID.

***m*-CHLORO-ANTHRAQUINONE** $C_{14}H_7ClO_2$ *i.e.* $C_6H_3Cl<\begin{smallmatrix}CO\\CO\end{smallmatrix}>C_6H_4$. [204°]. Formed by heating *m*-chloro-benzoyl-benzoic acid with sulphuric acid at 160°–175°. Yellowish-grey needles; v. sol. hot C_6H_6, sl. sol. acetic acid CS_2, and hot alcohol. Sublimes without decomposition (Græbe a. Rée, *C. J.* 49, 531).

Di-chloro-anthraquinone $C_6H_4(C_2O_2)C_6H_2Cl_2$. [205°]. Formed by oxidation of tetra-chloro-anthracene [164°] with CrO_3 and acetic acid (Hammerschlag, *B.* 19, 1109; *cf.* Graebe a. Liebermann, *A. Suppl.* 7, 290). Formed also by heating anthracene with $SbCl_5$ at 100° (Diehl, *B.* 11, 179). Glistening golden needles (from acetic acid). By NaOH fusion it gives alizarin.

Di-chloro-anthraquinone $C_6Cl_2H_2(C_2O_2)C_6H_4$. [261°]. Formed by oxidising di-chloro-anthracene [255°]. Needles (from chloroform-alcohol). Gives alizarin when fused with potash (Kircher, *B.* 17, 1169).

Tri-chloro-anthraquinone $C_{14}H_5Cl_3O_2$ [284°–290°]. Got by heating anthraquinone with $SbCl_5$ at 180° (Diehl, *B.* 11, 180). Yellow needles.

Tetra-chloro-anthraquinone $C_6Cl_4(C_2O_2)C_6H_4$ [191°]. From tetra-chloro-*o*-benzoyl-benzoic acid and H_2SO_4 at 100° (Kircher, *A.* 238, 344; *B.* 17, 1167). Golden needles (from benzene-alcohol). Oxidised by fuming HNO_3 at 140° giving tetra-chlorophthalic acid. Reduced by distillation with zinc-dust to anthracene. Yields phthalic acid on fusion with NaOH.

Di-sulphonic acid $C_{14}H_2Cl_4O_2(SO_3H)_2$. Salts.—BaA″.—CaA″.

Tetra-chloro-anthraquinone $C_{14}H_4Cl_4O_2$ [320°–330°]. Prepared by long heating of di-chloro-anthraquinone with 6 pts. of $SbCl_5$ at 200° (Diehl, *B.* 11, 180). Yellow needles

Penta-chloro-anthraquinone $C_{14}H_3Cl_5O_2$. Prepared by heating di-chloro-anthraquinone with 8 pts. $SbCl_5$ at 250° (D.). Sublimes without melting. Insoluble in the ordinary solvents

CHLORO-ATROPIC ACID $C_9H_7ClO_2$. [85°]. From tropic acid and PCl_5. Needles (Ladenburg, *B.* 12, 948).

CHLORO-AZO-BENZENE *v.* BENZENE-AZO-CHLORO-BENZENE, vol. i. p. 374.

Di-chloro-azo-benzene *v.* CHLORO-BENZENE AZO-CHLORO-BENZENE, vol. i. p. 381.

CHLORO-AZOPHENINE $C_{30}H_{23}ClN_4$. [230°]. Formed by heating *p*-chloro-*p*-nitroso-di-phenyl-amine with aniline and aniline hydrochloride at 100°. Very similar to azophenine, but more sol. benzene (O. Fischer a. Hepp, *B.* 20, 2481).

Tri-chloro-azophenine $C_{30}H_{21}Cl_3N$. [246°] (Fischer a. Hepp, *B.* 21, 676).

TRI-CHLORO-AZO-PHENOL *v.* OXY-BENZENE-AZO-PHENOL, vol. i. p. 388.

DI-CHLORO-BARBITURIC ACID $C_4H_2Cl_2N_2O_3$ *i. e.* $CCl_2<\begin{smallmatrix}CO.NH\\CO.NH\end{smallmatrix}>CO$. Formed by oxidising di-chloro-oxy-methyl-uracil with fuming HNO_3 (Behrend, *A.* 236, 64). Trimetric crystals, $a{:}b{:}c = \cdot777{:}1{:}\cdot893$. V. e. sol. alcohol and ether; sol. water.

CHLORO-BENZALDEHYDE *v.* CHLORO-BENZOIC ALDEHYDE.

CHLORO-ISOBENZALPHTHALIMIDINE *v.* CHLORO-OXY-PHENYL-ISOQUINOLINE.

CHLORO-BENZAMIDE *v.* *Amide* of CHLORO-BENZOIC ACID.

CHLORO-BENZENE C_6H_5Cl. Mol. w. 112½. [–40°]. (132°). S.G. $\frac{20}{4}$ 1·1066. μ_β 1·5369. R_∞ 50·67 (Brühl). H.F.p.—11,220. H.F.v.—12,380 (Th.). S.H. (7°–64°) ·326 (Schiff, *G.* 17, 486). *Vapour-pressure*, Ramsay a. Young (*C. J.* 47, 654). S.V. 114·3 (Schiff, *A.* 220, 98); 114·5 (Ramsay).

Formation.—1. From phenol and PCl_5 (Laurent a. Gerhardt, *A.* 75, 79; Williamson a. Scrugham, *C. J.* 7, 238; Riche, *A.* 121, 357).—2. By the action of chlorine on benzene in presence of iodine or other carriers (Hugo Müller, *C. J.* 15, 41; Fittig, *A.* 133, 49).—3. From benzene and SO_2Cl_2 at 150° (Dumas, *Z.* 1866, 705). 4. From S_2Cl_2 and benzene at 250° (Schmidt, *B.* 11, 1178).—5. By heating benzene sulphochloride with PCl_5 at 210° (Barbaglia a. Kekulé, *B.* 5, 875).—6. A solution of diazobenzene chloride, prepared from 30 grms. of aniline, and a large excess of HCl is slowly run into a nearly boiling solution of Cu_2Cl_2 in HCl (150 grms. of a 10 p.c. solution of Cu_2Cl_2). The bromo-benzene is distilled off with steam (Sandmeyer, *B.* 17, 1883).—7. By heating diazobenzene with a large excess of strong HCl; the yield is 40 p.c. of the theoretical (Gasiorowski a. Wayss, *B.* 18, 1936).

Properties.—Colourless liquid. When led through a red-hot tube it forms diphenyl, chloro-diphenyl, di-chloro-diphenyl, and di-phenyl-benzene (Kramers, *A.* 189, 135). Not affected by boiling with Al_2Cl_6. Converted by sodium into diphenyl. MnO_2 and H_2SO_4 give formic and *p*-chloro-benzoic acid (Carius, *Z.* [2] 4, 505; C. Müller, *Z.* [2] 5, 137). Chloro-benzene passes out of the system as chloro-phenyl-mercapturic acid $C_{12}H_{12}ClNSO_3$.

o-**Di-chloro-benzene** $C_6H_4Cl_2$ [1:2]. Mol. w. 147. (179° i. V.). S.G. ^{0} 1·328 (B. a. K.); 1·325 (F. a. C.).

Formation.—1. In small quantity, by chlorinating benzene (Beilstein a. Kurbatoff, *A.* 176, 42; 182, 94; *B.* 7, 1398, 1759). Separated from the greater part of the solid *p*-di-chloro-benzene by pressure; it is then heated with fuming H_2SO_4 at 210° for 2 days; this sulphonates only *o*-di-chloro-benzene. The resulting sulphonic acid is purified by crystallisation, and reconverted into di-chloro-benzene by hydrolysis (Friedel a. Crafts, *A. Ch.* [6] 10, 411).—2. From *o*-chloro-phenol and PCl_5 (B. a. K.).

Properties.—Liquid. Gives a nitro- derivative [43°]. MeCl and Al_2Cl_6 at 100° give chiefly hexa-methyl-benzene and tri-chloro-mesitylene (F. a. C.).

m-**Di-chloro-benzene** $C_6H_4Cl_2$ [1:3]. (168° uncorr.) (S.); (172°) (K.). S.G ^{0} 1·307.

Formation.—1. By running an aqueous solution of $NaNO_2$ into a hot solution of *m*-phenylene-diamine and Cu_2Cl_2 in dilute HCl (Sandmeyer, *B.* 17, 2652).—2. From di-chloro-aniline by removing NH_2 by the diazo- reaction (Körner, *G.* 4, 341; B. a. K.).—3. From *m*-di-nitro-benzene *viâ* *m*-nitro-aniline, *m*-chloro-nitro-benzene, and *m*-chloro-aniline (Griess, *P. T.* 1864 [3] 705).

Properties.—Liquid. HNO_3 (S.G. 1·4) gives a nitro-compound [32°].

p-**Di-chloro-benzene** $C_6H_4Cl_2$ [1:4]. [55°]. (173°). S.G. $^{20.5}$ 1·458; ^{53} 1·241 (Jungfleisch, *A. Ch.* [4] 14, 186). S.V.S. 117·4 (Schiff).

Formation.—1. By running a solution of $NaNO_2$ into a hot solution of *p*-phenylene-diamine and Cu_2Cl_2 in dilute HCl (Sandmeyer, *B.* 17, 2652).—2. The chief product of the action of chlorine (2 mols.) on benzene (1 mol.) in presence of iodine (Hugo Müller, *C. J.* 15, 41; *Z.* 1864, 401; Körner, *G.* 4, 324) or in presence of $MoCl_5$ (Aronheim, *B.* 8, 1400).—3. By the action of PCl_5 on phenol *p*-sulphonic acid (Kekulé, *B.* 6, 944) or on *p*-chloro-phenol (Beilstein a. Kurbatoff, *A.* 176, 32; *B.* 7, 1395, 1759).

Properties.—Monoclinic laminæ (from alcohol). Sublimes at ordinary temperatures. Fuming HNO_3 gives a nitro- derivative [55°].

u-**Tri-chloro-benzene** $C_6H_3Cl_3$ [1:3:4]. Mol. w. 181½. [16°]. (213° i. V.). S.G. (of liquid) ^{12} 1·465.

Formation.—1. By chlorination of benzene in presence of iodine (Jungfleisch, *A. Ch.* [4] 15, 264).—2. From di-chloro-aniline, $C_6H_3(NH_2)Cl_2$ [1:3:4] or [1:2:4] displacing NH_2 by Cl by means of the diazo- reaction.—3. From di-chloro-phenol [43°] and PCl_5 (Beilstein a. Kurbatoff, *A.* 192, 230; *B.* 10, 270).—4. From (β)-benzene hexa-chloride and alcoholic KOH.

Properties.—Gives on nitration a nitro- derivative [58°].

c-**Tri-chloro-benzene** $C_6H_3Cl_3$ [1:2:3]. [54°]. (219°). By eliminating NH_2 from $C_6H_2(NH_2)Cl_3$ [1:2:3:4] by diazo- reaction (Beilstein a. Kurbatoff, *A.* 192, 235). Also from (1,2,3)-di-chloro-aniline by displacing NH_2 by Cl. V. sol. CS_2 and benzene, sl. sol. alcohol. Gives a nitro- derivative [56°].

s-**Tri-chloro-benzene** $C_6H_3Cl_3$ [1:3:5]. [63·5°]. (208·5° i. V.). From ordinary tri-chloro-aniline, by eliminating NH_2 by diazo- reaction (Körner). Also from chloro-benzene tetra-chloride, and alcoholic KOH (Jungfleisch). V. sol. ether, benzene, CS_2 and light petroleum. Sol. cold alcohol and dilute (50 p.c.) acetic acid. Gives on nitration a nitro- derivative [68°] (B. a. K.), or, when fuming HNO_3 is used, a di-nitro- derivative [130°] (Jackson a. Wing, *Am.* 9, 348).

c-**Tetra-chloro-benzene** $C_6H_2Cl_4$ [1:2:3:4]. Mol. w. 216. [46°]. (254° i. V.). From tri-chloro-aniline $C_6HCl_3(NH_2)$ [1:2:3:4] or [1:3:6:2] by the diazo- reaction (Beilstein a. Kurbatoff, *A.* 192, 238). Long needles (from alcohol). Sl. sol. alcohol, v. sol. ether, light petroleum, CS_2, and strong (90 per cent.) acetic acid. Gives a nitro-derivative [65°].

i-**Tetra-chloro-benzene** $C_6H_2Cl_4$ [1:3:4:5] [51°] (B. a. K.); [35°] (I.). (246° i. V.). From ordinary tri-chloro-aniline displacing NH_2 by Cl by the diazo- reaction (Beilstein a. Kurbatoff, *A.* 192, 238). Obtained also by chlorinating benzene in sunlight (Istrati, *A. Ch.* [6] 6, 383). Colourless needles (from alcohol). Sl. sol. cold alcohol, sol. benzene, v. sol. CS_2 or light petroleum. HNO_3 (S.G. 1·54) gives a nitro- derivative [30°] (Jungfleisch, *A. Ch.* [4] 15, 204), or [22°] (B. a. K.).

s-**Tetra-chloro-benzene** $C_6H_2Cl_4$ [1:2:4:5]. [138°] (245° i. V.) (B.). S.G. ^{10} 1·734; ^{142} 1·399.

Formation.—1. By chlorination of benzene (Jungfleisch).—2. From $C_6H_2Cl_3(NO_2)$ [1:2:3:4] by reduction followed by the diazo- reaction (Beilstein a. Kurbatoff, *A.* 192, 236).—3. In small quantity by the action of chlorine on boiling tri-chloro-toluene (Beilstein a. Kuhlberg, *A.* 152, 247).—4. By the action of Fe_2Cl_6 upon (2, 4, 6, 1)-tri-chloro-phenol (Daccomo, *B.* 18, 1163).

Properties.—Crystallises best from benzene. Sl. sol. alcohol or light petroleum. Fuming HNO_3 forms, besides the nitro- compound [98°], tetra-chloro-quinone. This is the only tetra-chloro-benzene which gives chloranil under these circumstances.

Penta-chloro-benzene C_6HCl_5. [86°]. (276°) (Ladenburg, *A.* 172, 344). S.G. ^{10} 1·842. Formed by chlorinating benzene (J.), di-phenyl sulphone (Otto a. Ostrop, *A.* 141, 93; 154, 182) or tetra-chloro-benzyl chloride (Beilstein a. Kuhlberg, *A.* 152, 247). Slender needles (from alcohol); v. sl. sol. cold alcohol, v. sol. ether and CS_2. After heating for a long time with conc. or fuming H_2SO_4, on pouring the liquid into water a chestnut-brown pp. containing no sulphur and 36·8 p.c. chlorine is formed; it is called 'franceïne' by Istrati (*Bl.* [2] 48, 35); it is a red dye, and forms a red solution in alcohol.

Hexa-chloro-benzene C_6Cl_6. Mol. w. 285. [226°]. (326°). S.G. ^{232} 1·569.

Formation.—1. From methylene chloride and ICl or ICl_3 (Höland, *A.* 240, 234).—2. By passing chloroform, CCl_4, or C_2Cl_4 through a red hot tube (Juliu; Regnault, *A.* 30, 350; Basset, *C. J.* 20, 448; Berthelot a. Jungfleisch, *Z.* [2] 4, 565).—3. By chlorinating benzene in presence of $SbCl_5$ (Hugo Müller, *Z.* 1864, 40).—4. From tetrachloro-quinone (chloranil) and PCl_5 (Græbe, *A.* 146, 1).—5. Is the ultimate product of the action of $SbCl_5$ with chlorine on all chloro-toluenes and chloro-xylenes (Beilstein a. Kuhlberg, *Z.* [2] 5, 188; *A.* 150, 309).—6. By the action of chlorine in presence of ICl upon all aromatic hydrocarbons, as well as upon aniline, phenol, thymol, camphor (Ruoff, *B.* 9, 1483; 10, 1234); *sec*-hexyl iodide (Krafft, *B.* 9, 1085); and hexachloro-acetone (Cloez, *A. Ch.* [6] 9, 145).

Properties.—Thin prisms (from alcohol-benzene), v. sl. sol. boiling alcohol, sl. sol. ether, m. sol. benzene. When heated with glycerin and NaOH it gives penta-chloro-phenol.

CHLORO-BENZENE-AZO- *v.* AZO-COMPOUNDS.

CHLORO-BENZENE HEXA-CHLORIDE $C_6H_5Cl_7$. [257°]. From di-phenyl sulphone and chlorine in sunlight (Otto, *A.* 141, 101). Small dimetric prisms (from alcohol); v. sl. sol. ether, sl. sol. hot alcohol.

Di-chloro-benzene hexa-chloride $C_6H_4Cl_8$. [above 250°]. From chloro-benzene and chlorine in sunlight (Jungfleisch, *Z.* [2] 4, 486). Prisms (from chloroform); converted into penta-chloro-benzene by boiling alcoholic KOH.

Tri-chloro-benzene hexa-chloride $Cl_6C_6H_3Cl_3$ [1:2:4]. [96°]. Formed by chlorination of benzene (Willgerodt, *J. pr.* [2] 35, 415). Smells of rotten straw. V. e. sol. ether, v. sol. alcohol. Alcoholic KOH converts it into C_6Cl_6 [226°].

CHLORO-BENZENE SULPHINIC ACID $C_6H_4Cl.SO_2H$. [90°]. From chloro-benzene (*p*?)-sulpho-chloride and sodium-amalgam (Otto a. Brummer, *A.* 143, 113; 145, 323; 146, 243). Small needles or long thin columns; sl. sol. cold water. Reduced by Zn and H_2SO_4 to chloro-phenyl mercaptan, and by sodium-amalgam to benzene sulphinic acid. Oxidation gives chloro-benzene sulphonic acid.

Salts.—$NaA'_2$2aq.—CaA'_2.—BaA'_2.—PbA'_2.

Ethyl ether EtA'. [123°]. Needles.

CHLORO-BENZENE *o*-**SULPHONIC ACID** $C_6H_5ClSO_3$ *i.e.* $C_6H_4Cl(SO_3H)$ [1:2]. From amido-benzene *o*-sulphonic acid by displacement of NH_2 by Cl by means of the diazo-reaction (Bahlmann, *A.* 186, 325).

Chloride $C_6H_4Cl.SO_2Cl$ [29°].

Amide $C_6H_4Cl.SO_2NH_2$ [188°].

Chloro-benzene *m*-**sulphonic acid** $C_6H_4Cl(SO_3H)$ [1:3]. Prepared similarly from amido-benzene *m*-sulphonic acid (Kieselinsky, *A.* 180, 108). Deliquescent plates.—AgA'.—KA'.—CaA'_2.—BaA'_2 2aq.—CuA'_2 5aq.

Chloride $C_6H_4Cl(SO_2Cl)$. Oil.

Amide $C_6H_4Cl(SO_2NH_2)$: [148°]; plates.

Chloro-benzene *p*-**sulphonic acid** $C_6H_4Cl.SO_3H$ [1:4]. Formed by sulphonating chloro-benzene (Otto a. Brummer, *A.* 143, 102; Lindow a. Otto, *Z.* [2] 4, 39; Glutz, *A.* 143, 184). Also by the same method as the two preceding acids (Goslich, *A.* 180, 106). Deliquescent needles or prisms. Potash-fusion gives resorcin (Oppenheim a. Vogt, *A. Suppl.* 6, 376). The Na salt fused with KCN gives terephthalonitrile $C_6H_4(CN)_2$.

Salts.—NaA'aq.—KA'.—AgA'.—CaA'_2 1½aq.—BaA'_2 2aq.—PbA'_2 2aq.—CuA'_2 5aq.

Chloride $C_6H_4Cl.SO_2Cl$. [53°].

Bromide $C_6H_4Cl.SO_2Br$. [53°].

Amide $C_6H_4Cl.SO_2NH_2$. [144°].

Anilide $C_6H_4Cl.SO_2NPhH$. [104°]. Needles (Wallach a. Huth, *B.* 9, 426).

Di-chloro-benzene sulphonic acid $C_6H_3Cl_2(SO_3H)$ [1:2:*x*]. From *o*-di-chloro-benzene and fuming H_2SO_4 at 210° (Beilstein a. Kurbatoff, *A.* 176, 41; 182, 94).—CaA'_2 2aq.—BaA'_2 2aq.—PbA'_2 2aq.

Di-chloro-benzene sulphonic acid $C_6H_3Cl_2(SO_3H)$ [1:3:*x*]. From *m*-di-chloro-benzene and fuming H_2SO_4 at 235° (B. a. K.).—CaA'_2 2aq.—BaA'_2 aq.—PbA'_2 3aq.

Di-chloro-benzene sulphonic acid $C_6H_3Cl_2(SO_3H)$ [1:4:*x*]. From *p*-di-chloro-benzene and vapours of SO_3 (Lesimple, *Z.* [2] 4, 226). Conc. H_2SO_4 has no action even at 210° (B. a. K.). Trimetric prisms (from water).—NH_4A' aq: needles, m. sol. water.—KA'aq.—AgA'.—NaA'aq: six-sided tablets.—MgA'_2 6aq.—BaA'_2: laminæ.—PbA'_2 3aq.

Tri-chloro-benzene sulphonic acid $C_6H_2Cl_3(SO_3H)$ [1:3:4:6?]. From *u*-tri-chloro-benzene and fuming H_2SO_4 (Beilstein a. Kurbatoff, *A.* 192, 231).—CaA'_2 2aq.—BaA'_2 2aq.—PbA'_2 2aq.

CHLORO-BENZENE THIO-SULPHONIC ACID. *Chloro-phenyl ether* $C_{12}H_8Cl_2S_2O_2$ *i.e.* $C_6H_4Cl.SO_2.S.C_6H_4Cl$. [138°]. From chloro-benzene sulphinic acid and water at 130° (Otto, *A.* 145, 323). Small, four-sided, trimetric columns (from alcohol). Reduced by zinc and H_2SO_4 to chloro-phenyl mercaptan.

DI-CHLORO-BENZIDINE *v.* DI-CHLORO-DI-AMIDO-DIPHENYL.

CHLORO-BENZIL or Benzil chloride *v.* BENZILIC ACID, *Reaction* 5.

CHLORO-BENZO-TRICHLORIDE *v.* TETRA-CHLORO-TOLUENE.

o-**CHLORO-BENZOIC ACID** $C_7H_5ClO_2$ *i.e.* $C_6H_4Cl(CO_2H)$ [1:2]. Mol. w. 156½. [137°]. S. ·114 at 0°. *Electrical conductivity:* Ostwald (*J. pr.* [2] 32, 349).

Formation.—1. From salicylic acid (1 mol.) and PCl_5 (2 mols.); the mixture is distilled and the portion (above 258°) containing $C_6H_4Cl.COCl$ is decomposed by water (Chiozza, *A. Ch.* [3] 36, 102; Kolbe a. Lautemann, *A.* 115, 184; Beilstein a. Reichenbach, *A.* 132, 311; Hübner, *Z.* 1870, 293; *A.* 147, 263; Wilkins a. Rack, *A.* 222, 192). 2. By boiling *o*-chloro-toluene with dilute $KMnO_4$ (Emmerling, *B.* 8, 880).—3. By heating *m*-chloro-nitro-benzene with alcoholic KCy at 260° (Richter, *B.* 4, 463).

Properties.—Large needles. Melts under water. V. sol. hot water, alcohol, and ether. Gives a yellow pp. in neutral solutions with Fe_2Cl_6.

Reactions.—1. *Soda-fusion* gives about equal quantities of *o*- and *m*-oxy-benzoic acids (Ost, *J. pr.* [2] 11, 385).—2. In hot aqueous solution it is reduced to benzoic acid by *sodium-amalgam*. Benzoic acid so prepared was called 'salylic' acid until Beilstein a. Schlun (*A.* 133, 239) showed it to be ordinary benzoic acid contaminated with a non-volatile substance which interfered with its crystallisation.—3. Fusion with *sodium formate* gives benzoic acid (V. Meyer, *B.* 3, 363; 4, 259).

Salts.—BaA'_2 3aq.—BaA'_2. S. ·81 at 18·5°.—

CaA'_2 2aq: v. sol. water; v. sl. sol. alcohol.—AgA': scales (from boiling water).

Ethyl ether EtA'. (c. 240°) (Kekulé, *Rép. chim. pure*, 1861, 308).

Chloride $C_6H_4Cl.COCl$. (c. 237°).

Amide $C_6H_4Cl.CONH_2$: [139°]; needles; v. sl. sol. cold water; v. sol. alcohol and ether.

Anilide $C_6H_4Cl.CONPhH$: [114°]; needles.

p-Nitro-anilide $C_6H_4Cl.CO.NH.C_6H_4NO_2$: [180°]; from the anilide and HNO_3 (Wilkins a. Rack, *A.* 222, 192).

p-Toluide $C_6H_4Cl.CO.NHC_6H_4(CH_3)$: [131°]; colourless crystals; sol. alcohol, nearly insol. water (Schreib, *B.* 13, 465).

m-Nitro-p-toluide $C_6H_4Cl.CO.NHC_6H_3(CH_3)(NO_2)$: [139°]; yellowish crystals; sol. acetic acid, sl. sol. alcohol, insol. water. Prepared by nitration of the *p*-toluide.

Di-nitro-p-toluide $C_6H_4Cl.CO.NHC_6H_2(CH_3)(NO_2)_2$(?): [228°]; colourless crystals. Sl. sol. alcohol, v. sol. acetic acid and chloroform. Prepared by further nitration of the mono-nitro- compound.

Tri-nitro-p-toluide $C_{14}H_9N_4O_7Cl$: [239°]; colourless crystals. Prepared by still further nitration of the above.

m-Amido-p-toluide $C_6H_4Cl.CO.NHC_6H_3(CH_3)(NH_2)$: [153°]; colourless crystals; sol. alcohol. Prepared by reduction of the *m*-nitro-*p*-toluide.—$B'HCl$.—$B'HNO_3$.

Benzoylamido-p-toluide $C_6H_4Cl.CO.NHC_6H_3(CH_3)(NHBz)$: [178°]; colourless needles, sl. sol. alcohol.

Nitrile $C_6H_4Cl.CN$. *o-Chloro-cyano-benzene.* [43°]. (232°). From the amide and PCl_5 or P_2S_5. Also from the amide or nitrile of salicylic acid by the action of PCl_5 (Henry, *B.* 2, 492). Long needles: sl. sol. boiling water: m. sol. alcohol and ether.

***m*-Chloro-benzoic acid** $C_6H_4Cl.CO_2H$ [1:3]. [153°]. S. ·035 at 0°. *Electrical conductivity*: Ostwald, *J. pr.* [2] 32, 349.

Formation.—1. By chlorinating benzoic acid by treatment with chlorine, with HCl and $KClO_3$, or with a boiling solution of bleaching powder (Herzog, *N. Br. Arch.* 23, 15; Scharling, *A.* 41, 49; 42, 268; Stenhouse, *A.* 55, 1; Field, *A.* 65, 55; Otto, *A.* 122, 157; Hübner a. Weiss, *B.* 6, 175).—2. From *m*-amido-benzoic acid by the diazo- reaction.—3. By distilling *m*-sulpho-benzoic acid (1 mol.) with PCl_5 (2 mols.) and treating the resulting *m*-chloro-benzoyl chloride with water (Limpricht a. Uslar, *A.* 102, 259).—4. By oxidation of *m*-chloro-toluene with chromic acid mixture (Wroblewsky, *A.* 168, 200).—5. From *p*-chloro-nitro-benzene and KCy at 200° (Richter, *B.* 4, 463).—6. From *s*-chloro-amido-benzoic acid by removing NH_2 by the diazo- reaction (Hübner, *A.* 222, 91).

Properties.—Long needles or small prisms. Does not melt under water.

Reactions.—1. *Sodium amalgam* reduces it to benzoic acid (Beilstein a. Reichenbach, *A.* 132, 315).—2. *Potash-fusion* gives *m*-oxy-benzoic acid (Dembey, *A.* 148, 222).

Salts.—CaA'_2 3aq: small needles. S. 1·21 at 12°.—BaA'_2 4aq: small needles.—AgA'.

Ethyl ether $C_6H_4Cl.CO_2Et$: (245°); liquid.

Chloride $C_6H_4Cl.COCl$: (225°); liquid.

Amide $C_6H_4Cl.CONH_2$: [133°]; needles.

Nitrile $C_6H_4Cl.CN$: [39°]. Formed by distilling *m*-sulpho-benzamide with PCl_5 (Limpricht a. Uslar, *A.* 106, 35). Also from the nitrile of *m*-amido-benzoic acid by displacement of NH_2 by Cl (Griess, *B.* 2, 370). Needles; insol. water. Volatile with steam.

***p*-Chloro-benzoic acid** $C_6H_4Cl.CO_2H$ [1:4]. *Chloro-dracylic acid.* [236°]. S. ·019. *Electrical conductivity*: Ostwald, *J. pr.* [2] 32, 349.

Formation.—1. From *p*-amido-benzoic acid by diazo- reaction (Wilbrand a. Beilstein, *A.* 128, 257; Beilstein a. Schlun, *A.* 133, 242).—2. By oxidation of *p*-chloro-toluene with CrO_3 (Beilstein a. Geitner, *A.* 139, 336) or dilute $KMnO_4$ (Emmerling, *B.* 8, 880).—3. From chloro-benzene, dilute H_2SO_4, and MnO_2 (Carl Müller, *Z.* [2] 5, 137).

Properties.—Needles (by sublimation); v. sl. sol. water, v. sol. alcohol and ether. *Sodium amalgam* reduces it to benzoic acid (Hartmann, *J. pr.* [2] 12, 204).

Salts.—BaA'_2 4aq.—CaA'_2 3aq.—AgA'.

Methyl ether MeA': [42°]; needles.

Chloride $C_6H_4Cl.COCl$. [222°].

Amide $C_6H_4Cl.CONH_2$: [170°]; needles.

Anilide $C_6H_4Cl.CONPhH$: [194°]; needles.

Di-chloro-benzoic acid $C_6H_3Cl_2(CO_2H)$ [6:2:1]. Mol. w. 191. [126·5°]. Formed, together with the two isomerides [156°] and [201°], by the action of water on crude penta-chloro-toluene $C_6H_3Cl_2.CCl_3$ at 200° (Schultz, *A.* 187, 269). Slender needles; volatile with steam.

Salts.—KA' 5aq.—NH_4A' aq.—BaA'_2 3½aq. S. (of BaA'_2 in alcohol) 3·8 at 4°.—ZnA'_2 1½aq.

Chloride $C_6H_3Cl_2.COCl$: (244°); liquid.

Amide $C_6H_3Cl_2.CONH_2$: [166°]; needles.

Di-chloro-benzoic acid $C_6H_3Cl_2CO_2H$ [2:5:1]. [156°]. (301°). S. ·0850 at 14°.

Formation.—1. From chloro-nitro-benzoic acid [164°] by reduction and displacement of NH_2 by Cl by means of the diazo- reaction (Wilkens a. Rack, *A.* 222, 201).—2. From crude penta-chloro-toluene $C_6H_3Cl_2.CCl_3$, together with the acids [126·5°] and [201°] (Schultz, *A.* 187, 268).—3. By chlorinating *o*-chloro-benzoic acid in presence of $SbCl_5$ (Beilstein, *A.* 179, 286). Occurs also among products of chlorination of benzoic acid.—4. By oxidising (6, 3, 1)-di-chloro-ethyl-benzene with chromic mixture (Istrati, *A. Ch.* [6] 6, 479).—5. From $C_6H_3MeCl_2$ [1:2:5] and dilute HNO_3 (Lellmann a. Klotz, *A.* 231, 319).

Needles (from water); slightly volatile with steam. Heated with dilute H_2SO_4 at 220° it gives CO_2 and *p*-dichloro-benzene.—BaA'_2 3aq. S. (of BaA'_2) 2·5 at 14·4°.—CaA'_2 2aq.—PbA'_2 aq.—CuA'_2 2aq (B.).—CuA'_2 aq (I.).—FeA'_2.—KA' 2aq. NH_4A': slender needles.—AgA'.

Ethyl ether EtA'. (271° i. V.). S.G. ^{0} 1·328.

Amide $C_6H_3Cl_2.CONH_2$: [155°]; needles (B.).

Anilide: [240°]; prisms (from benzene).

Di-chloro-benzoic acid $C_6H_3Cl_2(CO_2H)$ [3:2:1]. [156°] (C.); [166°] (S.). Formed, together with the isomeride [201°], by chlorination of benzoic acid (Claus, *B.* 5, 658; 6, 721; 8, 948; 20, 1621). Formed also by oxidising *c*-di-chloro-toluene with $KMnO_4$ (Seelig, *A.* 237, 162). Not affected by dilute H_2SO_4 at 220°. Distillation over lime gives *o*-di-chloro-benzene. Not decomposed by conc. H_2SO_4 at 300°.—BaA'_2 3aq. S. 8 at 28°.

Di-chloro-benzoic acid $C_6H_3Cl_2(CO_2H)$ [4:2:1]. [158°]. From $C_6H_3MeCl_2$ [1:2:4] and dilute HNO_3 (Lellmann a. Klotz, *A.* 231, 315).

Salt.—BaA'_2 3½aq.

Di-chloro-benzoic acid $C_6H_3Cl_2(CO_2H)$ [3:5:1]. [182°]. From $C_6H_3MeCl_2$ and dilute HNO_3 (Lellmann a. Klotz, *A.* 231, 324). Needles (from dilute alcohol). May be sublimed.

Di-chloro-benzoic acid $C_6H_3(CO_2H)Cl_2$ [4:3:1]. [201°].

Formation.—1. A product of the chlorination of benzoic acid (Beilstein a. Kuhlberg, *A.* 152, 232; 179, 291).—2. From chloro-sulpho-benzoic acid and PCl_5 (Otto, *A.* 123, 226).—3. By oxidation of $C_6H_3Cl_2.CH_3$ or $C_6H_3Cl_2.CH_2Cl$; or by heating $C_6H_3Cl_2.CCl_3$ with water at 200° (B. a. K.). 4. From *p*-chloro-benzoic acid and $SbCl_5$ at 200° (B.).—5. From chlorinated *p*-oxy-benzoic acid and PCl_5 (Lössner, *J. pr.* [2] 13, 433).—6. From $C_6H_3MeCl_2$ [1:3:4] by dilute HNO_3 (Lellmann a. Klotz, *A.* 231, 313).

Properties.—Very slender needles (from water); volatile with steam.

Salts.—CaA'_2 3aq.—BaA'_2 4aq. S. 1·1 at 18°.

Ethyl ether EtA': (263°); liquid.

Chloride $C_6H_3Cl_2.COCl$: (242°); liquid.

Amide $C_6H_3Cl_2.CONH_2$: [133°]; needles.

Tri-chloro-benzoic acid $C_6H_2Cl_3(CO_2H)$ [6:3:2:1]. [c. 80°]. From the corresponding aldehyde and $KMnO_4$ (Seelig, *A.* 237, 150). Needles, v. sol. water.

Tri-chloro-benzoic acid $C_6H_2Cl_3(CO_2H)$ [4:3:2:1]. Mol. w. 225½. [129°]. From the corresponding (4, 3, 2, 1)-tri-chloro-benzoic aldehyde by $KMnO_4$ (Seelig, *A.* 237, 150). Needles; m. sol. water.

Tri-chloro-benzoic acid $C_6H_2Cl_3(CO_2H)$ [5:4:2:1]. [163°]. From *s*-tri-chloro-toluene by oxidation with chromic acid mixture (Jannasch, *A.* 142, 301). Formed also by boiling benzoic acid with water and bleaching-powder for a long time; and by heating $C_6H_2Cl_3.CCl_3$ with water at 260° (Beilstein a. Kuhlberg, *A.* 152, 234). Slender needles (from water or by sublimation); v. sl. sol. cold water.

Salts.—NH_4A'.—CaA'_2 2aq.—BaA'_2 7aq.—SrA'_2 4aq.

Ethyl ether EtA': [65°]; needles.

Chloride $C_6H_2Cl_3.COCl$. [41°]. (272°).

Amide $C_6H_2Cl_3.CONH_2$: [168°]; needles.

Tri-chloro-benzoic acid $C_6H_2Cl_3(CO_2H)$ [5:4:3:1]. [203°].

Formation.—1. From di-nitro-*p*-amido-benzoic acid and fuming HCl at 210° (Salkowski, *A.* 163, 28).—2. From crude hexa-chloro-toluene $C_6H_2Cl_3.CCl_3$ and NaOH (Claus a. Bücher, *B.* 20, 1626).

Properties.—Slender needles (from dilute alcohol or by sublimation).

Salts.—AgA'.—BaA'_2 4aq.—CaA'_2 6aq.

Ethyl ether EtA': [86°]; slender needles (S.).

Chloride $C_6H_2Cl_3.COCl$. [36°] (S.).

Amide $C_6H_2Cl_3.CONH_2$. [176°] (S.).

c-Tetra-chloro-benzoic acid $C_6HCl_4(CO_2H)$. [165°]. Formed by chlorination of the di-chloro-benzoic acids melting at [201°] and [156°] (Claus) by heating with MnO_2 and fuming HCl at 190° (Claus a. Bücher, *B.* 20, 1626). Also from di-chloro-benzoic acid [156°] and $SbCl_5$ at 230° (Beilstein, *A.* 179, 286).—BaA'_2 4aq (B.).—BaA'_2 3½aq (C.).

Tetra-chloro-benzoic acid $C_6HCl_4(CO_2H)$ [5:4:3:2:1]. [186°]. Prepared by heating tetra-chloro-phthalic acid with acetic acid (2 or 3 pts.) at 300° for 3 or 4 hours (Tust, *B.* 20, 2439; 21, 1532.) Long colourless needles. V. sol. alcohol and ether, v. sl. sol. water.

Salts.—A'_2Ca 4aq: long colourless needles; m. sol. hot water.—A'_2Cu 3½aq.—BaA'_2 3½aq.

Ethyl ether A'Et: [35°]; long colourless needles.

Tetra-chloro-benzoic acid $C_6HCl_4(CO_2H)$ [6:4:3:2:1]? [186°]. From hepta-chloro-toluene $CHCl_4.CCl_3$ and water at 280° (Beilstein a. Kuhlberg, *A.* 152, 245).

Penta-chloro-benzoic acid $C_6Cl_5(CO_2H)$. [200°]. Formed by chlorination of the di-chloro-benzoic acids [201°] and [156°] with MnO_2 and HClAq at 190° (C. a. B.).—BaA'_2 4aq: stellate groups of needles.

Nitrile $C_6Cl_5(CN)$. [210°]. Formed by exhaustive chlorination of benzonitrile with $SbCl_5$ (Merz a. Weith, *B.* 16, 2885). Colourless needles. Sublimable. V. sol. hot alcohol, chloroform, and CS_2, sl. sol. cold alcohol and ether. It is very stable towards HCl at high temperatures. Alcoholic NaOH removes all its chlorine at 200°.

o-**CHLORO-BENZOIC ALDEHYDE** [2:1] $C_6H_4Cl.CHO$. (c. 215°). S.G. $\frac{8}{}$ 1·29. Formed by heating tri-chloro-toluene $C_6H_4Cl.CHCl_2$ (from salicylic aldehyde and PCl_5) with water at 170° or with ($\frac{9}{16}$ pt.) dry oxalic acid at 130° (Henry, *B.* 2, 135; Anschütz, *A.* 226, 19). Oil, smelling of almonds; volatile with steam. Forms a crystalline compound with $NaHSO_3$.

p-**Chloro-benzoic aldehyde** [4:1] $C_6H_4Cl.CHO$. [48°]. (c. 212°). Obtained by boiling $C_6H_4Cl.CHBr_2$ [48°] (10 pts.) with lead nitrate (4 pts.) and water (100 pts.) for three days, in presence of CO_2 (Jackson a. White, *Am.* 3, 31; *N. Am. A.* 15, 268; *B.* 11, 1042). Formed by boiling $C_6H_4Cl.CH_2Cl$ with aqueous lead nitrate. Formed also by passing chlorine into benzoic aldehyde containing iodine (Beilstein a. Kuhlberg, *A.* 147, 339). Long needles; may be sublimed. Sol. alcohol, ether, CS_2, and HOAc, sl. sol. water. Absorbs oxygen from the air. Forms a crystalline compound with $NaHSO_3$.

Di-chloro-benzoic aldehyde $C_6H_3Cl_2.CHO$ [5:2:1]. [58°]. (230°–233°). Preparation not given. White crystals. On oxidation it gives di-chloro-benzoic acid [152°] (Gnehm, *B.* 17, 752).

Di-chloro-benzoic aldehyde $C_6H_3Cl_2.CHO$ [6:2:1]. [68°]. Formed by heating $C_6H_3Cl_2.CHCl_2$ with water at 200° (Beilstein a. Kuhlberg, *A.* 152, 224). Slender needles; volatile with steam; sl. sol. hot water. Attacks the eyes. Combines with $NaHSO_3$. Oxidises to di-chloro-benzoic acid [128°].

(*β*)-**Di-chloro-benzoic aldehyde** $C_6H_3Cl_2.CHO$ [4:2:1]. [71°]. (c. 233°). Formed by the action of conc. H_2SO_4 on $C_6H_3Cl_2.CHCl_2$. The aldehyde is separated by means of the double compound with sodium bisulphite (Seelig, *A.* 237, 167). White needles (from alcohol). Oxidation with permanganate yields (*β*)-dichloro-benzoic acid [158°]. When heated with Ac_2O and NaOAc it forms (*β*)-di-chloro-cinnamic acid [228°].

Tri-chloro-benzoic aldehyde $C_6H_2Cl_3.CHO$ [113°]. Formed by heating $C_6H_2Cl_3.CHCl_2$ (281°) with water at 250° (B. a. K.; Seelig, *B.* 18, 420; *A.* 237, 148). Very slender needles;

insol. boiling water, v. sol. alcohol; volatile with steam. Conc. H_2SO_4 and KNO_3 form tri-chloro-nitro-benzoic acid [222°] and an aldehyde [124°].

Tri-chloro-benzoic aldehyde $C_6H_2Cl_3.CHO$ [4:3:2:1]. [90°]. From penta-chloro-toluene $C_6H_2Cl_3.CHCl_2$ [84°] (Seelig). Gives on oxidation tri-chloro-benzoic acid [129°].

CHLORO-BENZONITRILE v. Nitrile of Chloro-benzoic acid.

CHLORO-BENZOPHENONE $C_6H_4Cl.CO.C_6H_5$. *Phenyl chloro-phenyl ketone.* [76°]. (above 300°). From chloro-benzene, benzoic acid, and P_2O_5 Kollarits a. Merz, *B.* 6, 547). Flat needles (from ether-alcohol); v. sol. ether, sl. sol. cold alcohol and ligroïn.

CHLORO-*o*-BENZOYL-BENZOIC ACID $C_{14}H_9ClO_3$ *i.e.* $C_6H_5.CO.C_6H_3Cl(CO_2H)$ [2:4or5:1]. *Chloro-benzophenone carboxylic acid.* [171°]. From chloro-phthalic anhydride [97°], benzene, and Al_2Cl_6 (Græbe a. Rée, *C. J.* 49, 531; *A.* 238, 239). Minute monoclinic prisms; v. sol. ether and alcohol, sl. sol. CS_2, v. sl. sol. light petroleum. Conc. H_2SO_4 converts it into chloro-anthraquinone [204°].

Di-chloro-*o*-benzoyl-benzoic acid $C_6H_5.CO.C_6H_2Cl_2.CO_2H$. [159°]. From (β)-di-chloro-phthalic anhydride [150°], benzene, and Al_2Cl_6 (Le Royer, *A.* 238, 356). Needles (from dilute alcohol).

Tetra-chloro-*o*-benzoyl-benzoic acid $C_{14}H_6Cl_4O_3$ *i.e.* $C_6H_5.CO.C_6Cl_4.CO_2H$. [200°]. From tetra-chloro-phthalic anhydride, benzene, and Al_2Cl_6 (Kircher, *A.* 238, 338). White needles; sl. sol. cold benzene, v. e. sol. alcohol, insol. water. Cannot be distilled or sublimed.

Reactions.—1. *Soda-fusion* gives benzoic acid. 2. H_2SO_4 and PCl_5 give tetra-chloro-anthraquinone.—3. HI gives tetra-chloro-benzyl-benzoic acid.

Salts.—NaA′4aq. S. 1·7 at 20°.—KA′ 1½aq. —CuA′₂ 2aq.—CuA′₂CuO.

Ethers: EtA′ [90°].—MeA′ [92°].

Chloride [183°]. Needles.

CHLORO-BENZOYL CHLORIDE v. *Chloride* of Chloro-benzoic acid.

CHLORO-DIBENZYL v. Chloro-di-phenyl-ethane.

***p*-CHLORO-BENZYL ACETATE** $C_9H_9ClO_2$ *i.e.* [4:1] $C_6H_4Cl.CH_2.OAc$. (240°). From $C_6H_4Cl.CH_2Cl$ and KOAc in boiling alcohol (Beilstein a. Kuhlberg, *A.* 147, 344).

Di-chloro-benzyl acetate $C_6H_3Cl_2.CH_2OAc$. (259°). Similarly prepared from $C_6H_3Cl_2.CH_2Cl$ (B. a. K.).

CHLORO-BENZYL-ACETO-ACETIC ETHER $C_{13}H_{15}ClO_3$ *i.e.* $CH_3.CO.CH(CHClPh).CO_2Et$(?) [41°]. Formed, together with an isomeride [72°] possibly $CH_3.CO.CCl(CH_2Ph).CO_2Et$, by mixing aceto-acetic ether with benzoic aldehyde and saturating with HCl (*v.* vol. i. p. 24).

***p*-CHLORO-BENZYL ALCOHOL** C_7H_7ClO *i.e.* $C_6H_4Cl.CH_2OH$. [66°] (B. a. K.); [71°] (J. a. F.). Obtained by heating *p*-chloro-benzyl acetate (*v. supra*) with alcoholic NH_3 at 160° (Beilstein a. Kuhlberg, *A.* 147, 344; Neuhof, *Z.* [2] 3, 467). Prepared by boiling *p*-chloro-benzyl chloride $C_6H_4Cl.CH_2Cl$ with water (Jackson a. Field, *Am.* 2, 88; *P. Am. A.* 14, 56). Needles (by sublimation or from water): may be distilled. Sol. hot water, alcohol, and ether. Chromic mixture oxidises it to *p*-chloro-benzoic acid [238°].

Di-chloro-benzyl alcohol $C_6H_3Cl_2.CH_2OH$. [77°]. From the acetate (*v. supra*) by heating with alcoholic ammonia at 180° (B. a. K.). Needles; v. sl. sol. water.

Tri-chloro-benzyl alcohol $C_6H_2Cl_3.CH_2OH$. From tri-chloro-benzyl chloride $C_6H_2Cl_3.CH_2Cl$ and alcoholic KOAc at 150°. Crystalline (Beilstein a. Kuhlberg, *A.* 152, 241).

Tetra-chloro-benzyl alcohol $C_6HCl_4.CH_2OH$. From $C_6HCl_4.CH_2Cl$, alcohol, and KOAc at 180°; crystallised from water (B. a. K.).

Penta-chloro-benzyl alcohol $C_6Cl_5.CH_2OH$. [193°]. From $C_6Cl_5.CH_2Cl$, alcohol, and KOAc at 200° (B. a. K.). White needles (from benzene-alcohol); insol. water, sl. sol. boiling alcohol.

***p*-CHLORO-BENZYLAMINE** C_7H_8ClN *i.e.* [4:1] $C_6H_4Cl.CH_2NH_2$. *p*-Chloro-benzyl chloride (1 vol.) heated with alcoholic ammonia (2 vols.) at 100° forms $(C_6H_4Cl.CH_2)NH_2$, $(C_6H_4Cl.CH_2)_2NH$ and $(C_6H_4Cl.CH_2)_3N$. Their hydrochlorides may be separated by crystallisation from alcohol (Berlin, *A.* 151, 137; Jackson a. Field, *Am.* 2, 94; *P. Am. A.* 14, 56). Colourless oil; sol. ether.

Salts.—*B′HCl: [241°]; narrow plates, sol. water and alcohol.—$B'_2H_2PtCl_6$: yellow needles. *B′HBr: [230°]; decomposed by melting.—*$B'_2H_2CO_3$: [115°]; plates (from water) or needles (from alcohol).

Di-*p*-chloro-di-benzyl-amine $(C_6H_4Cl.CH_2)_2NH$. [29°]. From chloro-benzyl bromide and alcoholic NH_3 (Jackson a. Field, *Am.* 2, 90; *B.* 11, 904). White blades; insol. water, sol. alcohol, ether, benzene, and CS_2.

Salts.—B′HCl: [288°]; plates, sol. water and alcohol, insol. ether.—$B'_2H_2PtCl_6$: yellow scales, sl. sol. boiling water, insol. alcohol.—B′HBr: [280°–290°], melting with decomposition. Scales, sl. sol. water, insol. ether.

(β)-Di-chloro-di-benzyl-amine $(C_6H_4Cl.CH_2)_2NH$. This base occurs, together with the two following, among the products of the action of alcoholic NH_3 on crude chloro-benzyl chloride (Berlin, *A.* 151, 141).—B′HCl: [228°]. B′HBr: [224°].—B′HI: [215°].—$B'HNO_3$: [204°].

(γ)-Di-chloro-di-benzyl-amine $(C_6H_4Cl.CH_2)_2NH$. Salts.—B′HCl: [220°].—B′HBr: [212°].—B′HI: [187°].—$B'HNO_3$: [193°].

(δ)-Di-chloro-di-benzyl-amine $(C_6H_4Cl.CH_2)_2NH$. Salts.—B′HCl: [222°].—B′HBr: [199°].—B′HI: [218°].—$B'HNO_3$: [179°].

Tri-*p*-chloro-tri-benzyl-amine $(C_6H_4Cl.CH_2)_3N$. [79°]. From *p*-chloro-benzyl bromide and alcoholic NH_3 (J. a. F.). Needles; sol. hot alcohol, ether, benzene, and CS_2.

Salts.—B′HCl 2aq: [196°].—B′ H_2PtCl_6: pale orange plates, insol. water, alcohol, and ether.

TETRA-CHLORO-*o*-BENZYL-BENZOIC ACID $C_6H_5.CH_2.C_6Cl_4.CO_2H$. *Tetra-chloro-di-phenyl-methane oso-carboxylic acid.* [157°]. From $C_6H_5.CO.C_6Cl_4.CO_2H$ and conc. HI at 180° (Kircher, *A.* 238, 348). Hair-like needles (from dilute alcohol). Insol. water, v. sol. alcohol.

Salts.—NaA′4aq.—AgA′.

CHLORO-BENZYL BROMIDE v. Chloro-bromo-toluene.

CHLORO-BENZYL CHLORIDE v. Di-chloro-toluene.

CHLORO-BENZYL CYANIDE v. *Nitrile* of Chloro-phenyl-acetic acid.

_p_-CHLORO-BENZYL ETHYL OXIDE $C_6H_4Cl.CH_2.O.C_2H_5$. (217°) (Sintenis, *A.* 161, 335); (215°–225°) (Jackson a. White, *Am.* 2, 170); (226°) (Errera, *G.* 17, 206). From *p*-chloro-benzyl chloride (acetate or bromide) and alcoholic KOH (Naquet, *A. Suppl.* 2, 251). Liquid, with fruity odour; decomposed by heating above its boiling-point into *p*-chloro-benzoic aldehyde and ethane (E.).

ω-CHLORO-BENZYLIDENE-ANILINE $C_6H_5.N:CCl.C_6H_5$ *Benzanilide-imide-chloride.* [41°]. Formed by isomeric change of the first formed oxim-chloride $(C_6H_5)_2C:NCl$ by the action of PCl_5 or $POCl_3$ upon benzophenone-oxim $(C_6H_5)_2C:NOH$. Colourless rhombic tables (Beckmann, *B.* 19, 989).

CHLORO-BENZYLIDENE CHLORIDE *v.* TRI-CHLORO-TOLUENE.

_o_-CHLORO-BENZYLIDENE-MALONIC ACID $C_{10}H_7ClO_4$ *i.e.* $C_6H_4Cl.CH:CH(CO_2H)_2$. [192°]. Formed by heating malonic acid with *o*-chloro-benzoic aldehyde and HOAc for some hours at 100° (Stuart, *C. J.* 53, 141). Decomposes on melting into CO_2 and chloro-cinnamic acid. Boiling water splits it up into *o*-chloro-benzoic aldehyde and malonic acid.

ω-CHLORO-BENZYLIDENE-(α)-NAPHTHYLAMINE $C_6H_5CCl:N.C_{10}H_7$. [60°]. From benzoyl-(α)-naphthylamine and PCl_5 (Just, *B.* 19, 979).

ω-Chloro-benzylidene-(β)-naphthylamine. [68°]. Similarly prepared (J.). Leaflets; slowly converted into benzoyl-(β)-naphthylamine on exposure to the air.

CHLORO-BENZYLIDENE-PHTHALIMIDINE $C_{15}H_{10}ClNO$. [232°]. From benzylidene-phthalimidine and PCl_5 (Gabriel, *B.* 18, 1260). Needles (from alcohol).

ω-CHLORO-BENZYLIDENE-_o_-TOLUIDINE $C_{14}H_{12}ClN$ *i.e.* $C_6H_4Me.N:CCl.C_6H_5$ *Benzoyl-o-toluidine-imide-chloride.* Formed by the action of PCl_5 upon benzoyl-*o*-toluidine. Water regenerates benzoyl-*p*-toluidine. The compound was not obtained in a pure state. With sodio-malonic ether it gives *o*-tolyl-β-imido-benzyl-malonic ether $C_6H_5.C(NC_7H_7).CH(CO_2Et)_2$ (Just, *B.* 19, 982).

ω-Chloro-benzylidene-_m_-toluidine $C_{14}H_{12}ClN$ *i.e.* $C_6H_4Me.N:CCl.C_6H_5$. Formed by the action of PCl_5 upon benzoyl-*m*-toluidine. Not obtained in a pure state. By the action of sodio-malonic ether it yields *m*-tolyl-β-imido-benzyl-malonic ether $C_6H_5.C(NC_7H_7).CH(CO_2Et)_2$ (Just, *B.* 19, 983).

ω-Chloro-benzylidene-_p_-toluidine $C_6H_4Me.N:CCl.C_6H_5$. [52°]. Formed by gently warming benzoyl-*p*-toluidine with PCl_5. Large clear prismatic crystals. By boiling with water or alcohol it is reconverted into the benzoyl-*p*-toluidine. With *p*-toluidine it yields di-*p*-tolyl-benzamidine $C_6H_5.C(NC_7H_7)NHC_7H_7$. With sodio-malonic ether it gives *p*-tolyl-β-imido-benzyl-malonic ether $C_6H_5.C(NC_6H_4Me).CH(CO_2Et)_2$ (Just, *B.* 19, 979).

CHLORO-BENZYL-MALONIC ETHER $C_6H_5.CH_2.CCl(CO_2Et)_2$. (305°). S.G. $\frac{12}{15}$ 1·150. Prepared by the action of benzyl chloride (26 pts.) on chloro-malonic ether (38·8 pts) and NaOEt (from 4·6 pts. Na and 70 pts. alcohol) (Conrad, *A.* 209, 243; *B.* 13, 2159). Liquid. Decomposed by KOH into alcohol, benzyl-tartronic acid $C_6H_5.CH_2.C(OH)(CO_2H)_2$, and a little cinnamic acid.

Amide $C_8H_7Cl(CO.NH_2)_2$. (c. 80°). White needles. Sol. alcohol, insol. water. (Bischoff a. Emmert, *B.* 15, 1112).

_p_-CHLORO-BENZYL MERCAPTAN C_7H_7ClS *i.e.* [4:1] $C_6H_4Cl.CH_2.SH$. [20°] (J. a. W.). From *p*-chloro-benzyl bromide (or chloride) and alcoholic KHS (Beilstein, *A.* 116, 347; 147, 346; Jackson a. White, *Am.* 2, 167; *P. Am. A.* 14, 312). Nauseous liquid or white crystals. Mixes with alcohol, ether, benzene, and CS_2.—$(C_7H_6ClS)_2Hg$: from the mercaptan and ppd. HgO; needles; insol. water, sl. sol. ether and alcohol.

DI-_p_-CHLORO-DI-BENZYL SULPHIDE $C_{14}H_{12}Cl_2S$ *i.e.* $(C_6H_4Cl.CH_2)_2S$. [42°]. From *p*-chloro-benzyl bromide and alcoholic Na_2S (Jackson a. White, *P. Am. A.* 14, 312; *Am.* 2, 166; *B.* 13, 1217). Thick needles, insol. water, v. sol. alcohol, ether, benzene and CS_2.

Di-_p_-chloro-di-benzyl disulphide $C_{14}H_{12}Cl_2S_2$ *i.e.* $(C_6H_4Cl.CH_2)_2S_2$. [59°]. From *p*-chloro-benzyl bromide and alcoholic Na_2S_2 (J. a. W.). Flat needles, with disagreeable smell. V. sol. alcohol, HOAc, ligroïn, ether, benzene, and CS_2.

_p_-CHLORO-BENZYL SULPHOCYANIDE $C_6H_4Cl.CH_2S.CN$. [17°]. Prepared by boiling an alcoholic solution of *p*-chloro-benzyl bromide with KCNS (Jackson a. Field, *Am.* 2, 91). White flat needles.

DI-_p_-CHLORO-DI-BENZYL-SULPHONE $C_{14}H_{12}Cl_2SO_2$ *i.e.* $(C_6H_4Cl.CH_2)_2SO_2$. [165°]. Formed, together with $C_6H_4Cl.CH_2SO_3H$, by the action of K_2SO_3 on *p*-chloro-benzyl chloride (Henninger a. Vogt, *A.* 166, 374). Prepared by oxidising *p*-chloro-benzyl sulphide with CrO_3 (Jackson a. White, *Am.* 2, 167; *P. Am. A.* 14, 312). Very small needles (from alcohol); insol. water, sol. alcohol, ether, HOAc, and CS_2.

Isomerides [149°] and [185°] are formed when crude chloro-benzyl chloride is used (H. a. V.).

CHLORO-BENZYL SULPHONIC ACID *v.* CHLORO-TOLUENE SULPHONIC ACID.

DI-_p_-CHLORO-DI-BENZYL DI-SULPHOXIDE $(C_6H_4Cl.CH_2)_2S_2O_2$. [120°]. Obtained by oxidising di-*p*-chloro-di-benzyl disulphide with CrO_3 in HOAc (Jackson a. White, *Am.* 2, 169; *P. Am. A.* 14, 315). Waxy solid, becoming crystalline; insol. water, v. sol. alcohol and ether.

DI-CHLORO-BETORCIN $C_6Cl_2Me_2(OH)_2$. [142°]. Prepared by adding tetra-chloro-betorcin in small portions to boiling hydric iodide (1[illegible] p.c.). Crystallised from light petroleum (50 pts.) (Stenhouse a. Groves, *C. J.* 37, 395). Colourless needles. Sol. CS_2, benzene and ether.

Tetra-chloro-betorcin $C_6Cl_2Me_2(OCl)_2$. [109°]. Prepared by adding a solution of betorcin to a slight excess of chlorine hydrate (ice and water saturated with Cl). The crystals which separate after 12 hours are recrystallised from light petroleum. The yield is quantitative (Stenhouse a. Groves, *C. J.* 37, 399).

Properties.—Large white prisms. V. sol. benzene and ether, insol. water.

CHLORO-BROMAL *v.* CHLORO-DI-BROMO-ACETIC ALDEHYDE.

CHLORO-BROMALIDE $C_5H_2Cl_4Br_2O_3$. [122°]. Colourless prisms. Formed by heating di-chloro-bromo-acetic aldehyde with H_2SO_4 (Jacobsen a. Neumeister, *B.* 15, 600).

CHLORO-BROMANILIC ACID *v.* CHLORO-BROMO-DI-OXY-QUINONE.

CHLORO-BROMO-ACETIC ACID $CHClBr.CO_2H$. [201°]. Prepared by heating chloro-acetic acid (1 mol.) with bromine (1 mol.) at 160° (Cech a. Steiner, *B.* 8, 1174). Pungent liquid; attacks the skin. Its salts are v. sol. water.

Ethyl ether EtA'. (c. 162°). Smells like peppermint; partially decomposed on boiling.

Amide $CHClBr.CONH_2$: [126°]; needles.

Chloro-di-bromo-acetic acid $CClBr_2.CO_2H$. [89°]. (233°). Formed by oxidation of the corresponding aldehyde with HNO_3 (Neumeister, *B.* 15, 603). Trimetric plates (from conc. HNO_3). By alkalis it is split up into CO_2 and chloro-di-bromo-methane.

Salts.—KA' 2aq: glistening soluble prisms.—PbA'_2 aq, sparingly soluble slender needles.

Ethyl ether A'Et: (203°); liquid.

Amide $CClBr_2.CONH_2$: [127°]; small transparent dimetric tables; v. sol. ether and chloroform, sl. sol. benzene and CS_2. Formed together with $CHClBr_2$ by the action of dry NH_3 upon di-chloro-tetra-bromo-acetone $CClBr_2.CO.CClBr_2$ dissolved in ether (Levy a. Jedlička, *B.* 20, 2320).

Di-chloro-bromo-acetic acid $CCl_2Br.CO_2H$. [64°]. (215°). Formed by oxidation of the corresponding aldehyde with HNO_3 (Neumeister, *B.* 15, 602). Large prisms. V. sol. water and alcohol. By boiling with alkalis it is split up into di-chloro-bromo-methane and CO_2.

Salts.—KA' 3aq: long trimetric prisms.—NaA' 5aq: large tables, sol. water, alcohol, and ether. — *NH_4A': long fine needles.—PbA'_2 aq: sparingly soluble glistening prisms.

Ethyl ether A'Et: (189°); liquid.

Amide [139°]; (254°); tables. Sol. alcohol and ether; insol. chloroform.

CHLORO-DI-BROMO-ACETIC ALDEHYDE $CClBr_2.CHO$. *Chlorobromal.* (149°). S.G. ^{15} 2·2793. Prepared by the action of bromine on chloro-acetal $CH_2Cl.CH(OEt)_2$. Liquid. By treatment with KOH it gives chloro-di-bromo-methane (Jacobsen a. Neumeister, *B.* 15, 600).

Hydrate $CClBr_2.CH(OH)_2$. *Chloro-di-bromo-acetic orthaldehyde.* [52°]; small prisms.

Alcoholate $CClBr_2.CH(OH)(OEt)$: [46°]; long needles.

Combination with Acetamide [158°].

Di-chloro-bromo-acetic aldehyde $CCl_2Br.CHO$. *Bromochloral.* (126°). S.G. ^{15} 1·9176. Prepared by the action of bromine on di-chloro-acetal $CHCl_2.CH(OEt)_2$ (Jacobsen a. Neumeister, *B.* 15, 600). Colourless pungent liquid. On heating with H_2SO_4 it gives bromochloralide $C_5H_2Cl_4Br_2O_3$ [122°].

Hydrate $CCl_2Br.CH(OH)_2$. *Di-chloro-bromo-acetic orthaldehyde.* [51°]. Colourless trimetric plates. Sol. water, alcohol, and ether.

Alcoholate $CCl_2Br.CH(OH)(OEt)$: [43°]; slender needles.

CHLORO-BROMO-ACETO-ACETIC ETHER $C_6H_8ClBrO_3$. From chloro-aceto-acetic ether and Br; or from bromo-aceto-acetic ether and Cl (Merves, *A.* 245, 62). Oil. NaOEt gives bromo-acetic ether.

Chloro-di-bromo-aceto-acetic ether $C_6H_6ClBr_2O_3$. From di-bromo-aceto-acetic ether and Cl in diffused daylight (M.). NaOEt forms chloro-bromo-acetic ether (162°).

Di-chloro-bromo-aceto-acetic ether $C_6H_6Cl_2BrO_3$. From bromo-aceto-acetic ether and Cl (M.). NaOEt forms di-chloro-acetic ether.

Di-chloro-di-bromo-aceto-acetic ether $C_6H_8Cl_2Br_2O_3$ *i.e.* $CHBr_2.CO.CCl_2.CO_2Et$(?) S.G. $\frac{19}{14}$ 1·956. Formed by bromination of di-chloro-aceto-acetic ether. Oil. On saponification by heating with HCl it yields di-chloro-di-bromo-acetone (Conrad a. Guthzeit, *B.* 16, 1551).

CHLORO-BROMO-ACETONE C_2H_4ClBrO *i.e.* $CH_2Cl.CO.CH_2Br$ or  $CH_2Cl.\overbrace{CH.CHBr}^{O}$. [35°]. (c. 179°). Obtained from epichlorhydrin  $CH_2Cl.\overbrace{CH.CH_2}^{O}$ by treatment with HBr and oxidation of the resulting $CH_2Cl.CH(OH).CH_2Br$ (Theegarten, *B.* 6, 897, 1276). Pungent crystals, sl. sol. water; v. sol. alcohol and ether. Forms a crystalline compound with $NaHSO_3$ (Theegarten; *cf.* Cloez, *A. Ch.* [6] 9, 145).

Chloro-tri-bromo-acetone $C_3H_2Br_3ClO$. [50°]. Prepared by heating dichloro-dibromo-acetone with HBr; or dichlorhydrin (1 mol.) with bromine (3 mols.) and water at 110° (Claus a. Lindhorst, *B.* 13, 1210). Trimetric prisms: *a:b:c* = ·7124:1:2.

Chloro-tri-bromo-acetone $C_3H_2ClBr_3O$. *Tri-bromo-epichlorhydrin.* Prepared by treating epichlorhydrin (1 mol.) with bromine (1 mol.) at 100°. Pungent liquid; heavier than water; cannot be distilled even *in vacuo.* On shaking with water it forms a hydrate $C_3H_2ClBr_3O$ 4aq [55°] (Grimaux a. Adam, *Bl.* [2] 33, 257; *cf.* Cloez, *A. Ch.* [6] 9, 145).

Chloro-tri-bromo-acetone $C_3H_2ClBr_3O$ *i.e.* $CBr_3.CO.CH_2Cl$. (215°). S.G. 2·27. From chloro-acetone and bromine at 100° (Cloez). Pungent liquid. Forms hydrates $C_3H_2ClBr_3O$ 4aq (from water) and $C_3H_2ClBr_3O$ aq (from alcohol). Cold aqueous ammonia forms bromoform and chloro-acetamide.

Di-chloro-di-bromo-acetone $C_3H_2Cl_2Br_2O$ *i.e.*  $CHBrCl.\overbrace{CH.CBrCl}^{O}$ or $CHBrCl.CO.CHBrCl$. [−8°]. (135°) at 40 mm. From di-chloro-acetone (derived from epichlorhydrin) and bromine (Cloez). Does not combine with $NaHSO_3$. With water it forms long prisms of the hydrate $C_3H_2Cl_2Br_2O$ 4aq [54°]. Does not give off a chloro-bromo-methane when treated with ammonia.

Di-chloro-di-bromo-acetone $C_3H_2Cl_2Br_2O$ *i.e.*  $CBr_2Cl.\overbrace{CH.CHCl}^{O}$ or $CBr_2Cl.CO.CH_2Cl$ (141°) at 20 mm. Prepared by heating dichlorhydrin (1 mol.) with bromine (3 mols.) and ½ the volume of water to 110° until the colour of the Br has gone; the yield is theoretical (Claus a. Lindhorst, *B.* 13, 1209; *cf.* Carius, *A.* 155, 88; Grimaux a. Adam, *Bl.* [2] 32, 14; Cloez, *loc. cit.*). Forms a hydrate $C_3H_2Cl_2Br_2O$ 4aq, [56°], (140°–150°) at 20 mm. Not identical with the preceding (C.).

Di-chloro-di-bromo-acetone $CHCl_2.CO.CHBr_2$. (120°) at 25 mm. Formed by the action of bromine on ordinary di-chloro-acetone or Barbaglia's di-chloro-acetone (170°) (Cloez). It forms unstable hexagonal tables of $C_3H_2Cl_2Br_2O$ 4aq. Ammonia forms no chloro-bromo-methane. $HgCl_2$ gives tetra-chloro-acetone.

Di-chloro-di-bromo-acetone $C_3H_2Cl_2Br_2O$ or $CHCl_2.CO.CHBr_2$ (?) Formed by heating di-chloro-di-bromo-aceto-acetic ether with HCl (Conrad a. Guthzeit, *B.* 16, 1552). Colourless pungent liquid. Forms a hydrate $C_3H_2Cl_2Br_2O$ 4aq crystallising in large colourless six-sided tables. Is perhaps identical with the preceding.

Di-chloro-tetra-bromo-acetone $CClBr_2.CO.CClBr_2$. [79°]. Formed by the action of bromine upon *p*-di-chloro-*p*-di-oxy-quinone (chloranilic acid) $C_6Cl_2(OH)_2O_2$. Transparent monoclinic crystals (from acetic acid). Heated with baryta-water it yields chloro-di-bromo-methane $CHClBr_2$. Dry NH_3 gas converts it into chloro-di-bromo-acetamide $CClBr_2.CONH_2$, and chloro-di-bromo-methane. With phenyl-hydrazine it gives a mixture of chloro- and bromo-benzene (Levy a. Jedlička, *B.* 20, 2319; *cf.* Stenhouse, *A. Suppl.* 8, 17).

Tri-chloro-bromo-acetone $C_3H_2Cl_3BrO$ *i.e.* $CCl_3.CO.CH_2Br$. (190°). From tri-chloro-acetone and bromine at 100°. Very hygroscopic, forming hexagonal tables of the hydrate $C_3H_2Cl_3BrO$ 4aq [48°]. With ammonia it forms chloroform and bromo-acetamide (Cloez).

TRI-CHLORO-αβ-DI-BROMO-ACETYL-PROPIONIC ACID $C_5H_3Cl_3Br_2O_3$ *i.e.* $CCl_3.CO.CHBr.CHBr.CO_2H$. [98°]. From tri-chloro-acetyl-acrylic acid and Br in chloroform (Kekulé a. O. Strecker, *A.* 223, 188). Volatile with steam; may be sublimed; insol. cold water. Boiling lime-water splits it up into chloroform and inactive tartaric acid.

CHLORO-BROMO-ACRYLIC ACID $C_3H_2ClBrO_2$ *i.e.* $CBrCl:CH.CO_2H$ (?) [70°]. S. 5·75 at 20°. Prepared by the action of HCl on bromo-propiolic acid at 0° (Mabery a. Lloyd, *Am.* 3, 127; Hill, *B.* 12, 660). Needles or prisms; may be sublimed. V. sol. alcohol and ether. Chlorine forms tri-chloro-bromo-propionic acid [84°] (Mabery, *Am.* 9, 1).

Salts.—KA'.—BaA'_2 2aq: flattened prisms. S. 14·15 at 20°.—CaA'_2 4aq: needles; v. e. sol. hot water.—AgA'.

(α)-Chloro-di-bromo-acrylic acid $C_2ClBr_2.CO_2H$ *i.e.* $CBr_2:CCl.CO_2H$ (?) [104°]. S. 5·7 at 20°. Prepared by the action of ClBr in chloroform on bromo-propiolic acid in the cold (Mabery a. Lloyd, *Am.* 6, 157). Triclinic prisms (from CS_2); v. sol. hot water, CS_2, and chloroform.

Salts.—AgA': trimetric plates (from water); not affected by light.—CaA'_2 $2\frac{1}{2}$aq: branching needles.—BaA'_2 3aq: flat prisms. S. 26 at 20°.

(β)-Chloro-di-bromo-acrylic acid $CBrCl:CBr.CO_2H$. [99°]. S. 2·5 at 20°. From chloro-tri-bromo-acrylic acid by adding baryta-water in the cold till alkaline (M. a. L.). Prisms (from CS_2); v. sol. alcohol, ether, and hot water.—BaA'_2 8aq: slender prisms. S. ·35 at 20°.—CaA'_2 4aq: branching needles.

Di-chloro-bromo-acrylic acid $C_2BrCl_2.CO_2H$ *i.e.* $CCl_2:CBr.CO_2H$(?) [78°-80°]. S. 6·9 at 20°. Obtained by the action of cold baryta-water on di-chloro-di-bromo-propionic acid obtained from αβ-di-bromo-acrylic acid and chlorine (Mabery, *Am.* 9, 8). Prisms; v. sol. alcohol and ether: sl. sol. cold CS_2.

Salts. — KA': slender needles.—AgA': slender needles.—BaA'_2 3aq: trimetric plates.—CaA'_2 4aq: pearly needles.

Di-chloro-bromo-acrylic acid $C_2BrCl_2.CO_2H$ *i.e.* $CClBr:CBr.CO_2H$(?) [85°]. S. 2·6 at 20°. Obtained by the action of cold baryta-water (1 mol.) on di-chloro-di-bromo-propionic acid (1 mol.) that has been prepared from bromine and αβ-di-chloro-acrylic acid (M.). Prisms; v. sol. alcohol and ether, m. sol. CS_2. This acid is possibly identical with the preceding.

Salts.—KA': pearly needles.—AgA': slender needles. — BaA'_2 3aq: trimetric plates.—CaA'_2 4aq: jagged plates.

CHLORO-BROMO-ALDEHYDE *v.* CHLORO-BROMO-ACETIC ALDEHYDE.

ω-DI-CHLORO-*m*-BROMO-AMIDO-ACETOPHENONE [5:2:1] $C_6H_3Br(NH_2).CO.CHCl_2$. [110°-120°]. Formed by boiling ωω*m*-tri-bromo-amido-acetophenone with HCl (Baeyer a. Bloem, *B.* 17, 967). Sublimable. Fine felted orange needles or long flat prisms. V. sol. alcohol, sl. sol. water. By boiling with dilute NaOH and exposure to the air it yields bromo-indigo.

CHLORO-BROMO-ANILINE $C_6H_3ClBr(NH_2)$ [2:4:1]. [69°]. Formed, together with *p*-bromo-aniline, by the action of tin and HCl on *p*-bromo-nitro-benzene (Hübner a. Alsberg, *A.* 156, 312; Fittig a. Büchner, *A.* 188, 14). Formed also by chlorinating *p*-bromo-aniline. Prisms; volatile with steam.—B'HCl.

Chloro-di-bromo-aniline $C_6H_2ClBr_2(NH_2)$ [6:4:2:1]. [95°]. Formed by bromination of *o*-chloro-aniline (Langer, *B.* 15, 1065; *A.* 215, 115). Long white needles (from benzoline); v. sol. boiling alcohol and ether.

Chloro-di-bromo-aniline $C_6H_2ClBr_2(NH_2)$ Formed by brominating *p*-chloro-aniline (Hofmann, *A.* 53, 38). White prisms, which melt in hot water; volatile with steam. Does not form salts.

Chloro-tri-bromo-aniline $C_6HClBr_3(NH_2)$ [3:2:4:6:1]. [124°]. Formed by bromination of *m*-chloro-aniline by Br in dilute HCl (Langer, *B.* 15, 1065; *A.* 215, 112). Thin white needles (from alcohol); v. sol. boiling alcohol and ligroïn.

Di-chloro-bromo-aniline $C_6H_2Cl_2Br(NH_2)$ [2:6:4:1]. [93·5°]. Formed by chlorinating *p*-bromo-aniline (Fittig a. Büchner, *A.* 188, 22). Does not unite with acids.

Di-chloro-tri-bromo-aniline $C_6Cl_2Br_3(NH_2)$ [3:5:2:4:6:1]. [219·5°]. From di-chloro-aniline $C_6H_3(NH_2)Cl_2$ [1:3:5] in dilute HCl by bromine-water (Langer, *A.* 215, 122). White needles (from alcohol). M. sol. boiling alcohol.

Tri-chloro-di-bromo-aniline $C_6Cl_3Br_2(NH_2)$ [2:4:6:3:5:1]. [238·5°]. From $C_6H_3(NH_2)Br_2$ [1:3:5] in acetic acid by Cl (Langer, *A.* 215, 118). White needles (from alcohol).

DI-CHLORO-BROMO-ANTHRACENE $C_{14}H_7Cl_2Br$. [168°]. Formed by heating di-chloro-anthracene tetra-bromide at 190° (Schwarzer, *B.* 10, 376). Small greenish-yellow laminæ; v. sol. benzene and chloroform.

Di-chloro-di-bromo-anthracene $C_{14}H_6Cl_2Br_2$. [252°]. From di-chloro-anthracene tetrabromide and alcoholic KOH (S.). Small yellow needles (from benzene); sl. sol. alcohol, v. sol. benzene.

Di-chloro-tetra-bromo-anthracene $C_{14}H_4Cl_2Br_4$. Formed by the action of alcoholic KOH upon di-chloro-di-bromo-anthracene-tetra-bromide (Hammerschlag, *B.* 19, 1107). Golden-yellow needles. Solid at 380°. V. sl. sol. all solvents. By CrO_3 and acetic acid it is oxidised to tetra-bromo-anthraquinone.

DI-CHLORO-DI-BROMO-ANTHRACENE-TETRA-BROMIDE $C_{14}H_6Cl_2Br_6$. [212°]. Glistening white needles (from acetic acid). Formed by combination of di-chloro-di-bromo-anthracene with bromine vapour. By alcoholic KOH it is converted into di-chloro-tetra-bromo-anthracene (Hammerschlag, *B.* 19, 1107).

***m*-CHLORO-BROMO-BENZENE** C_6H_4ClBr [1:3]. From *p*-chloro-aniline by bromination and elimination of NH_2 by the diazo-reaction (Körner, *J.* 1875, 326; *G.* 4, 305).

***p*-Chloro-bromo-benzene** C_6H_4ClBr [1:4]. [67°]. (196°). From *p*-bromo-aniline by displacement of NH_2 by Cl; or from *p*-chloro-aniline by displacing NH_2 by Br (Griess, *Tr.* 1864 [3] 702). Also by boiling *p*-chloro-benzene with bromine (Körner, *G.* 4, 342).

Chloro-tri-bromo-benzene $C_6H_2ClBr_3$ [1:2:4:6]. [80°] (S.); [82°] (L.). *Formation.*—1. By heating the perbromide of tri-bromo-diazo-benzene chloride (from tri-bromaniline) with glacial acetic acid (Silberstein, *J. pr.* [2] 27, 113).—2. From $C_6HClBr_3(NH_2)$ [123·5°], alcohol, and amyl nitrite at 100° (Langer, *A.* 215, 113; *B.* 15, 1065). *Properties.*—Long satiny needles. Insol. water, sl. sol. cold alcohol and glacial acetic acid, v. sol. hot alcohol, hot glacial acetic acid, ether, benzene and $CHCl_3$.

Di-chloro-di-bromo-benzene $C_6H_2Br_2Cl_2$. [67°] (Garzino, *G.* 17, 502).

Di-chloro-tri-bromo-benzene $C_6HCl_2Br_3$ [1:3:2:4:6]. [121°]. From $C_6(NH_2)Cl_2Br_3$ by treatment with amyl nitrite and alcohol (Langer, *A.* 215, 120; *B.* 15, 1332). Small thin needles (from alcohol).

Tri-chloro-di-bromo-benzene $C_6HCl_3Br_2$ [1:3:5:2:4]. [119°]. From $C_6(NH_2)Cl_3Br_2$ and amyl nitrite in alcohol (Langer, *A.* 215, 119). Slender needles. V. sol. boiling alcohol.

CHLORO-BROMO-BENZOIC ACID $C_7H_4ClBrO_2$ *i.e.* $C_6H_3ClBr.CO_2H$. [151°]. S. ·26 at 21°. Formed by adding bromine to a hot solution of silver *o*-chloro-benzoate (but not of the free acid) (Pfeifer, *B.* 5, 656). Slender needles (from water); may be sublimed.—KA′aq.—BaA′$_2$ 3aq.—CaA′$_2$ 2aq.

Chloro-bromo-benzoic acid $C_6H_3ClBr.CO_2H$. S. ·09 at 21°. From *m*-chloro-benzoic acid and bromine (P.). Slender needles.—BaA′$_2$ 2aq.

DI-CHLORO-DI-BROMO-BUTANE $C_4H_6Cl_2Br_2$ *i.e.* $CH_3.CHBr.CHBr.CHCl_2$. From Br and the di-chloro-butylene derived from crotonic aldehyde (Kekulé, *A.* 162, 98; Newbury, *Am.* 5, 113). Decomposes above 100°. Converted by boiling dilute K_2CO_3 into C_4H_6ClBrO (115°–120°).

CHLORO-DI-BROMO-BUTYL ALCOHOL $C_4H_7ClBr_2O$. Obtained by the union of bromine with chloro-butenyl (chloro-crotyl) alcohol which is itself got by reduction of tri-chloro-butyl alcohol (Garzarolli-Thurnlackh, *A.* 213, 378). HNO_3 oxidises it to chloro-di-bromo-butyric acid.

CHLORO-DI-BROMO-BUTYRIC ACID $C_4H_5ClBr_2O_2$ *i.e.* $CH_3.CHBr.CClBr.CO_2H$ (?) [92°]. From α-chloro-crotonic acid and Br (Sarnoff, *A.* 164, 105). Prisms, m. sol. cold, decomposed by hot water. Distillation, or treatment with zinc and HCl, converts it into chloro-crotonic acid.—PbA′$_2$.—AgA′.

Chloro-tri-bromo-butyric acid $C_4H_4ClBr_3O_2$. [140°]. Formed by oxidising the corresponding aldehyde with fuming HNO_3 (Pinner, *B.* 8, 1324). Small plates.

CHLORO-DI-BROMO-BUTYRIC ALDEHYDE $C_4H_5ClBr_2O$ *i.e.* $CH_3.CHBr.CClBr.CHO$. From Br and α-chloro-crotonic aldehyde in the cold (Pinner, *B.* 8, 1322). Oil; with water it slowly forms a solid hydrate or orthaldehyde $C_4H_5ClBr_2(OH)_2$.

Chloro-tri-bromo-butyric aldehyde $C_4H_4ClBr_3O$. Formed by warming α-chloro-crotonic aldehyde with bromine (P.). Oil. Forms a hydrate or orthaldehyde $C_4H_4ClBr_3(OH)_2$ [78°] crystallising in slender needles.

Di-chloro-di-bromo-butyric aldehyde $CH_2Cl.CHBr.CClBr.CHO$. [c. –78°]. From αγ-di-chloro-crotonic aldehyde and Br in the cold (Natterer, *M.* 4, 540). Combines with $NaHSO_3$. It forms a crystalline hydrate or orthaldehyde $CH_2Cl.CHBr.CClBr.CH(OH)_2$ [72°].

CHLORO-BROMO-CAMPHOR *v.* CAMPHOR.

CHLORO-DI-BROMO-*n*-CUMENE $C_6H_5.CHBr.CHBr.CH_2Cl$. [96·5°]. From styryl chloride and Br. Tables (from ether).

TRI-CHLORO-BROMO-CYMENE $C_6Cl_3Br(CH_3)(C_3H_7)$(?) [65°]. From sodium tri-chloro-cymene sulphonate and bromine-water (Kelbe, *B.* 16, 619). Needles.

CHLORO-PENTA-BROMO-DECYLENE $C_{10}H_{14}ClBr_5$. From Br and menthyl chloride (Oppenheim, *A.* 130, 177).

***s*-CHLORO-BROMO-ETHANE** $CH_2Cl.CH_2Br$. *Ethylene chloro-bromide.* (108°). S.G. ^{0} 1·79; ^{10} 1·70.

Formation.—1. From *s*-chloro-iodo-ethane and Br (Henry, *A.* 156, 14).—2. From ethylene di-bromide and $HgCl_2$ (Montgolfier a. Giraud, *Bl.* [2] 33, 12).—3. From $CH_2Cl.CH_2.OH$ and Br at 130° (Demole, *B.* 9, 556).—4. From ethyl bromine by chlorination (Lescœur, *Bl.* [2] 29, 484).

Preparation.—1. Bromine (500 g.) is dissolved in 700 c.c. HCl mixed with 700 c.c. water, cooled with ice, and treated with chlorine as soon as the temperature of the liquid has fallen to 2°. The chlorine is passed in, with frequent shaking, until the colour of the bromine has disappeared. Ethylene is then passed in, and the oil washed, dried, and distilled. It boils at 107°-109°. If it boils at 109°-111° it contains ethylene bromide (M. Simpson, *Pr.* 27, 119; J. W. James, *J. pr.* [2] 26, 380; *C. J.* 43, 37).—2. $C_2H_4Br_2$ is gently warmed with $SbCl_3$, the product poured into strong HCl, and the oil washed with very dilute NaOH and distilled (Lössner, *J. pr.* 121, 421; James, *C. J.* 35, 806).

Reactions.—1. Acts upon boiling alcoholic KCNS forming $C_2H_4Cl(CNS)$.—2. Alcoholic KOH gives KBr and chloro-ethylene.

u-Chloro-bromo-ethane $CH_3.CHClBr$. *Ethylidene-chloro-bromide.* (82°) (R.); (83° i. V.) (S.). S.G. ^{14} 1·61 (R.); ^{10} 1·67.

Formation.—1. From bromo-ethylene and conc. HClAq at 100° (Reboul, *A.* 155, 215).—2. By brominating ethyl chloride in sunlight (Staedel, *B.* 11, 1739; Denzel, *A.* 195, 193).—3. By chlorinating ethyl bromide (Lescœur, *Bl.* [2] 29, 483).

Properties.—Oil. Converted by alcoholic KOH into KBr and bromo-ethylene. Ag_2O gives aldehyde.

Chloro-di-bromo-ethane $CH_3.CBr_2Cl$. (124° i. V.). S.G. ^{22} 2·134. A product of bromination of ethyl chloride in sunlight (Staedel, *B.* 11, 1739; Denzel, *A.* 195, 196). Liquid. Converted by alcoholic KOH into $CH_2{:}CClBr$.

Chloro-di-bromo-ethane $CH_2Br.CHClBr$. (163° i. V.). S.G. ^{16} 2·268. From chloro-ethylene and Br (Hugo Müller, *A. Suppl.* 3, 287). From chloro-bromo-iodo-ethane and Br (Henry, *Bl.* [2] 42, 263). Also from EtCl and Br in sunlight (S.; D.). Oil. Alcoholic KOH gives $CH_2{:}CClBr$. With $SbCl_5$ it gives $CH_2Br.CHCl_2$.

Chloro-di-bromo-ethane $CH_2Cl.CHBr_2$. From crude chloro-bromo-iodo-ethane and Br (H.). Alcoholic KOH gives $CH_2{:}CBr_2$ (89°) and $CH_2{:}CBrCl$ (63°).

Chloro-tri-bromo-ethane $CH_2Br.CClBr_2$. (201° i. V.) at 735 mm. S.G. ^{16} 2·602. Formed by the action of bromine on $CH_3.CClBr_2$, on ethyl chloride, on $CH_2Br.CHBrCl$, or on $CH_2{:}CClBr$ (S.; D.; H.). Gives $CHBr{:}CBrCl$ with alcoholic KOH. $SbCl_5$ forms $CH_2Br.CCl_3$.

Chloro-tetra-bromo-ethane $CHBr_2.CBr_2Cl$. *Chloro-acetylene tetra-bromide.* [83°]. (240°) at 735 mm. S.G. ^{16} 3·366. From EtCl and Br in sunlight (S.; D.). From chloro-acetylene and bromine (Wallach, *A.* 203, 89). Also from chloro-di-bromo-ethylene and Br (Mabery, *Am.* 5, 255). Pungent crystals; v. e. sol. alcohol and ether.

Chloro-penta-bromo-ethane C_2ClBr_5. [170°]. Prepared by the action of bromine on chloro-tribromo- and chloro-tetrabromo-ethane (Denzel, *B.* 12, 2207).

Di-chloro-bromo-ethane $CH_3.CCl_2Br$. (99° i. V.). S.G. ^{12} 1·752. Formed by brominating ethylidene chloride in sunlight (S.; D.). Liquid.

Di-chloro-bromo-ethane $CHCl_2.CH_2Br$. (138°). S.G. 1·859. From $CHCl_2.CH_2OH$ and PBr_3 (Lacre, *C. R.* 104, 1186). From $CHBr_2.CH_2Br$ (Henry, *C. R.* 97, 1491; *Bl.* [2] 42, 262), or $CHClBr.CH_2Br$ and $SbCl_5$. Converted by alcoholic KOH into $CH_2{:}CCl_2$.

Di-chloro-bromo-ethane $CHClBr.CH_2Cl$. (140° cor.). S.G. $\frac{15}{15}$ 1·8885; $\frac{25}{25}$ 1·8542. M.M. 10·995 at 21·6°. Formed by gradually adding bromo-ethylene to chloroform through which a current of chlorine is passing (Perkin, *C. J.* 45, 535).

According to Lescœur (*Bl.* [2] 29, 485) three isomeric di-chloro-bromo-ethanes are formed by chlorinating ethyl bromide, viz.: (1). (137°); S.G. ^{0} 1·88,—(2). (151°); S.G. ^{0} 1·998,—(3). (c. 160°); S.G. ^{0} 2·118.

Di-chloro-di-bromo-ethane $CHCl_2.CHBr_2$. *Acetylene di-chloro-di-bromide.* (195°–200°). S.G. ^{12} 2·391. From acetylene dibromide and $SbCl_5$ in the cold (Sabanejeff, *A.* 216, 256). Also from acetylene, Br (31 g.), and (120 g. of) aqueous HClO. *Reactions.*—1. Converted by Zn and alcohol into chloro-bromo-ethylene (*q. v.*).—2. Boiled 6 hours with alcoholic KOAc it forms $CHBr{:}CCl_2$ [114°–116°].

s-Di-chloro-di-bromo-ethane $CHClBr.CHClBr$. *Acetylene di-chloro-di-bromide.* (190°–195°). From bromine and acetylene di-chloride; or from chlorine and acetylene di-bromide (Sa.). Gives, with zinc and alcohol, acetylene dichloride (50°–60°).

Di-chloro-di-bromo-ethane $CH_2Br.CBrCl_2$. (177°). S.G. $\frac{16}{4}$ 2·270. From $CH_3.CHCl_2$ and Br in sunlight (S.; D.).

Di-chloro-tri-bromo-ethane $CHBr_2.CBrCl_2$. (215°–220°). From $CH_3.CHCl_2$ and Br in sunlight (S.; D.).

Di-chloro-tetra-bromo-ethane $C_2Cl_2Br_4$ *i.e.* $CBr_3.CCl_2Br$. [180°]. Colourless crystals. Prepared by the action of bromine on $CH_2Br.CCl_2Br$ (Denzel, *B.* 12, 2207).

Tri-chloro-bromo-ethane $CCl_3.CH_2Br$. (152°). S.G. $\frac{0}{0}$ 1·884. Formed by heating tri-chloro-ethane $CCl_3.CH_3$ with bromine at 160°; or by the action of $SbCl_5$ on $CCl_2Br.CH_2Br$ or $CClBr_2.CH_2Br$. Converted by alcoholic KOH into $CCl_2{:}CHBr$ (115°) (Henry, *C. R.* 98, 370).

Tri-chloro-di-bromo-ethane $CHBr_2.CCl_3$. (200°). S.G. ^{0} 2·317. From chloral and PCl_3Br_2 (Paterno, *J.* 1871, 512; *G.* 1, 590).

Tetra-chloro-di-bromo-ethane $CCl_2Br.CCl_2Br$. *Bromide of per-chloro-ethylene.* S.G. ^{21} 2·3. From C_2Cl_4 and Br in sunshine (Malaguti, *A. Ch.* [3] 16, 14). Tables (from alcohol). Begins to volatilise at 100° but decomposes at 200° into Br and C_2Cl_4.

Tetra-chloro-di-bromo-ethane $CCl_3.CClBr_2$. From penta-chloro-ethane and Br at 200° (Paterno, *G.* 1, 593). Also from $CHBr_2.CHBr_2$ and chlorine (Bourgoin, *Bl.* [2] 23, 4). Prisms (from alcohol); smells like camphor. May be sublimed, but decomposed by heat into chlorine and $C_2Cl_2Br_2$.

CHLORO-BROMO-ETHER *v.* CHLORO-BROMO-DI-ETHYL OXIDE.

s-CHLORO-BROMO-ETHYLENE C_2H_2ClBr *i.e.* $CHCl{:}CHBr$. *Acetylene chloro-bromide.* (82°). S.G. ^{0} 1·8157 (P.); 1·779 (S.); ^{20} 1·747 (S.). Bromine (2 mols.) is slowly added to acetylene chloro-iodide under water. The liberated iodine is removed by $Na_2S_2O_3$. The yield is small (Plimpton, *C. J.* 41, 393). Formed also by treating $CHCl_2.CHBr_2$ with zinc and alcohol (Sabanejeff, *A.* 216, 258). Liquid, does not polymerise. With alcoholic KOH it gives off an explosive gas, probably C_2HCl.

Chloro-bromo-ethylene $CH_2{:}CClBr$. (62°). From chloro-ethylene bromide $CH_2Br.CHClBr$ and KCy (Hugo Müller, *C. J.* 17, 420) or alcoholic KOH (Denzel, *A.* 195, 206; Demole a. Dürr, *B.* 11, 1602). Also from chloro-bromo-iodo-ethane (from C_2H_3Br and ICl) by alcoholic KOH (Henry, *Bl.* [2] 42, 263). Pungent odour, readily polymerises, becoming solid. Absorbs dry oxygen forming chloro-acetyl bromide and bromo-acetyl chloride.

Chloro-di-bromo-ethylene $CHBr{:}CBrCl$. (142°) at 735 mm. S.G. ^{16} 2·275 (S.). From chloro-tri-bromo-ethane $CH_2Br.CBr_2Cl$ and alcoholic KOH (Staedel, *B.* 11, 1740). Formed also by boiling chloro-tri-bromo-propionic acid with baryta-water (Mabery, *Am.* 5, 255). Liquid.

Chloro-tri-bromo-ethylene C_2ClBr_3 *i.e.* $CBr_2:CBrCl$. [84°]. (204°) at 730 mm. Prepared by the action of alcoholic KOH on chloro-tetra-bromo-ethane (Denzel, *B.* 12, 2208).

Di-chloro-bromo-ethylene $CHBr:CCl_2$. [114°–116°]. S.G. ^{15} 1·906. Formed by the action of alcoholic KOH on $CH_2Br.CBrCl_2$ (Denzel, *A.* 195, 206), or on $CCl_3.CH_2Br$ (Henry, *C. R.* 98, 370). Also from $CHBr_2.CHCl_2$ by alcoholic KOAc (Sabanejeff, *A.* 216, 261).

Di-chloro-di-bromo-ethylene $CCl_2:CBr_2$. (c. 194° ?). Prepared by the action of alcoholic KOH on di-chloro-tri-bromo-ethane $CHBr_2.CBrCl_2$ (Staedel, *B.* 11, 1740). Also from $CCl_3.CClBr_2$ by heating with aniline (Bourgoin, *Bl.* [2] 24, 116). Solidifies below 0°.

CHLORO-DI-BROMO-DI-ETHYL OXIDE $CHClBr.CHBr.OEt$. (170°–180°). From chloro-vinyl ethyl oxide and Br (Godefroy, *C. R.* 102, 869).

Tri-chloro-di-bromo-di-ethyl oxide $C_4H_5Cl_3Br_2O$ *i.e.* $CCl_2Br.CClBr.OEt$. [17°]. From tri-chloro-vinyl ethyl oxide and Br (Busch, *B.* 11, 446). With AgOAc it gives $C_2Cl_2Br(OAc)_2.OEt$ (180°–190°).

Hexa-chloro-tetra-bromo-di-ethyl oxide $C_4Cl_6Br_4O$. [96°]. Obtained by union of Br with chloroxethose C_4H_6O, a substance formed by the action of alcoholic K_2S on perchlorinated ether (Malaguti, *A. Ch.* [3] 16, 19).

DI-CHLORO-TETRA-BROMO-FLUORESCEÏN $C_{20}H_6O_5Cl_2Br_4$ *i.e.* $C_6H_2Cl_2(C_2O_2)(C_6HBr_2OH)_2O$. *Di-chloro-eosin.* Formed by brominating di-chloro-fluorescein (from resorcin and di-chloro-phthalic anhydride). The alkaline solution has a bluer shade than that of eosin (Le Royer, *A.* 238, 358).

Salt.—$C_{20}H_4K_2O_5Cl_2Br_4$.

CHLORO-BROMOFORM *v.* CHLORO-DI-BROMO-METHANE.

CHLORO-DI-BROMO-HEXANE $C_6H_{11}ClBr_2$. (219°). From hexenyl chloride and Br in CCl_4 (Destrem, *A. Ch.* [5] 27, 58).

Chloro-tetra-bromo-hexane $C_6H_9ClBr_4$. From Br and chloro-diallyl (Henry, *C. R.* 87, 171).

CHLORO-DI-BROMO-HEXYL ALCOHOL $C_6H_{11}ClBr_2O$. (c. 254°). S.G. ^{15} 1·99. From chloro-hexenyl alcohol (186°) and Br (Destrem, *A. Ch.* [5] 27, 58).

CHLORO-BROMHYDRIN *v.* CHLORO-BROMO-PROPYL ALCOHOL.

CHLORO-BROMO-HYDROQUINONE $C_6H_2ClBr(OH)_2$. [172°]. Formed by saponification of its di-acetyl-derivative produced by the action of acetyl bromide on chloro-quinone (Schulz, *B.* 15, 656). Formed also by the action of conc. HBrAq on chloro-quinone (Levy a. Schultz, *A.* 210, 160). Long needles. Sol. alcohol and ether, sl. sol. water. On oxidation it gives chloro-bromo-quinone [172°].

Di-acetyl-derivative $C_6H_2ClBr(OAc)_2$ [146°]. Short needles. Sol. alcohol and benzene.

Di-chloro-di-bromo-hydroquinone $C_6Cl_2Br_2(OH)_2$ [6:2:5:3:4:1]. [233°]. Formed by reduction of the corresponding quinone by $SnCl_2$ (Levy, *B.* 16, 1447; 18, 2369; Krause, *B.* 12, 54; Hantsch, *B.* 20, 2279). Monoclinic crystals: $a:b:c = 2·976:1:2·75$; $\beta = 77° 22'$.

Di-acetyl derivative $C_6Cl_2Br_2(OAc)_2$: [270°] (Levy, *B.* 18, 2369).

Tri-chloro-bromo-hydroquinone $C_6BrCl_3(OH)_2$ [229°]. From tri-chloro-bromo-quinone, HI, and phosphorus (Stenhouse, *A. Suppl.* 6, 219). Also from tri-chloro-quinone and conc. HBrAq (Levy a. Schultz, *A.* 210, 161). Monoclinic needles, $a:b:c = 2·915:1:2·671$; $\beta = 77° 40'$. Insol. water, sol. dilute alcohol.

CHLORO-BROMO-HYDROTHYMOQUINONE $C_6Me(C_3H_7)ClBr(OH)_2$ [3:6:2:5:4:1]. [63°] or [73°] (?). From chloro-thymoquinone $C_6HMe(C_3H_7)Cl(OH)_2$ [3:6:2:4:1] and HBr; or from bromo-thymoquinone $C_6HMe(C_3H_7)Br(OH)_2$ [3:6:2:5:1] [45°] and HCl. Obtained also by reducing chloro-bromo-thymoquinone [87°] with hydroxylamine (Schniter, *B.* 20, 1318). Needles.

Chloro-bromo-hydrothymoquinone $C_6Me(C_3H_7)ClBr(OH)_2$ [3:6:5:2:4:1]. [56°]. Formed by reducing chloro-bromo-thymoquinone [78°] with hydroxylamine (S.).

CHLORO-BROMO-HYDROTOLUQUINONE $C_6HMeClBr(OH)_2$. [123°] (anhy.). Formed by the action of HBr upon chloro-toluquinone. Crystals (containing aq). V. sol. alcohol and ether, m. sol. water and ligroïn, sl. sol. benzene and chloroform (Schniter, *B.* 20, 2286).

Chloro-bromo-hydrotoluquinone $C_6HMeClBr(OH)_2$. [121°] (anhy.). Formed by the action of HCl upon bromo-toluquinone. Long needles, containing aq (from hot water). Begins to sublime at 105° (Schniter, *B.* 20, 2287).

CHLORO-BROMO-IODO-ACRYLIC ACID $C_2ClBrI.CO_2H$. [116°]. Formed by heating bromo-propiolic acid with an ethereal solution of ICl (Mabery a. Lloyd, *Am.* 4, 96; *P. Am. A.* 17, 99). Monoclinic prisms (from water) melting at 110°; but at 116° when crystallised from CS_2; may be sublimed.—AgA′.—CaA'_2 aq: branching needles.—BaA'_2 $3\frac{1}{2}$aq: prisms; S. 25·4 at 20°.

Chloro-bromo-iodo-acrylic acid $C_3HClBrIO_2$. [129°]. Glistening colourless plates. V. sol. water, alcohol, and ether. Formed by the action of a chloroform solution of ClBr upon iodo-propiolic acid (Stolz, *B.* 19, 539).

CHLORO-BROMO-IODO-ETHANE C_2H_3ClBrI. (194°). S.G. ^{0} 2·53. Slowly formed by union of ICl with bromo-ethylene in the cold (Maxwell Simpson, *A.* 136, 142; Henry, *C. R.* 98, 680). Oil. Converted by alcoholic KOH into KCl (3 pts.), KI (1 pt.), bromo-iodo-ethylene $CH_2:CBrI$, and chloro-bromo-ethylene $CH_2:CClBr$. Hence the chloro-bromo-iodo-ethane must be a mixture of isomerides.

CHLORO-BROMO-IODO-PROPANE C_3H_5ClBrI. S.G. ^{2} 2·325. From chloro-iodo-propyl alcohol and PBr_5 (Henry, *B.* 4, 702; *cf.* 3, 851). Oil.

DI-CHLORO-BROMO-MESITYLENE $C_9H_9BrCl_2$ *i.e.* $C_6H_2Br(CH_3)(CH_2Cl)_2$. [76°]. From bromo-di-oxy-mesitylene by heating with conc. HClAq (Colson, *A. Ch.* [6] 6, 101). Readily gives off HCl in the air.

CHLORO-BROMO-METHANE CH_2ClBr. (68°). S.G. $\frac{0}{15}$ 1·991. V.D. 4·48. Formed by the action of excess of bromine on CH_2ClI (Henry, *C. R.* 101, 599). Oil; not decomposed by light.

Chloro-di-bromo-methane $CHClBr_2$. *Chloro-bromoform.* (119°) at 730 mm. (L. a. J.); (125°)

(J. a. N.). S.G. $\frac{15}{15}$ 2·445. V.D. 7·37 (for 7·22). Occurs in crude bromine (Dyson, *C. J.* 43, 36). Formed by boiling di-chloro-tetra-bromo-acetone $CClBr_2.CO.CClBr_2$ with baryta-water. Prepared also by the action of NaOH on chloro-di-bromo-acetic aldehyde (Jacobsen a. Neumeister, *B.* 15, 601). Colourless liquid, of sweetish odour (Levy a. Jedlička, *B.* 20, 2319).

Di-chloro-bromo-methane $CHCl_2Br$. (92°). S.G. $\frac{15}{15}$ 1·9254. *Bromochloroform.* Colourless liquid. Prepared by the action of NaOH on di-chloro-bromo-acetic aldehyde (Jacobsen a. Neumeister, *B.* 15, 601).

Tri-chloro-bromo-methane $CBrCl_3$. (104°). S.G. $\frac{0}{4}$ 2·0550 (Thorpe, *C. J.* 37, 203). C.E. (0°–10°) ·001089; (0°–100°) ·0012065. S.V. 108·43.

Formation.—1. By heating $CCl_3.SO_2Br$ with alcohol at 100° (Loew, *Z.* 1869, 624).—2. By bromination of chloroform (Paterno, *G.* 1, 593; Friedel a. Silva, *Bl.* [2] 17, 538).—3. By action of bromine on potassic tri-chloro-acetate at 120° (van 't Hoff, *B.* 10, 678).

Properties.—Liquid, smelling like carbon tetrachloride.

CHLORO-BROMO-METHANE SULPHONIC ACID. Barium salt $(CHClBr.SO_3)_2Ba$. From chloro-sulpho-acetate of barium and bromine (Andreasch, *M.* 7, 170). Satiny plates.

CHLORO-BROMO-METHYL-ETHYL-GLYOXALINE $C_6H_8ClBrN_2$ *i.e.* $C_3ClBr(CH_3)(C_2H_5)N_2$. *Chloro-bromo-oxal ethyline.* From chloro-methyl-ethyl glyoxaline by treatment with Br in CS_2 followed by boiling water (Wallach, *A.* 214, 290; *B.* 10, 1193). Oil with narcotic odour. Solidifies with difficulty. Sl. sol. water. Not volatile. With Br it forms $C_6H_8ClBrN_2Br_2HBr$.

Salts.—$B'HCl$: prisms.—$(B'HCl)_2PtCl_4$.—B'_2AgNO_3.

CHLORO-BROMO-NAPHTHALENE $C_{10}H_6ClBr$ [1:4]. [115°]. From (α)-naphthylamine *p*-sulphonic acid by conversion into bromo-naphthalene sulphonic acid, and treatment of the latter with PCl_5 (Clève, *Bl.* [2] 26, 540).

Chloro-bromo-naphthalene $C_{10}H_6ClBr$. [119°]. Formed, together with the following, by the action of Br (1 mol.) on (α)-chloro-naphthalene (1 mol.), or of Cl on (α)-bromo-naphthalene (Guareschi a. Biginelli, *G.* 16, 152; *C. C.* 1887, 518). Thin plates. Oxidised by CrO_3 to chloro-phthalic acid [184°]. Possibly identical with the preceding.

Chloro-bromo-naphthalene $C_{10}H_6ClBr$. [67°]. (303° uncor.). Prepared as above. Needles (by sublimation). CrO_3 in acetic acid gives chloro-bromo-naphthoquinone [167°] and chloro-bromo-phthalide.

Di-chloro-bromo-naphthalene $C_{10}H_5Cl_2Br$. [80°]. From di-chloro-naphthalene [38°] and Br in the cold (Laurent). Slender needles.

The following chloro-bromo-naphthalenes described by Laurent (*A. Ch.* 49, 218; 52, 275) are insufficiently characterised: $C_{10}H_4Cl_2Br_2$ (two), $C_{10}H_4Cl_3Br$ (three), and $C_{10}H_3Cl_3Br_2$ (two).

The following compounds are probably mixtures or molecular compounds: (*a*) $C_{20}H_9Cl_4Br_3$. [76°]. From di-chloro-naphthalene [38°] and Br followed by alcoholic KOH (Faust a. Saame, *A.* 160, 69). Needles (from ether-alcohol). (*b*) $C_{20}H_9Cl_4Br_3$. [78°]. From di-chloro-naphthalene [68°] by successive treatment with Br and alcoholic KOH (F. a. S.).

CHLORO-BROMO-NAPHTHALENE TETRABROMIDE $C_{10}H_6ClBr_5$. [110°]. From chloro-naphthalene and Br (Laurent). Triclinic columns.

CHLORO-DI-BROMO-NAPHTHALENE TETRA-CHLORIDE $C_{10}H_5ClBr_2Cl_4$. [150°]. From di-bromo-naphthalene tetra-chloride and chlorine. Triclinic columns, sl. sol. ether.

CHLORO-BROMO-NAPHTHOQUINONE $C_{10}H_4ClBrO_2$. [167°]. From chloro-bromo-naphthalene [67°] by CrO_3 in HOAc (Guareschi, *C. C.* 1887, 518).

CHLORO-BROMO-NITRO-ANILINE $C_6H_4ClBrN_2O_2$ *i.e.* $C_6H_2ClBr(NO_2)(NH_2)$ [4:6:2:1]. [106°]. From chloro-nitro-aniline in HClAq by bromine-vapour (Körner, *J.* 1875, 352; *G.* 4, 305). Orange-yellow needles.

CHLORO-BROMO-NITRO-BENZENE $C_6H_3ClBr(NO_2)$ [1:3:5]. [82·5°]. From the preceding by diazo- reaction (Körner, *G.* 4, 377). Laminæ.

Chloro-bromo-nitro-benzene $C_6H_3ClBr(NO_2)$ [1:4:2]. [69°]. From *p*-chloro-bromo-benzene and HNO_3 (K.).

Chloro-bromo-nitro-benzene $C_6H_3ClBr(NO_2)$ [1:3:4]. [49·5°]. From chloro-nitro-aniline [123°] by displacing NH_2 by Br (K.). With alcoholic NH_3 at 160° it regenerates the chloro-nitro-aniline.

TRI-CHLORO-DI-BROMO-NITRO-ETHANE $CCl_2Br.CClBr(NO_2)$. From $CCl_2{:}CCl(NO_2)$ and Br at 150°. Crystalline (Hoch, *J. pr.* [2] 6, 95).

CHLORO-BROMO-DI-NITRO-METHANE $CClBr(NO_2)_2$. Formed by passing chlorine into an aqueous solution of potassio-bromo-di-nitro-methane $CKBr(NO_2)_2$ (Losanitsch, *B.* 17, 848). Oil. V. sol. alcohol, insol. water. By caustic alkalis the Br atom is displaced by a metallic atom.

Chloro-di-bromo-nitro-methane $CClBr_2(NO_2)$. S.G. $\frac{15}{15}$ 2·421. Formed by simultaneous action of bromine and potash on $CClH_2(NO_2)$ (Tscherniak, *B.* 8, 610). An oil, insol. potash, volatile with steam.

CHLORO-BROMO-NITRO-PHENOL $C_6H_2ClBr(NO_2)OH$ [4:2:6:1]. [125°]. From (4,6,1)-chloro-nitro-phenol [87°] and Br in HOAc in the cold (Ling, *C. J.* 51, 787). Converted by Br and water at 100° into tetra-bromo-quinone. $C_6H_2ClBrNO_3K$: dark red needles.—BaA'_2 aq.—CaA'_2 2½aq.

Chloro-bromo-nitro-phenol $C_6H_2ClBr(NO_2)OH$ [2:4:6:1]. [120°]. Formed by boiling (4,6,1)-chloro-nitro-phenol [87°] with Br and HOAc, an isomeric change taking place (L.). Formed also by chlorinating (4,6,1)-bromo-nitro-phenol [88°]. When heated with Br and water it gives chloro-tri-bromo-quinone.—$C_6H_2ClBrNO_3K$: red plates.—CaA'_2 7aq.

ω-TRI-CHLORO-*eso*-DI-BROMO-*eso*-DI-NITRO-DI-PHENYL-ETHANE

$CCl_3.CH(C_6H_3Br.NO_2)_2$.

[170°]. From $CCl_3.CH(C_6H_4Br)_2$ and fuming HNO_3 (Zeidler, *B.* 7, 1180). Needles (from alcohol).

CHLORO-BROMO-DI-OXY-(α)-NAPHTHOQUINONE DIHYDRIDE $C_{10}H_6ClBrO_4$ *i.e.*

$$C_6H_4\left\langle\begin{array}{l}CO.C(OH)_2\\ \quad\quad | \\ CO.CClBr\end{array}\right.$$

. [105°]. From bromo-oxy-a)-naphthoquinone and Cl in HOAc. Needles. xidation gives a body [141°] (Zincke a. Gerland, B. 20, 3216).

DI-CHLORO-DI-BROMO-TETRA-OXY-DIPHENYL $C_6HClBr(OH)_2.C_6HClBr(OH)_2$. 266°]. From di-chloro-tri-bromo-resorcin by uccessive treatment with $NaHSO_3$ and with in and HCl (Benedikt, *M.* 4, 227).

CHLORO-BROMO-DI-OXY-QUINONE $_6ClBr(OH)_2O_2$ [6:3:5:2:4:1] (Hantzsch a. Schnier, *B.* 20, 2279). From *m*-di-chloro-*m*-dibromo-quinone and aqueous KOH (Krause, *B.* 2, 54) or tri-chloro-bromo-quinone (Levy, *A.* 210, 168; *B.* 16, 1444; *B.* 18, 2370). Red leaflets (containing aq); may be sublimed—K_2A''2aq.—Na_2A''2aq.—Ag_2A''.

CHLORO-DI-BROMO-OXY-VALERIC ACID $C_5H_7ClBr_2O_3$. [169°]. Prepared by the addition of Br to chloro-oxy-angelic acid (Pinner a. Klein, *B.* 11, 1497). Sol. ether, insol. benzene.

CHLORO-DI-BROMO-PENTANE $C_5H_9ClBr_2$. From isoprene hydrochloride C_5H_8HCl and Br (Bouchardat, *C. R.* 89, 1217).

Di-chloro-di-bromo-pentane $CH_3.CHBr.CBrCl.CHCl.CH_3$. (c. 143°) at 31 mm. From di-chloro-amylene $CH_3.CH:CCl.CHCl.CH_3$ and bromine (Thurnlackh, *A.* 223, 161).

Di-chloro-di-bromo-pentane $C_5H_8Cl_2Br_2$. (230°–240°). From di-chloro-amylene (146°) and Br (Pinner, *A.* 179, 35).

DI-CHLORO-BROMO-PHENOL $C_6H_2Cl_2Br(OH)$. [68°]. (268°) (Garzino, *C. C.* 1887, 1546). From (4,2,1)-di-chloro-phenol and Br. *Tri-chloro-bromo-phenol* $C_6HCl_3Br(OH)$. Bromine converts tri-chloro-phenol [67°] into $C_6H_2Cl_3BrO$ [99°]. This is perhaps $C_6H_2Cl_3(OBr)$; it is converted, by heating under water, into an isomeride, which is probably $C_6HCl_3Br(OH)$ (Benedikt, *M.* 4, 235).

TRI-CHLORO-DI-BROMO-DI-PHENYL-ETHANE $CCl_3.CH(C_6H_4Br)_2$. [141°]. From bromo-benzene (1 pt.), chloral (2 pts.), and H_2SO_4 (Zeidler, *B.* 7, 1180). Silky needles.

Di-chloro-di-bromo-di-phenyl-ethylene $CCl_2:C(C_6H_4Br)_2$. [120°]. Formed by the action of alcoholic KOH upon the preceding body (Zeidler, *B.* 7, 1180). Needles (from alcohol).

β-CHLORO-α-BROMO-β-PHENYL-PROPIONIC ACID $C_6H_5.CHCl.CHBr.CO_2H$. [182°]. From α-bromo-β-oxy-β-phenyl-propionic acid and conc. HClAq at 100° (Glaser, *A.* 147, 92). Monoclinic tables (from chloroform). Boiling water forms HCl and bromo-oxy-phenyl-propionic acid, together with a little phenyl-acetic aldehyde and ω-bromo-styrene.

α-Chloro-β-bromo-β-phenyl-propionic acid $C_6H_5.CHBr.CHCl.CO_2H$. [185°]. From α-chloro-β-oxy-β-phenyl-propionic acid and conc. HBrAq at 60° (G.). Monoclinic tables (from chloroform). Boiling water gives ω-chloro-styrene and a little chloro-oxy-phenyl-propionic acid, and phenyl-acetic aldehyde.

α-Chloro-αβ-di-bromo-β-phenyl-propionic acid $C_6H_5.CHBr.CBrCl.CO_2H$. [136°]. From α-chloro-β-phenyl-propionic acid and Br (Forrer, *B.* 16, 855). Tables (from water).

CHLORO-BROMO-PHTHALIDE

$C_6H_2ClBr<\begin{matrix}CH_2\\CO\end{matrix}>O$. [179°]. Formed by oxidation of chloro-bromo-naphthalene [67°] with CrO_3 (Guareschi, *B.* 19, 1154).

CHLORO-BROMO-PICRIN *v.* CHLORO-DI-BROMO-NITRO-METHANE.

ω-CHLORO-α-BROMO-PROPANE C_3H_6ClBr *i.e.* $CH_3.CHBr.CH_2Cl$. *Propylene chloro-bromide.* (120°). Formed in small quantity, together with $CH_2Br.CH_2.CH_2Cl$ by treating allyl chloride with fuming HBr (Reboul, *A. Ch.* [5] 14, 487). Converted by alcoholic KOH into HCl and bromo-propylene.

α-Chloro-ω-bromo-propane $CH_3.CHCl.CH_2Br$. (120°). S.G. ^{0} 1·585. V.D. 5·52 (calc. 5·45). From propylene bromide by boiling with $HgCl_2$ (Friedel a. Silva, *Bl.* [2] 17, 532). Alcoholic KOH converts it into chloro-propylene (25°–30°).

Chloro-bromo-propane C_3H_6ClBr. (119°). From ClBr and C_3H_6 (Maxwell Simpson, *Pr.* 27, 119). Probably a mixture of the two preceding bodies.

ω-Chloro-β-bromo-propane $CH_2Br.CH_2.CH_2Cl$. *Tri-methylene chloro-bromide.* (142°). S.G. ^{0} 1·63. From tri-methylene bromide and $HgCl_2$. It is also the chief product of the union of HBr with allyl chloride (Reboul). Boiling alcoholic KOH gives ethyl-allyl oxide.

α-Chloro-α-bromo-propane $CH_3.CClBr.CH_3$. *Acetone chloro-bromide.* (c. 95°). S.G. ^{21} 1·474. From α-chloro-propylene $CH_3.CCl:CH_2$ and cold conc. HBrAq (Reboul, *A. Ch.* [5] 14, 482). Alcoholic KOH gives α-chloro-propylene and allylene.

ω-Chloro-ω-bromo-propane $CH_3.CH_2.CHClBr$. (111°). S.G. ^{20} 1·59. From ω-chloro-propylene $CH_3.CH:CHCl$ and HBr (R.). Alcoholic KOH gives $CH_3.CH:CHCl$.

Chloro-di-bromo-propane $C_3H_5ClBr_2$. (198°). From allyl bromide and ClBr. They unite slowly in the cold (Maxwell Simpson, *Pr.* 27, 119).

ω-Chloro-ωα-di-bromo-propane $CH_3.CHBr.CHClBr$ (177° cor.). From $CH_3.CH:CHCl$ and Br (Reboul, *Bl.* [2] 26, 278).

α-Chloro-ωα-di-bromo-propane $CH_3.CClBr.CH_2Br$. (170°). S.G. ^{0} 2·064 (Friedel, *A.* 112, 237). From $CH_3.CCl:CH_2$ and Br (F. a. S.; R.). With alcoholic KOH it gives C_3H_4ClBr and ethyl-propargyl oxide $CH{:}C.CH_2O.Et$ (Oppenheim, *A. Suppl.* 6, 372).

ω-Chloro-αβ-di-bromo-propane $CH_2Br.CHBr.CH_2Cl$. (195°) (O.); (203°) (R.). S.G. ^{0} 2·085 (R.). From allyl chloride and Br (O.). Also from epichlorhydrin

$\overset{\overbrace{\quad O \quad}}{CH_2.CH}.CH_2Cl$

and PBr_3 or PCl_3Br_2 (Reboul, *A. Suppl.* 1, 230; Darmstädter, *A.* 152, 320). Solid KOH gives $CH_2:CBr.CH_2Cl$. Alcoholic KOH gives rise to $CH{:}C.CH_2.OEt$.

α-Chloro-ωβ-di-bromo-propane $CH_2Br.CHCl.CH_2Br$. (200°). From glycerin dibromhydrin and PCl_5 (Berthelot a. de Luca, *J. pr.* 72, 317).

Chloro-tri-bromo-propane $C_3H_4ClBr_3$. (238°). S.G. ^{14} 2·39. From chloro-bromo-propylene (from glycide) and Br (Reboul, *A. Suppl.* 1, 231).

Di-chloro-bromo-propane $C_3H_5Cl_2Br$. (180°–187°). From allyl bromide and ClBr at 100° (M. Simpson, *Pr.* 27, 119).

ωβ-Di-chloro-α-bromo-propane $CH_2Cl.CHBr.CH_2Cl$. (176°). From *s*-dichlorhydrin and PBr_3 (Berthelot a. de Luca, *J. pr.* 17, 317).

ωα-Di-chloro-β-bromo-propane $CH_2Cl.CHCl.CH_2Br$. From $CH_2Cl.CH(OH).CH_2Br$ and PBr_5.

Di-chloro-bromo-propane $C_3H_4Cl_2Br$. (156°–160°). From bromo-propylene and chlorine (Linnemann, *A.* 138, 123).

ωα-Di-chloro-αβ-di-bromo-propane $CH_2Cl.CClBr.CH_2Br$. (205°). S.G. $\frac{0}{0}$ 2·161. From $CH_2Cl.CCl:CH_2$ and Br (Friedel a. Silva, *C. R.* 74, 805; 75, 81; *Bl.* [2] 17, 386).

ωβ-Di-chloro-αβ-di-bromo-propane $CH_2Cl.CHBr.CHClBr$. (221°) (F. a. S.); (212°) (Hartenstein, *J. pr.* [2] 7, 313). S.G. $\frac{0}{0}$ 2·19 (F. a. S.); $\frac{17\cdot5}{}$ 2·083 (H.). From $CH_2Cl.CH:CHCl$ and Br (R.; F. a. S.; H.).

ωα-Di-chloro-ωα-di-bromo-propane $CH_3.CClBr.CHClBr$. (189°). From allylene di-chloride and Br (F. a. S.; Pinner, *A.* 179, 44). Alcoholic KOH gives $C_3H_3Cl_2Br$ (143°).

Di-chloro-tri-bromo-propane $C_3H_3Cl_2Br_3$. [207°]. From di-chloro-bromo-propylene (143°) and Br (P.). Alcoholic KOH re-converts it into $C_3H_3Cl_2Br$.

β-CHLORO-α-BROMO-PROPIONIC ACID $CH_2Cl.CHBr.CO_2H$. [37°]. (c. 213°). Formed by the action of HNO_3 on the product of the union of BrOH with allyl chloride (Henry, *B.* 7, 757).

α-Chloro-β-bromo-propionic acid $CH_2Br.CHCl.CO_2H$. [37°]. (c. 213°). Formed similarly by oxidising the product of the union of ClOH with allyl bromide (H.).

Chloro-tri-bromo-propionic acid $C_2HClBr_3.CO_2H$. [103°]. From chloro-bromo-acrylic acid [70°] and Br (1 mol.) by heating for 2 hours at 100°; the yield is 70 p.c. (Mabery a. Weber, *Am.* 4, 104; 5, 255; *P. Am. A.* 17, 106). Triclinic prisms (from CS_2); v. sol. alcohol and ether. Boiling baryta-water forms C_2HClBr_2; cold baryta-water gives chloro-di-bromo-acrylic acid.—KA′aq.—CaA′$_2$.—BaA′$_2$: S. 23 at 20°.

Di-chloro-di-bromo-propionic acid $C_2HCl_2Br_2.CO_2H$. [95°]. Prepared by the combination of di-chloro-acrylic acid [86°] by heating with bromine at 100° for several hours (Hill a. Mabery, *P. Am. A.* 17, 140; *Am.* 4, 267; *B.* 14, 1679). Triclinic prisms, $a:b:c = 1\cdot023:1:1\cdot052$; $\alpha = 91°$; $\beta = 76° 31'$; $\gamma = 108° 52'$. V. sol. water, alcohol, and ether, m. sol. CS_2 or benzene.

Salts.—A′Ag: flat needles.—A′$_2$Ba: long easily soluble needles.

αβ-Di-chloro-ββ-di-bromo-propionic acid $CClBr_2.CHCl.CO_2H$. [100°]. Prepared by passing chlorine into di-bromo-acrylic acid at 100°; the yield is 96 p.c. (Mabery a. Nicholson, *Am.* 6, 166; *cf. Am.* 4, 270; *P. Am. A.* 17, 140; *B.* 14, 1680). Monoclinic prisms; v. e. sol. ether and alcohol, sol. hot $CHCl_3$ and CS_2, sl. sol. water.

Salts.—CaA′$_2$ 1½aq.—KA′2aq.

Tri-chloro-bromo-propionic acid $C_2HCl_3Br.CO_2H$. [84°]. Prepared by passing chlorine into a cold chloroform solution of chloro-bromo-acrylic acid in sunlight. The yield is 90 p.c. (Mabery, *Am.* 9, 1). Trimetric prisms; sl. sol. water, sol. ether, alcohol, and $CHCl_3$. Its salts are unstable.—KA′2aq: trimetric plates.—CaA′$_2$: oblique prisms.—BaA′$_2$: gummy.

Tetra-chloro-bromo-propionic acid $CBrCl_2.CCl_2.CO_2H$. [225°]. Prepared by passing chlorine into a solution of bromo-propiolic acid in chloroform, till the product crystallises out (Mabery, *Am.* 6, 155). Sl. sol. CS_2 and chloroform. Its salts are unstable.

α-CHLORO-β-BROMO-PROPYL ALCOHOL C_3H_6ClBrO *i.e.* $CH_2Br.CHCl.CH_2OH$. (197°). S.G. $\frac{0}{0}$ 1·764. From allyl bromide and HOCl (Henry, *B.* 7, 409, 758). Oxidation gives chloro-bromo-propionic acid (*v. supra*).

β-Chloro-α-bromo-propyl alcohol $CH_2Cl.CHBr.CH_2OH$. (197°). S.G. $\frac{11}{}$ 1·752. From allyl chloride and HOBr (H.). Oxidised by HNO_3 to chloro-bromo-propionic acid [37°], (215°).

Nitrate $CH_2(NO_3).CHBr.CH_2OH$. From the alcohol, HNO_3 and H_2SO_4. Oil.

α₁-chloro-α₂-bromo-isopropyl alcohol $CH_2Br.CH(OH).CH_2Cl$. *Chloro-bromhydrin.* (197°). S.G. $\frac{12}{}$ 1·740. From epichlorhydrin and HBr, or from epibromhydrin and HCl (Reboul, *A. Suppl.* 1, 225). Conc. KOH splits it up into HBr and epichlorhydrin. Oxidation gives chloro-bromo-acetone [35°] (Theegarten, *B.* 6, 1212). Also from epichlorhydrin and Br at 100° (Grimaux a. Adam, *Bl.* [2] 33, 257).

Ethyl ether $C_3H_5ClBr.OEt$. (187°). From epichlorhydrin  $\overbrace{CH_2.CH}^{O}.CH_2Cl$ and EtBr at 200° (Reboul a. Lourenço, *A.* 119, 238).

CHLORO-BROMO-PROPYL-BENZENE *v.* CHLORO-BROMO-CUMENE.

CHLORO-BROMO-PROPYLENE C_3H_4ClBr *i.e.* $CH_2:CCl.CH_2Br$. (121°). From α-chloro-allyl alcohol and PBr_3 (Henry, *C. R.* 95, 849).

Chloro-bromo-propylene $CHBr:CH.CH_2Cl$. (120°). S.G. $\frac{11}{}$ 1·63. From β-bromo-allyl alcohol and PCl_5 (Henry, *B.* 5, 453).

Chloro-bromo-propylene $CH_2:CBr.CH_2Cl$. (127°) (R.); (120°) (H.). S.G. $\frac{14}{}$ 1·69 (R.). From $CH_2Br.CHBr.CH_2Cl$ and solid KOH (Reboul, *A. Suppl.* 1, 230; Oppenheim, *A. Suppl.* 6, 374). From β-bromo-allyl alcohol and PCl_5 (H.).

Chloro-bromo-propylene $CH_3.CCl:CHBr$ (?) (105°). From $CH_3.CClBr.CH_2Br$ and alcoholic KOH (Friedel, *A.* 112, 237).

Di-chloro-bromo-propylene $CH_3.CCl:CClBr$(?) (143°). From allylene di-chloro-di-bromide and alcoholic KOH (Pinner, *A.* 179, 45). Br gives $C_3H_3Cl_2Br_3$ [207°].

CHLORO-BROMO-QUINONE $C_6H_2ClBrO_2$ [172°]. Formed by oxidation of chloro-bromo-hydroquinone (Schulz, *B.* 15, 656).

***m*-Di-chloro-*m*-di-bromo-quinone** $C_6Cl_2Br_2O_2$ [6:2:5:3:4:1]. [233°].

Formation.—1. Formed by the action of Br on di-chloro-phenylene di-imide (from bleaching-powder and *p*-phenylene-diamine hydrochloride) (Krause, *B.* 12, 53).—2. By bromination of *m*-di-chloro-quinone $C_6H_2Cl_2O_2$ [6:2:4:1] (Levy, *B.* 16, 1447).—3. By bromination of *p*-di-chloro-quinone $C_6H_2Cl_2O_2$ [6:3:4:1] (Levy, *B.* 18, 2367); in this case one of the Cl atoms must undergo transposition from the *p* to the *m*-position.—4. From hydroquinone, conc. HCl and Br (Benedikt, *M.* 1, 347).

Properties.—Monoclinic golden-brown tables; $a:b:c = 1\cdot445:1:3\cdot0286$; $\beta = 74° 31'$ (L.). Sl. sol. ether and alcohol, insol. water.

Reactions.—It is very readily reduced by hydroxylamine hydrochloride to the corresponding hydroquinone [234°], whose acetyl derivative melts at [270°] (Hantzsch a. Schniter, *B.* 20, 1279). By boiling with aqueous alkalis it is converted into a chloro-bromo-di-oxy-quinone $C_6ClBr(OH)_2O_2$.

Tri-chloro-bromo-quinone $C_6Cl_3BrO_2$. From tri-chloro-quinone and Br at 130° (Stenhouse, *A. Suppl.* 6, 219). Also from tri-chloro-bromo-hydroquinone and conc. HNO_3 (Levy a. Schultz, *A.* 210, 162). Golden monoclinic pyramids; $a:b:c = 1·48:1:2·95$; $\beta = 74°$ 41′. Sublimes at 160°. Dilute KOH gives chloro-bromo-di-oxy-quinone.

CHLORO-DI-BROMO-RESORCIN $C_6HBr_2Cl(OH)_2$. [105°]. Got by adding excess of bromine water to a solution of chloro-resorcin at 80°. Crystallises from water in silky needles (G. Reinhard, *J. pr.* [2] 17, 325).

Chloro-di-bromo-resorcin $C_6HBr_2Cl(OH)_2$. [86°]. From $C_6HBr_2Cl(OCl)(OBr)$ and $NaHSO_3$ (Benedikt, *M.* 4, 227).

Di-chloro-bromo-resorcin $C_6HBrCl_2(OH)_2$. [100°]. From Br and di-chloro-resorcin. Silky needles (from water) (R.).

Di-chloro-tri-bromo-resorcin $C_6HCl_2Br_3O_2$ *i.e.* $C_6HBr_2Cl(OCl)(OBr)$(?) Formed by adding Br (216 g.) dissolved in conc. HClAq (1,000 c. c.) to a solution of resorcin (50 g.) in water (2,000 c. c.) (B.). Yellow crystals. At 175° it gives crystalline $C_{12}H_2Cl_4Br_2O_4$ which is reduced by tin and HCl to di-chloro-di-bromo-tetra-oxy-diphenyl.

Tri-chloro-di-bromo-resorcin $C_6HCl_3(OBr)_2$. [100°]. Prepared by adding Br to tri-chloro-resorcin suspended in dilute HCl (B.). Small golden crystals. Gives off Br (1 mol.) on heating: Reduced by tin and HCl to tri-chloro-resorcin.

HEXA-BROMO-TRI-CHLORO-DI-THIENYL-ETHANE $CCl_3.CH(C_4Br_3S)_2$. [176°]. Formed by bromination of di-thienyl-tri-chloro-ethane (Peter, *B.* 17, 1343). White crystalline powder. V. sol. ether and chloroform, sl. sol. alcohol. Does not give the indophenine reaction.

CHLORO-BROMO-THYMOQUINONE $C_6MePrClBrO_2$ [1:4:5:2:3:6]. [78°]. Formed by bromination of *m*-chloro-thymoquinone $C_6HMePrClO_2$[1:4:5:3:6]. Yellow plates (Schniter, *B.* 20, 1319).

Chloro-bromo-thymoquinone $C_6MePrClBrO_2$ [1:4:2:5:3:6]. *p-Chloro-benzyl bromide.* [87°]. *Formation.*—1. By oxidation of the corresponding hydroquinone with Fe_2Cl_6.—2. By bromination of *o*-chloro-thymo-quinone $C_6HMePrClO_2$[1:4:2:3:6]. Golden-yellow plates (Schniter, *B.* 20, 1318).

***p*-CHLORO-ω-BROMO-TOLUENE** C_7H_6ClBr *i.e.* $C_6H_4Cl.CH_2Br$. [48·5°] (225°–230°). From *p*-chloro-toluene and Br (Jackson a. Field, *Am.* 1, 102). White needles (from alcohol); aromatic odour; volatile in the air.

ω-Chloro-*p*-bromo-toluene $C_6H_4Br.CH_2Cl$. *b-Bromo-benzyl chloride.* Obtained, mixed with an equivalent quantity of $C_6H_4Br.CH_2Br$, by brominating benzyl chloride (Errera, *G.* 17, 193). NaOEt converts it into $C_6H_4Br.CH_2.OEt$ (243°).

Di-chloro-bromo-toluene $C_7H_5Cl_2Br$. (280°–290°) (Jackson a. Field, *B.* 11, 905).

CHLORO-BROMO-TOLUQUINONE $C_6HMeClBrO_2$. [111°]. From the hydroquinone [123°], by oxidation. Thick needles. V. sol. ether, benzene, and chloroform; scarcely sol. water (Schniter, *B.* 20. 2287).

Chloro-bromo-toluquinone $C_6HMeClBrO_2$. [150°]. From the hydroquinone, [121°], by oxidation. Glistening yellow plates (from alcohol) (Schniter, *B.* 20, 2287).

TRI-CHLORO-DI-BROMO-DI-TOLYL-ETHANE $C_{16}H_{12}Cl_3Br_2$. [148°]. From tri-chloro-di-tolyl-ethane and Br in CS_2 (O. Fischer, *B.* 7, 1191).

DI-CHLORO-BROMO-VINYL-BENZOIC ACID $C_9H_5Cl_2BrO_2$ *i.e.* $CClBr:CCl.C_6H_4.CO_2H$. [174°]. From $C_6H_4<\begin{matrix}CO\\CClBr\end{matrix}>CClBr$ and alcoholic NaOH diluted with water (Zincke a. Fröhlich, *B.* 20, 2056). Needles.

Methyl ether MeA′. [82°].

CHLORO-BUTANE *v.* BUTYL CHLORIDE.

αα-Di-chloro-butane $CH_3.CCl_2.CH_2.CH_3$. (96°). From methyl ethyl ketone and PCl_5 (Bruylants, *B.* 8, 412). Dry KOH gives $CH:C.CH_2.CH_3$. Alcoholic KOH gives $CH_3.C:C.CH_3$ (Favorsky, *Bl.* [2] 45, 247).

ωω-Di-chloro-isobutane $(CH_3)_2CH.CHCl_2$. *Isobutylidene chloride.* (104°). S.G. $\frac{12}{}$ 1·011. V.D. 127 (H = 1). From isobutyric aldehyde and PCl_5 (Oeconomides, *C. R.* 92, 884). Aqueous NH_3 at 180° gives chloro-isobutylene (67°).

Di-chloro-isobutane $C_4H_8Cl_2$. (107°). From chloro-isobutylene $CH_2:CMe.CH_2Cl$ and conc. HCl (Chéchoukoff, *Bl.* [2] 43, 112).

Di-chloro-butane $C_4H_8Cl_2$. (128°) (P.); (125°) (Faraday). S.G. $\frac{22}{}$ 1·112. V.D. 4·43. Formed by union of Cl with the mixture of butylenes (*q. v.*) obtained by treating isobutyl alcohol (25 pts.) with H_2SO_4 (25 pts.), $CaSO_4$ (40 pts.), and K_2SO_4 (10 pts.) (Puchot, *A. Ch.* [5] 28, 508; *cf.* Faraday, *Tr.* 1825, 440; Kolbe, *A.* 69, 269; 64, 339).

Di-chloro-butane $C_4H_8Cl_2$. (106°). From *tert*-butyl chloride and Cl in daylight (D'Ottreppe de Bouvette, *Belg. Acad. Bull.* [3] 4, 359).

Tetra-chloro-butane $C_4H_6Cl_4$ *i.e.* $CH_3.CCl_2.CHCl.CH_2Cl$. (85°) at 10 mm. From tri-chloro-butyl alcohol by gradual addition of PCl_5 (Garzarolli-Thurnlackh, *A.* 213, 372). Oil.

Tetra-chloro-butane $CH_2Cl.CHCl.CHCl.CH_2Cl$. *Butinene tetra-chloride.* [73°]. From butinene and Cl. Also from erythrite and PCl_5 (Henninger, *Bl.* [2] 34, 195). Prisms.

Tetra-chloro-iso-butane $CCl_3.CMe_2Cl$. *Tri-chloro-tri-methyl-carbinyl chloride* or *chloro-isobutyro-tri-chloride.* (167°). Strong odour. Formed, together with hexa-chloro-di-*tert*-butyl oxide $(CCl_3.CMe_2)_2O$, by the action of PCl_5 upon acetone-chloroform (Willgerodt a. Dürr, *B.* 20, 539).

Hexa-chloro-butane $C_4H_4Cl_6$. (148°) at 50 mm. S.G. $\frac{12}{}$ 1·67. A liquid formed by the action of chlorine on isobutyl iodide (Prunier, *Bl.* [2] 24, 24).

Hexa-chloro-butane $C_4H_4Cl_6$. Formed by the action of chlorine on $C_4H_8Cl_2$ (from isobutyl alcohol) in sunlight (Puchot, *C. R.* 85, 757). Oil. Converted by KOH into $C_4H_2Cl_6$, C_4Cl_2, and C_4Cl_4.

Hexa-chloro-butane $C_4H_4Cl_6$. (c. 115°) *in vacuo.* From *tert*-butyl chloride and chlorine in sunlight (d'O. de B.).

Hepta-chloro-butane $C_4H_3Cl_7$. [86°]. (125°–135°) *in vacuo.* From *tert*-butyl chloride and Cl in sunlight (d'O. de B.).

Hepta-chloro-butane $C_4H_3Cl_7$. [42°]. (135°-145°) *in vacuo*. Formed at the same time as the preceding.

CHLORO-BUTANE TETRA-CARBOXYLIC ACID $CCl(CO_2H)_2.C(C_2H_5)(CO_2H)_2$. *Ethyl-chloro-acetylene-tetra-carboxylic acid.*

Tetra-ethyl-ether $A^{iv}Et_4$. S.G. $\frac{20}{15}$ 1·076. Formed by chlorination of butane-tetra-carboxylic ether. Oil (Bischoff a. Rach, *B.* 17, 2786).

CHLORO-BUTENYL ALCOHOL C_4H_7ClO. *Chloro-crotyl alcohol.* (158·3° i.V.) at 742·5 mm. S.G. $\frac{15}{15}$ 1·1312. V.D. 3·60 (for 3·68). From tri-chloro-butyl alcohol by zinc-dust and HCl (Garzarolli-Thurnlackh, *A.* 213, 375). Crystallises in a freezing mixture. Smells like allyl compounds. M. sol. water, but separated by K_2CO_3 or NaCl. Forms with Br in $CHCl_3$ chloro-di-bromo-butyl alcohol, which is very unstable. If it be oxidised by HNO_3 it forms chloro-di-bromo-butyric acid (not isolated), which is reduced by zinc-dust and HCl to chloro-crotonic acid [97°].

Acetate (168°–169°) at 741 mm. V.D. 5·23 (for 5·14). Colourless fruity liquid, heavier than water. V. sl. sol. water.

CHLORO-BUTINENE C_4H_5Cl. (65°). From di-chloro-butylene $CH_3.CH:CH.CHCl_2$ and alcoholic KOH (Kekulé, *A.* 162, 99).

Hexa-chloro-butinene C_4Cl_6. [39°]. (284°). From *s*-hexyl-iodide and ICl_3 at 100°–240° (Krafft, *B.* 10, 803). Thin prisms (from alcohol).

TRI-CHLORO-BUTYL ACETATE $C_4H_6Cl_3OAc$. (217·5°) at 733 mm. S.G. $\frac{8\cdot5}{8\cdot5}$ 1·344. From tri-chloro-butyl alcohol and AcCl at 110° (Garzarolli-Thurnlackh, *A.* 213, 373).

α-CHLORO-ISOBUTYL ALCOHOL C_4H_9ClO *i.e.* $(CH_3)_2CCl.CH_2OH$ *Butylene-glycol chlorhydrin* (137°). From isobutylene and HClO (Butlerow, *A.* 144, 25). Sl. sol. water. Reduced by sodium-amalgam to isobutyl alcohol. Oxidised by HNO_3 to chloro-isobutyric acid (Henry, *B.* 9, 1034).

Chloro-*sec*-butyl alcohol. *Ethyl ether* $CH_3.CH_2.CH(OEt).CH_2Cl$. (141°). S.G. $\frac{0}{}$ ·9735. From di-chloro-di-ethyl oxide and $ZnEt_2$ (Lieben, *A.* 123, 133).

Di-chloro-*tert*-butyl alcohol $C_4H_8Cl_2O$. (143·5° i.V.). S.G. $\frac{0}{}$ 1·0335. From $(CH_3)_2C:CHCl$ and HClO (Oeconomides, *C. R.* 92, 1235).

Tri-chloro-butyl alcohol $CH_3.CCl_2.CHCl.CH_2.OH$ [62°]. (120°) at 45 mm. From tri-chloro-butyric aldehyde (butyl chloral) and $ZnEt_2$, $ZnPr_2$, or $Zn(CH_2Pr)_2$, followed by water, thus: $C_3H_4Cl_3CHO + Zn(C_2H_5)_2 = C_3H_4Cl_3.CH_2OZnC_2H_5 + C_2H_4$ (Garzarolli-Thurnlackh, *A.* 213, 360; 223, 166). Also from urochloralic acid and HCl (Mering, *H.* 4, 93). Prisms (from ether). V. sol. alcohol or ether, sl. sol. hot water. Sol. warm conc. H_2SO_4, but decomposed by heating the solution.

Reactions.—1. PCl_5 has hardly any action.—2. Fuming HBr at 110° has no action.—3. PCl_5 gives tetra-chloro-butane.—4. Fuming HNO_3 gives tri-chloro-butyric acid.—5. *Zinc-dust* and HCl reduce it to chloro-butenyl alcohol (*q.v.*).

Tri-chloro-*tert*-butyl-alcohol *v.* ACETONE-CHLOROFORM.

CHLORO-ISO-BUTYL-ISO-AMYL-GLYOXALINE (?) $C_{12}H_{21}ClN_2$. *Chloro-oxalamyline.* (267°-270°). Prepared from di-isoamyl-oxamide in the same way as chloro-oxalethyline from di-ethyl-oxamide (Wallach a. Schulze, *B.* 13, 516; *A.* 214, 316).

Salts.—$(B'HCl)_2PtCl_4$.—B'HCl.

γ-CHLORO-*n*-BUTYL-BENZENE $C_{10}H_{13}Cl$ *i.e.* $C_6H_5.CHCl.C_3H_7$. From $C_6H_5.CH(OH).C_3H_7$ and HCl (Engler a. Bethge, *B.* 7, 1128). Liquid.

CHLORO-ISO-BUTYLENE $(CH_3)_2C:CHCl$. *Iso-butenyl chloride. Isocrotyl chloride.* (c. 65°). S.G. $\frac{12}{}$ ·979. V.D. 39·7. From isobutylidene chloride $(CH_3)_2CH.CHCl_2$ and alcoholic KOH or NH_3. Formed together with $(CH_3)_2CH.CHCl_2$, by treating isobutyric aldehyde with PCl_5 (Oeconomides, *C. R.* 92, 884, 1235; *Bl.* [2] 35, 498). Formed also by the action of chlorine on isobutylene, especially below 0° (Scheschukoff, *J. R.* 16, 493; *Bl.* [2] 41, 253; 43, 127). Converted by water at 90° into isobutyric aldehyde.

Chloro-isobutylene $CH_3.C(CH_2Cl):CH_2$. *Butenyl chloride.* (c. 73°). S.G. $\frac{0}{}$ ·955. Formed, together with the preceding, by chlorinating isobutylene, especially above 0° (S.). Heated with aqueous K_2CO_3 it forms isobutenyl alcohol (113°). HCl forms $C_4H_8Cl_2$ (107°), whence K_2CO_3 gives $C_4H_8(OH)_2$ (178°).

Di-chloro-*n*-butylene $CH_3.CH:CH.CHCl_2$. (126°). S.G. $\frac{20}{}$ 1·131. From crotonic aldehyde and PCl_5 (Kekulé, *A.* 162, 98). Alcoholic KOH gives C_4H_5Cl (65°) and $C_4H_6Cl.OEt$ (134°). Br gives $C_4H_6Cl_2Br_2$ whence aqueous K_2CO_3 gives $C_4H_6ClBr(OH)_2$ (c. 118°).

Tetra-chloro-butylene $C_4H_4Cl_4$. (200°). From tri-chloro-butyric aldehyde and PCl_5 (Judson, *B.* 3, 790).

Penta-chloro-butylene $C_4H_3Cl_5$. (187°) at 460 mm. From *tert*-butyl alcohol and chlorine (Lieben, *B.* 8, 1017).

TRI-CHLOR-BUTYLIDENE-IMIDE $CH_3.CHCl.CCl_2.CH:NH$. [164°–165°]. (P. a. K.); [170°] (S.). Prepared by the action of ammonium acetate on tri-chloro-butyric ortho-aldehyde (hydrate of butyrochloral) (Pinner a. Klein, *B.* 11, 1491). Also by heating tri-chloro-butyric aldehyde-ammonia with benzoic aldehyde (R. Schiff, *G.* 9, 438). Sol. alcohol, ether, hot water and hot benzene.

α-CHLORO-ISOBUTYL-MALONIC ACID $C_4H_9.CCl:(CO_2H)_2$. *Di-ethyl-ether* $A''Et_2$. (246°). S.G. $\frac{15}{}$ 1·091. Prepared by the action of chlorine on isobutyl-malonic ether. Liquid. On saponification with KOH it gives iso-butyl-oxy-malonic acid (Conrad a. Bischoff, *B.* 13, 600; *A.* 209, 237).

HEXA-CHLORO-DI-TERT-BUTYL OXIDE $C_8H_{12}Cl_6O$ *i.e.* $(CCl_3.CMe_2)_2O$. '*Acetone-chloroform ether.*' (156°). Formed, together with $CCl_3.CMe_2OH$, and its oily isomeride, by the action of PCl_5 upon acetone-chloroform (Willgerodt a. Dürr, *B.* 20, 539). Liquid. Volatile with steam. Very pungent.

α-CHLORO-*n*-BUTYRIC ACID $C_4H_7ClO_2$ *i.e.* $CH_3.CH_2.CHCl.CO_2H$. From its chloride and water. Thick liquid, v. sol. hot water.

Chloride $CH_3.CH_2.CHCl.COCl$. (c. 131°). S.G. $\frac{17}{}$ 1·257. Formed by chlorinating butyryl chloride in presence of iodine (Markownikoff, *A.* 153, 241; *cf.* *Z.* [2] 4, 621).

Ethyl ether EtA'. (c. 158°). S.G. $\frac{17\cdot5}{}$ 1·068 (M.).

β-Chloro-*n*-butyric acid $CH_3.CHCl.CH_2.CO_2H$.

Formation.—1. By saponification of allyl cyanide by HCl (Pinner, *B.* 12, 2056).—2. By oxidation of the corresponding aldehyde (Karetnikoff, *J. R.* 11, 252).—3. By treating the hydrochloride of β-chloro-butyric imido-ether $CH_3.CHCl.CH_2.C(NH)(OEt)$ with water (Pinner, *B.* 17, 2008).

Reactions.—Boiling baryta-water forms HCl and crotonic acid.

Ethyl ether EtA'. (c. 170°). S.G. ^{0} 1·072 (Ba.); $\frac{20}{4}$ 1·0517 (Br.). μ_β 1·430. R_∞ 59·1. Obtained by chlorinating butyric acid (Balbiano, *B.* 10, 1749; 11, 348; *G.* 10, 137). Probably the same compound is got by saturating an alcoholic solution of crotonic acid with HCl (Brühl, *A.* 203, 28). Converted by KOH into crotonic acid and β-oxy-butyric acid. Heated with alcoholic NH_3 it gives β-amido-butyramide.

γ-Chloro-butyric acid $CH_2Cl.CH_2.CH_2.CO_2H$. [10°]. S.G. $\frac{10}{}$ 1·250. From the nitrile by HCl (Henry, *C. R.* 101, 1158). Viscous liquid or thin laminæ, sl. sol. water. At 190° it splits up into HCl and the lactone of γ-oxy-butyric acid.

Methyl ether MeA'. (174°). S.G. $\frac{10}{10}$ 1·891. From the nitrile, MeOH, and HCl.

Ethyl ether EtA'. (184°). S.G. $\frac{10}{10}$ 1·122.

Chloride $CH_2Cl.CH_2.CH_2.COCl$. (174°). S.G. $\frac{10}{10}$ 1·268.

Amide $CH_2Cl.CH_2.CH_2.CONH_2$. [90°].

Nitrile $CH_2Cl.CH_2.CH_2.CN$. (196°). S.G. $\frac{10}{10}$ 1·162. From $CH_2Cl.CH_2.CH_2Br$ and KCy.

α-Chloro-isobutyric acid $(CH_3)_2CCl.CO_2H$. From $(CH_3)_2CCl.CH_2OH$ by oxidation with HNO_3 (Henry, *Bl.* [2] 26, 24). Formed also by chlorinating isobutyric acid (Balbiano, *B.* 11, 1693).

Ethyl ether EtA'. (149° cor.). S.G. ^{0} 1·062. Converted by alkalis into oxy-isobutyric, methacrylic, and 'di-butyllactic' ($C_8H_{14}O_5$) acids (Testa, *G.* 10, 377).

αβ-Di-chloro-butyric acid $CH_3.CHCl.CHCl.CO_2H$ [63°]. Formed by combining solid crotonic acid with chlorine, in CS_2 solution. Large glistening colourless prisms. By aqueous NaOH at the ordinary temperature it is converted into *allo*-α-chloro-crotonic acid [66°]. If the solution is heated during the reaction some ordinary α-chloro-crotonic acid is formed simultaneously. On heating the neutral alkaline salts in aqueous solution *allo*-α-chloro-propylene is formed (Wislicenus, *B.* 20, 1008; Michael a. Brown, *Am.* 9, 281; *J. pr.* [2] 36, 174; *cf.* Friedrich, *A.* 219, 371).

Salts.—AgA'.—BaA'$_2$: gummy.

Methyl ether MeA'. (84°) at 28 mm.; (177°). S.G. ^{0} 1·2809 (Zeisel, *M.* 7, 368).

Ethyl ether EtA'. (96°) at 35 mm. Converted by alcoholic KOH into α-chloro-crotonic acid [98°].

Chloride $CH_3.CHCl.CHCl.COCl$. (164°). From crotonic aldehyde and chlorine (Z.).

***Allo*-αβ-di-chloro-butyric acid** $CH_3.CHCl.CHCl.CO_2H$. Liquid. Formed, together with some solid αβ-di-chloro-butyric acid [63°], by combination of liquid iso-crotonic acid with Cl. By excess of cold aqueous NaOH it is converted into ordinary α-chloro-crotonic acid [99°]. On heating the neutral aqueous solution of the alkaline salts, ordinary α-chloro-propylene (30°) is formed (Wislicenus, *B.* 20, 1009).

A di-chloro-butyric acid is formed by chlorinating *n*-butyric acid in sunlight (Pelouze a. Gélis, *A. Ch.* [3] 10, 434; Naumann, *A.* 119, 120).

αα-Di-chloro-butyric acid. *Anilide.* $CH_3.CH_2.CCl_2.O.NHPh$. [200°]. From aniline ethyl-malonate and PCl_5 (Schramm, *B.* 21, 289). Distillation with aqueous Na_2CO_3 converts it into NPh:CH.O.CClEt.CO NHPh which yields phenyl-carbamine when boiled with conc. KOHAq.

o-Toluide $CH_3.CH_2.CCl_2.ONHC_7H_7$. Prepared in a similar way. Is converted by aqueous Na_2CO_3 into NC_7H_7:CH.O.CClEt.CO.NHC_7H_7. [107°].

Tri-chloro-butyric acid $CH_3.CHCl.CCl_2.CO_2H$. [60°] (K.); [58°] (G.). (237°). S. 4. Formed by oxidising tri-chloro-butyric aldehyde (Krämer a. Pinner, *B.* 3, 389; Judson, *B.* 3, 785; Kahlbaum, *B.* 12, 2337). From the alcohol and fuming HNO_3 (Garzarolli-Thurnlackh, *A.* 213, 374; 182, 185). The silver salt when boiled with water gives di-chloro-propylene (78°).—AgA'.—CaA'$_2$.—PbA'$_2$.

Ethyl ether EtA'. (212°).

Chloride $CH_3.CHCl.CCl_2.COCl$. (c. 164°).

Amide $CH_3.CHCl.CH_2.CONH_2$. [96°].

Tri-chloro-butyric acid $CH_2Cl.CH_2.CCl_2.CO_2H$. [75°]. S. 5. From the corresponding aldehyde and fuming HNO_3 (Natterer, *M.* 4, 539; 5, 251).

Tri-chloro-isobutyric acid $C_4H_5Cl_3O_2$. [50°]. Separates when chlorine is passed into an aqueous solution of sodium citraconate (Gottlieb, *J. pr.* [2] 12, 1). Prisms. Boiling alkalis convert it into di-chloro-methacrylic acid. Zinc-dust and HCl form chloro-methacrylic acid.

Salts.—NH$_4$A'.—BaA'$_2$.—PbA'$_2$.—Aniline salt NH$_2$PhHA'. [164°] (Daccomo, *J.* 1884, 1385).—[4:1]$C_6H_4Me.NH_3A'$. [154°] (D.).

Tetra-chloro-butyric acid $C_4H_4Cl_4O_2$. [140°]. From *n*-butyric acid and Cl in sunlight (Pelouze a. Gélis, *A. Ch.* [3] 10, 434).

β-CHLORO-*n*-BUTYRIC ALDEHYDE C_4H_7ClO *i.e.* $CH_3.CHCl.CH_2CHO$. [97°]. From crotonic aldehyde and gaseous HCl (Kekulé, *A.* 162, 100). Needles (from dilute alcohol); insol. water.

Tri-chloro-butyric aldehyde $CH_3.CHCl.CCl_2.CHO$.

Butyl-chloral. Mol. w. 175½. (165°). S.G. $\frac{20}{4}$ 1·3956. μ_β 1·482. R_∞ 57·99 (Brühl, *A.* 203, 20).

Formation.—1. By the action of chlorine on aldehyde (Pinner, *A.* 179, 21; *B.* 3, 383; 8, 1561). 2. From chloro-acetic ortho-aldehyde by heating with an equivalent quantity of aldehyde and a trace of HCl; the oily product (α-chloro-crotonic aldehyde) being subsequently chlorinated (Lieben a. Zeisel, *M.* 4, 531).

Properties.—Liquid; combines with water forming a crystalline hydrate, whence it is liberated by distillation in a current of HCl. Oxidation gives tri-chloro-butyric acid. PCl_5 gives $C_4H_4Cl_4$ (200°).

Reactions.—1 $ZnMe_2$ in ether followed, after a time, by water gives tri-chloro-amyl alcohol $(C_3H_4Cl_3)CHMeOH$.—2. $ZnEt_2$ (1 mol.) gives off ethylene, and the residue when treated with water forms tri-chloro-butyl alcohol (Garzarolli-Thurnlackh, *A.* 213, 370).—3. Tri-chloro-lactic acid at 130° gives $CCl_3.CH\left<\begin{matrix}O\\CO_2\end{matrix}\right>CH.C_3H_4Cl_3$ [107°] (Wallach, *A.* 193, 47).—4. Lactic acid gives $CH_3.CH\left<\begin{matrix}O\\CO_2\end{matrix}\right>CH.C_3H_4Cl_3$ (261°). — 5. Tri-chloro-oxy-valeric acid at 175° slowly forms $C_3Cl_3H_4CH\left<\begin{matrix}O\\CO_2\end{matrix}\right>CH.C_3Cl_3H_4$ [85°]. (300°–310°) (W.).—6. PH_4I forms $C_8H_{13}Cl_6PO_2$ [96°] (Girard, *A. Ch.* [6] 2, 52). Split up by conc. NaOHAq into HCl, H_3PO_3, $C_3H_4Cl_2$, formic acid and hydrogen.

Combinations. — 1. **With water:**— ***Tri-chloro-butyric ortho-aldehyde*** $CH_3.CHCl.CCl_2.CH(OH)_2$. Mol. w. 193½. [78°] (K. a. P.); [75°] (L. a. Z.). V.D. 3·33 (calc. 6·7) (Moitesier, *C. R.* 90, 1075). Trimetric laminæ; $a:b:c = ·65:1:1·2$. Dissociated by heat. *Reactions.*—(*a*) Converted by boiling Na_2CO_3Aq into di-chloro-propylene (77°) which on oxidation with CrO_3 yields acetic acid.—(*b*) Zn and HCl reduce it to chloro-crotonic and crotonic aldehydes (Sarnow, *A.* 164, 108).—(*c*) Iron and HOAc give butyric aldehyde, *n*-butyric alcohol, and butenyl alcohol (Lieben a. Zeisel, *M.* 1, 840).—(*d*) After being taken into the system it is excreted in urine as **tri-chloro-butyl-glycuronic acid** $C_{10}H_{15}Cl_3O_7$ (Mering, *H.* 6, 491; Külz, *J. Th.* 1882, 95). This acid crystallises in silky needles, is lævorotatory, and split up by boiling dilute acids into glycuronic acid and tri-chloro-butyl alcohol.—(*e*) Heated with dry NH_4OAc it forms $C_4H_5Cl_3NH$ [165°] (Pinner a. Klein, *B.* 11, 1491); [170°] (Schiff, *B.* 11, 2167).

2. **With hydrogen cyanide:**— ***Tri-chloro-oxy-valeronitrile*** $CH_3.CHCl.CCl_2.CH(OH).CN$. [102°]. (c. 230°). This is converted by alcoholic NH_3 into chloro-crotonamide; and by H_2SO_4 into tri-chloro-oxy-valeramide. Heated with urea it yields chloro-crotonyl-urea $CH_3CH:CCl.CO.NH.CO.NH_2$ as chief product (about 60 p.c.) and **butyro-chloral-biuret** $CH_3.CHCl.CCl_2.CH\left<\begin{matrix}NH.CO\\NH.CO\end{matrix}\right>NH$ as a by-product (about 6 p.c.) (Pinner a. Lifschütz, *B.* 20, 2347).

3. **With acetamide:**—$C_4H_5Cl_3(OH)(NHAc)$. [170°] (Pinner, *A.* 179, 40); [158°] (Schiff a. Tassinari, *B.* 10, 1785). Tables; v. sl. sol. water.

4. **With benzamide:**—$C_4H_5Cl_3(OH)(NHBz)$. [150°] (Pinner, *A.* 179, 40); [133°] (Schiff a. Tassinari, *B.* 10, 1785). Formed by melting tri-chloro-butyric aldehyde with benzamide.

5. **With carbamic ether:**— $C_4H_5Cl_3(OH)(NH.CO_2Et)$. [125°]. From tri-chloro-butyric aldehyde, carbamic ether, and HCl (Bischoff, *B.* 7, 632). Small prisms.

6. **With ammonia:**—[62°] (S. a. T.).

7. **With alcohol:**— $CH_3.CHCl.CCl_2.CH(OH)(OEt)$. Oil (P.).

8. **With acetyl chloride:**— $CH_3.CHCl.CH_2.CH(OAc)Cl$ (220°).

Tri-chloro-butyric aldehyde $CH_2Cl.CH_2.CCl_2.CHO$. [–78°]. From αγ-di-chloro-crotonic aldehyde $CH_2Cl.CH:CCl.CHO$ and HCl (Natterer, *M.* 4, 551; 5, 253). Forms no hydrate.

β-CHLORO-BUTYRIMIDO-ETHYL-ETHER $C_3H_6Cl.C(NH).OEt$. The hydrochloride is formed *by passing HCl into a mixture of allyl cyanide* (1 mol.) and ethyl alcohol (1 mol.). The hydrochloride (B′HCl) crystallises in large colourless prisms (Pinner, *B.* 17, 2007).

CHLORO-CAFFEÏNE *v.* Caffeïne.

CHLORO-CAMPHOR *v.* Camphor.

CHLORO-CAPROIC ACID *v.* Chloro-hexoic acid.

CHLORO-TRICARBALLYLIC ACID. *Methyl ether* $CH_2(CO_2Me).CCl(CO_2Me).CH_2(CO_2Me)$. From tri-methyl citrate and PCl_5 (Hunæus, *B.* 9, 1750). Oil; split up by heat into HCl and tri-methyl aconitate.

TRI-CHLORO-CARBAZOLE $C_{12}H_6Cl_3N$. [180°]. Prepared by passing chlorine into acetic acid containing carbazole in suspension until the mass appears bright green (Græbe, *A.* 202, 27). Needles; sol. benzene, ether, and alcohol. Its solution in conc. H_2SO_4 is bright green. Its **picric acid compound** [100°] forms red needles.

Hexa-chloro-carbazole $C_{12}H_3Cl_6N$. [225°]. Obtained by further chlorination of the above. Long needles; its solution in conc. H_2SO_4 is yellowish-green.

Octo-chloro-carbazole $C_{12}HCl_8N$. [275°]. Formed by chlorinating the above in presence of $SbCl_5$. Long needles, sl. sol. alcohol. Further chlorination in presence of $SbCl_5$ at 160° gives hexa-chloro-benzene.

CHLORO-CARBONIC ETHER *v.* Chloro-formic ether.

(β)-CHLORO-CARBOSTYRIL C_9H_6ClNO *i.e.*

$$C_6H_4\left<\begin{matrix}CH{:}CCl\\ \quad\ \ |\\ N:C(OH)\end{matrix}\right.$$

(*Py.* 2, 3)-*Chloro-oxy-quinoline.* [242°]. Formed by heating di-chloro-quinoline [104°] with dilute HCl to 120°. By PCl_5 it is converted back into the di-chloro-quinoline [104°] (Friedländer a. Weinberg, *B.* 15, 336, 2679).

Ethyl ether $C_9H_5ClN(OEt)$: liquid, volatile with steam.

Chloro-carbostyril C_9H_6NOCl. [246°]. Formed by boiling a dilute HCl solution of *o*-amido-phenyl-propiolic acid (Baeyer a. Bloem, *B.* 15, 2148). Sublimable. Silky needles. Sl. sol. hot, insol. cold, water. May be identical with the above.

Di-chloro-carbostyril $C_9H_5Cl_2NO$. [249°]. Formed by chlorination of carbostyril (Friedländer a. Weinberg, *B.* 15, 1425). Fine white needles. PCl_5 converts it into tri-chloro-quinoline [161°].

DODECA-CHLORO-CEROTIC ACID $C_{27}H_{42}Cl_{12}O_2$. From cerotic acid and chlorine (Brodie, *A.* 67, 190). Gummy mass. EtA′.

CHLORO-CETYL ALCOHOL $C_{16}H_{33}ClO$. (300°). From cetene $C_{16}H_{32}$ and cold dilute HClO (Carius, *A.* 126, 195). Liquid. KOH gives $C_{16}H_{32}O$ [30°] (300°).

DI-CHLORO-CHELIDAMIC ACID *v.* Chelidonic acid.

HEPTA-CHLORO-CHOLESTERIN *v.* Cholesterin.

CHLORO-CHROMIC ACID. Name sometimes given to CrO_2Cl_2, *v.* Chromium, *Oxychlorides of.*

CHLORO-CHRYSENE *v.* Chrysene.

α-CHLORO-CINNAMIC ACID

$C_6H_5.CH:CCl.CO_2H$. *α-Chloro-β-phenyl-acrylic acid.* [142°].

Formation.—1. By heating sodium chloro-acetate with acetic anhydride and benzoic aldehyde (Plöchl, *B.* 15, 1945).—2. By heating α-chloro-β-oxy-β-phenyl-propionic acid with NaOAc and Ac_2O (Forrer, *B.* 16, 854).—3. Together with a small quantity of the β isomeride by heating $C_6H_5.CHCl.CHCl.CO_2H$ with alcoholic KOH (Jutz, *B.* 15, 788).—4. By digesting benzoyl-acetic ether with PCl_5 and $POCl_3$ at 100° (Perkin, *C. J.* 47, 240). In this reaction the β acid might have been anticipated. Needles. Volatile with steam. V. sl. sol. water, v. sol. alcohol and ether, sl. sol. ligroïn.

β-Chloro-cinnamic acid $C_6H_5.CCl:CH.CO_2H$. ? *Allo-α-chloro-cinnamic acid.* [114°]. Formed as above (*Formation* 3) and separated from the α-acid by the smaller solubility of its potassium salt in alcohol. Trimetric crystals (Haushofer, *Z. K.* 8, 382, 389).

o-**Chloro-cinnamic acid** $[2:1]C_6H_4Cl.CH:CH.CO_2H$. [200°]. (G. a. H.); [196°] (S.). Formed by boiling *o*-diazo-cinnamic acid with strong HCl (Gabriel a. Herzberg, *B.* 16, 2036). Also by heating *o*-chloro-benzylidene-malonic acid to its melting-point (Stuart, *C. J.* 53, 141). Sol. alcohol, ether, and acetic acid, nearly insol. petroleum-ether and hot water.

m-**Chloro-cinnamic acid** $[3:1]C_6H_4Cl.C_2H_2.CO_2H$. [167°]. Formed by boiling *m*-diazo-cinnamic acid with strong HCl (G. a. H. *B.* 16, 2038). Needles. V. sol. hot water, hot alcohol and ether, sl. sol. benzene and petroleum-ether.

p-**Chloro-cinnamic acid** $[4:1]C_6H_4Cl.C_2H_2.CO_2H$. [242°]. Formed by boiling *p*-diazo-cinnamic acid with strong HCl (Gabriel a. Herzberg, *B.* 16, 2039). V. sol. alcohol, sl. sol. cold water, benzene, and ether.

Di-chloro-cinnamic acid $C_6H_3.Cl_2.CH:CHCO_2H$ [1:3:6]. Formed by the action of Ac_2O and NaOAc on (β)-dichloro-benzoic aldehyde (Seelig, *A.* 237, 168). Fine needles (from dilute alcohol).

(α)-**Tri-chloro-cinnamic acid** $C_6H_2Cl_3.CH:CH.CO_2H$ [1:3:4:6]. [201°]. Formed by acting on (α)-trichloro-benzoic aldehyde with acetic anhydride and sodium acetate (Seelig, *A.* 237, 151).

(β)-**Tri-chloro-cinnamic acid** $C_6H_2.Cl_3.CH:CH.CO_2H$ [1:2:3:6]. [185°].

Formed by the action of acetic anhydride and sodium acetate on (β)-tri-chloro-benzoic aldehyde (Seelig, *A.* 237, 151).

CHLORO-CITRACONIC ACID $C_5H_5ClO_4$. The salts of this acid are formed from the anhydride. The free acid, liberated by the addition of H_2SO_4 to the barium salt, splits up at once into water and anhydride. Zn and HCl reduce it to pyrotartaric acid.

Salts.—CaA″.—BaA″3½aq.—BaA″4aq.—PbA″.—AgHA″.—Ag_2A″.

Anhydride $C_5H_3ClO_3$. [99°]. (212°). Formed by distilling citra-di-chloro-pyrotartaric or chloro-citramalic acid (Gottlieb, *J. pr.* [2] 8, 73; Swarts, *J.* 1873, 582). Laminæ; may be sublimed. Sl. sol. water, v. sol. alcohol and ether.

CHLORO-CITRIC ACID $C_6H_7ClO_7$. From aconitic acid and HOCl (Pawolleck, *A.* 178, 155). Unstable syrup. Boiling with water or baryta-water gives oxy-citric acid.

CHLORO-CODEÏNE *v.* Codeïne.

CHLORO- COMPOUNDS. *See also* Bromo-Compounds. In organic compounds chlorine can displace hydrogen atom for atom, the resulting compound possessing as a rule considerable resemblance to the parent substance. This observation in the hands of Laurent and Dumas overthrew the electro-chemical theory of chemical affinity which had been established by Berzelius (*cf. K.* 1, 66). The hydrogen that is displaced by chlorine is usually that attached to carbon. Chlorination may be effected by a mixture of $KClO_3$ and HCl, by PCl_5, $SbCl_5$, or AcCl, but it is usually effected by the direct action of chlorine gas. The chlorination of aromatic hydrocarbons may be effected by heating the hydrocarbons with the theoretical amount of PCl_5 at 190°; in this case the PCl_5 splits up into PCl_3 and chlorine, the latter then attacking the side chains; the products are nearly pure (Colson a. Gautier, *Bl.* [2] 45, 6; *C. R.* 101, 1064). In the same way acetyl chloride heated for several weeks with PCl_5 in an open flask is converted into chlorinated acetyl chlorides (Michael, *Am.* 9, 215). Acetyl chloride itself may be used as a chlorinating agent; thus benzene-azo-benzene heated with AcCl at 170° for 4 hours is converted into *p*-chloro-benzene-azo-chloro-benzene and *p*-chloro-acetanilide (Becker, *B.* 20, 2006). When free chlorine is used the substitution is usually slow unless it is aided by daylight, by sunlight, by heat, or by carriers.

Sunlight enables chlorine to enter the side chains of aromatic hydrocarbons even at 0° (Schramm, *B.* 18, 1272), which it will otherwise only do at a high temperature; in the cold and in the dark it only enters the benzene nucleus. Chlorine enters the methyl group of acetophenone whether the action take place in daylight or in the dark; the chlorination is, however, much more rapid in daylight (Gautier, *C. R.* 104, 1714).

Carriers. Iodine greatly assists chlorination, probably forming ICl_3, which reacts more vigorously than chlorine alone (Hugo Müller, *C. J.* 15, 41). The chlorides of metals which form two chlorides also act as carriers; *e.g.* $SbCl_5$ (Hugo Müller; Beilstein a. Geitner, *A.* 139, 334; Ruoff, *B.* 9, 1466), $MoCl_5$ (Aronheim, *B.* 8, 1400; 9, 1788; Page, *A.* 225, 199), Fe_2Cl_6, Al_2Cl_6, TlCl, and the chlorides of Au, Sn, Bi, S, Te, Ga, Zr, Nb, In, Ta, and Ur. On the other hand the chlorides of Na, K, Li, Ag, Cu, Ca, Ba, Sr, Mg, Zn, Hg, B, P, As, Se, Y, Ce, and Di, are not carriers (Willgerodt, *J. pr.* [2] 34, 264; 35, 398). According to Page, however, the chlorides of Sn, S, and Bi are not carriers, as is also the case with the chlorides of Ti, Cr, W, Mn, Co, and Ni. It is, however, not possible to draw an absolute line of demarcation between carriers and non-carriers; the weaker carriers can only attack substances prone to chlorination. The effect of various chlorides is modified by circumstances, such as their solubility in the substance to be chlorinated, their stability in presence of water, and the temperature of the reaction. $MoCl_5$ acts as a carrier of chlorine to aromatic bodies only and not to fatty compounds. It may be supposed that these various carriers act by alternately giving up chlorine to the compound and taking it up again:

$$C_6H_6 + MoCl_5 = C_6H_5Cl + MoCl_3 + ClH$$
$$MoCl_3 + Cl_2 = MoCl_5.$$

This does not account for the fact that carriers promote entrance into the benzene nucleus, nor for the observation that no ferrous chloride is formed when benzene is heated with Fe_2Cl_6. An alternative supposition is that in the case of aromatic bodies a molecular compound is first formed, possibly aided by the somewhat unsaturated condition of the benzene ring, and that this molecular compound is subsequently decomposed by chlorine.

Displacement of one halogen by another. Iodo- compounds may be converted into chloro- compounds by digestion with $HgCl_2$; on the other hand, chloro- compounds may be changed to iodo- compounds by treatment with KI or, better, $CaI_2 3\frac{1}{2}H_2O$. Even acetyl chloride may be converted into acetyl iodide by heating with crystallised calcium iodide, without being affected by the water of crystallisation. In general, metals with low atomic weights prefer the lighter halogens. The following elements prefer chlorine to bromine or iodine, and bromine to iodine; viz., K, Mg, Ca, Sr, Ba, Al, Mn, Co.

On the other hand, Cu, Ag, Hg, Sn, Pb, As, and Sb prefer iodine to bromine or chlorine, and bromine to chlorine. P and Ti are indifferent. The metals Zn, Cd, Tl, Bi, Fe, and Ni are variable in their behaviour (Köhnlein, *A.* 225, 194).

Thus *n*-propyl iodide is not acted on by $MgCl_2$, $SrCl_2$, or $BaCl_2$; it is split up into gas and HI by $MnCl_2$ and $TiCl_4$; it is but slightly affected by $FeCl_2$, $CoCl_2$, and $NiCl_2$; but it is converted into propyl chloride by $ZnCl_2$, $CdCl_2$, $SnCl_4$, $SnCl_2$, $SbCl_3$, and TlCl.

n-Propyl chloride is converted into propyl iodide by CaI_2, SrI_2, MnI_2, and CoI_2; is but slightly affected by FeI_2 and NiI_2; and is not affected by SnI_2.

The substitution of chlorine by iodine may be effected by the use of KI in the case of chloro-lactic acid, chloro-acetone, di-chloro-acetone, epichlorhydrin, and dichlorhydrin; on the other hand, KI does not act on dichlorinated ethyl oxide, and decomposes chloral into chloroform and CO.

The substitution of Cl by I may be effected by Al_2I_6 in the case of CCl_4 and $CH_3.CHCl_2$; but Al_2I_6 does not act on C_6Cl_6 or on C_2Cl_4, while it splits up C_2Cl_6 into C_2Cl_4 and Cl_2.

KBr converts di-chloro-acetone into di-bromo-acetone. Al_2Br_6 converts CCl_4, C_2Cl_4, and C_2Cl_6 into CBr_4, C_2Br_4, and C_2Br_6 respectively.

The conversion of EtI into EtCl is not effected by $BaCl_2$, $CuCl_2$, or $PbCl_2$ at 72°, but is partially brought about by $BaCl_2$ at 140°, and is completely effected by $CuCl_2$ and $PbCl_2$ at 160°. The observation of Henry (*C. R.* 96, 1062) that silver nitrate converts ethylene chlorobromide $CH_2Cl.CH_2Br$ into chloro-ethyl nitrate $CH_2Cl.CH_2O.NO_2$ is in accordance with the statement made above, that silver prefers bromine to chlorine. Chlorine may be displaced by iodine by heating with conc. HIAq in sealed tubes, but the resulting iodo- compound is, especially in the case of aromatic compounds, liable to loss of iodine in exchange for hydrogen; thus chloro-benzenes are reduced to benzene by HI at 250° without any iodo-benzenes being formed (Berthelot, *Bl.* [2] 9, 30).

Chlorinated hydrocarbons.

Formation.—1. By chlorination of hydrocarbons. Chlorine enters the ω and α positions in fatty hydrocarbons; thus *n*-pentane gives

$$CH_3.CH_2.CH_2.CH_2.CH_2Cl$$

and $CH_3.CH_2.CH_2.CHCl.CH_3$. On further chlorination, the chlorine turns out hydrogen that is attached to the same atom of carbon as the chlorine atom already present. In the case of aromatic hydrocarbons chlorine enters the side chain only at a high temperature or in sunlight. In presence of iodine or $SbCl_5$ it enters the benzene nucleus even at boiling temperature (*v. supra*). The rules relating to substitution in the benzene nucleus are given in the article BENZENE. The displacing action of chlorine is not confined to hydrogen; thus it can convert nitro-benzene into C_6Cl_6 (Page, *A.* 225, 208).—2. Mono-chlorinated hydrocarbons or alkyl chlorides are formed by treating alcohols with HCl, PCl_5, PCl_3, or $POCl_3$. The action of HCl on alcohols is promoted by $ZnCl_2$ (Groves, *C. J.* 27, 636; *A.* 174, 372; Krüger, *J. pr.* [2] 14, 195), but in the case of the higher fatty alcohols the resulting chloride is sometimes mixed with an isomeride derived from the olefine formed by dehydration of the alcohol (Schorlemmer, *C. J.* 28, 308; *B.* 7, 1792). The polyhydric alcohols will not exchange all their hydroxyls for Cl by treatment with HCl but require the use of PCl_5.—3. From olefines and HCl; the chlorine attaching itself to the atom of carbon that is combined with the fewer hydrogen atoms. Di-chlorinated hydrocarbons are formed by the union of Cl with olefines, or of HCl with the hydrocarbons C_nH_{2n-2}. Although chlorine combines with olefines in the dark, its combination with benzene and acetylene requires light (Römer, *A.* 233, 172).—4. From aldehydes or ketones and PCl_5.—5. From aromatic amines by the diazo- reaction (*v.* DI-AZO-COMPOUNDS and AMINES). The conversion may also be effected by gradually adding HNO_2 to a hot solution of the amine in HCl (Losanitsch, *B.* 18, 39).

Reactions.—1. Boiling *water* very slowly decomposes chlorinated hydrocarbons; the chlorides of tertiary alkyls are the most readily affected (Niederist, *A.* 183, 388). Presence of $Pb(OH)_2$ or K_2CO_3 in the water promotes the conversion of chlorinated hydrocarbons into alcohols. If two chlorine atoms are attached to the same carbon atom, the product is an aldehyde or ketone; if three are attached to the same carbon atom, the product is an acid.—2. *Ammonia* converts the alkyl chlorides into amines. 3. *Alcoholic potash* removes HCl in two stages from di-chlorinated hydrocarbons, the Cl and H being detached from neighbouring carbon atoms, the hydrogen coming from the carbon atom to which the less hydrogen is attached.—4. Chlorine may be displaced by hydrogen by treatment with sodium-amalgam in presence of dilute alcohol; with zinc-dust and HOAc; or with conc. HIAq.—5. Dry *oxalic acid* displaces chlorine by oxygen in the compounds $RCHCl_2$ and $RCCl_3$ (Anschütz, *A.* 226, 18).

Chlorinated acids.

Formation.—1. By direct chlorination; chlorine taking the α position if possible, especially if the temperature be not above 100° (Erlenmeyer, *B.* 14, 1318).—2. From salts of oxy- acids and PCl_5, the resulting chlorinated alkoyl chloride being decomposed by water.—3. By addition of chlorine or of HCl to unsaturated acids; HCl uniting with acids of the form $RCH{:}CH.CO_2H$ gives rise chiefly to β-chloro- acids $RCHCl.CH_2.CO_2H$.

Reactions.—1. Boiling with *water* or alkalis usually converts α-chloro- acids into oxy- acids, β-chloro- acids into unsaturated acids, and γ-chloro- acids into lactones. The β-chloro- acids also split up into HCl, CO_2, and an olefine (Fittig, *A.* 195, 169; *cf.* Erlenmeyer, *B.* 14, 1318; 15, 49). KOEt converts α-chloro- acids into ethoxy- acids. αα-di-chloro- acids are but slightly affected by boiling water; αβ-di-chloro- acids give the chloro-oxy- acid, and also split off CO_2. Alcoholic KOH converts acids of the form $RCHCl.CHCl.CO_2H$ chiefly into $RCH{:}CCl.CO_2H$.

Acid chlorides.

Formation.—1. By the action of PCl_5, PCl_3, or $POCl_3$ on the acid or on a dry salt of the acid (Gerhardt, *A.* 87, 63; Béchamp, *C. R.* 40, 944; Kanonnikoff, *A.* 175, 378). Although PCl_5 does not convert tri-chloro-methane-sulphonic acid into its acid chloride, it acts upon methane sulphonic acid and chloro-methane sulphonic acid in the usual way.—2. By the action of HCl on a mixture of the acid and P_2O_5 (Friedel, *Z.* 1869, 489).

Reactions.—1. Quickly decomposed by *water* into HCl and the corresponding acid, and even more readily decomposed by *alcohols* with formation of ethers.—2. *Ammonia* forms amides; primary *amines* act similarly.—3. *Salts of organic acids* form anhydrides. Dry *oxalic acid* also converts them into anhydrides (Anschütz, *A.* 226, 13; *v.* ANHYDRIDES, ORGANIC).—4. *Zinc ethyl* unites with them forming compounds such as $R.C(OZnEt)EtCl$ which are converted by water into ketones $R.CO.Et$; further action of zinc ethyl forms $R.C(OZnEt)Et_2$ whence water forms tertiary alcohols $R.C(OH)Et_2$. Thus $CO_2Et.COCl$ becomes $CO_2Et.C(OH)Et_2$ (Henry, *B.* 5, 949).—5. *Aluminium chloride* forms with acetyl chloride diluted with CS_2 a white solid $C_{12}H_{14}O_6Al_2Cl_8$ decomposed by water into $CH_3.CO.CH_2.CO.CH_3$ with evolution of CO_2, and by alcohol into acetyl-aceto-acetic ether. Al_2Cl_6 acts similarly on chlorides of other normal fatty acids (Combes, *A. Ch.* [6] 12, 199).—6. *Chlorine* acts by substitution more vigorously upon acid chlorides than upon the acids themselves (Jazukowitzsch, *Z.* 1868, 234).—7. *Sodium amalgam* added to a mixture of an acid with its chloride reduces the latter to the corresponding alcohol (Linnemann, *A.* 161, 184; Baeyer, *B.* 2, 98).

Chloroamides and chloroimides $R'.NHCl$, $R'_1R'_2NCl$, $R''NCl$ where R', R'_1, and R'' are acid radicles, and R'_2 acid or alcoholic.

These bodies are formed by adding a conc. solution of chloride of lime to the solution of the amide or imide acidified with AcOH.

By treatment with alkalis, HCl, &c., their Cl atom is readily replaced by H (Bender, *B.* 19, 2272).

CHLORO-CONIINE *v.* CONIINE.

(α)-CHLORO-COUMARIN $C_9H_5ClO_2$. [123°]. From coumarin and PCl_5 at 200°. Also from coumarin dichloride and alcoholic KOH (Perkin, *C. J.* 24, 43). Flat needles, m. sol. alcohol, sl. sol. hot water. Converted by alcoholic KOH into coumarilic acid.

(β)-Chloro-coumarin $C_9H_5ClO_2$. [162°]. From Ac_2O and sodium chloro-*o*-oxy-benzoic aldehyde $C_6H_3Cl(ONa)CHO$ (Bäsecke, *A.* 154, 85). Crystals, sl. sol. cold alcohol, v. e. sol. benzene. Boiling KOHAq converts it into chloro-coumaric acid.

Tetra-chloro-coumarin $C_9H_2Cl_4O_2$. [145°]. Formed by passing chlorine into coumarin dissolved in CCl_4 containing iodine (P.). Small needles (from alcohol).

CHLORO-*p*-CRESOL $C_6H_3(CH_3)Cl(OH)$ [1:3:4] (196°). S.G. $\frac{25}{25}$ 1·2103. Formed by the action of dry chlorine on sodium-*p*-cresol (Schall a. Dralle, *B.* 17, 2528). Liquid.

Methyl ether $C_6H_3MeCl(OMe)$. (214°). S.G. $\frac{25}{25}$ 1·1493. Liquid.

Chloro-cresol $C_6H_3(CH_3)Cl(OH)$ or $C_6H_4(CH_2Cl)(OH)$. [56°]. (c. 240°). Formed by chlorination of boiling crude cresol (Biedermann, *R.* 9, 325). Needles; v. sol. alcohol, ether, and benzene.

Chloro-cresol. *Ethyl ether* $C_6H_3MeCl(OEt)$., (c. 215°). S.G. $\frac{19.5}{}$ 1·127. From (α)-chloro-nitro-toluene by reduction, diazotisation, and treatment of the diazo- sulphate with boiling alcohol (Wroblewsky, *A.* 168, 209).

Chloro-cresol. *Ethyl ether* $C_6H_3MeCl(OEt)$. (c. 215°). S.G. $\frac{18}{}$ 1·131. From (β)-chloro-nitro-toluene in the same way as the preceding (W.).

Di-chloro-*p*-cresol $C_6H_2(CH_3)Cl_2(OH)$ [39° uncor.]. Formed by passing chlorine into boiling *p*-cresol (Claus a. Riemann, *B.* 16, 1598). Long prismatic needles. Sol. alcohol and ether, sl. sol. hot water. By CrO_3 in acetic acid it is oxidised to di-chloro-*p*-oxy-benzoic acid [156° uncor.].—$A'NH_4$: long colourless needles [125°], sublimable.

Di-chloro-*m*-cresol $C_6H_2(CH_3)Cl_2(OH)$; probably [1:4:6:3]. [46° uncor.]. Formed by chlorinating *m*-cresol (Claus a. Schweitzer, *B.* 19, 930). Colourless needles. Volatile with steam. V. e. sol. alcohol, ether, &c., sol. hot water, nearly insol. cold. It is oxidised by $K_2Cr_2O_7$ and dilute H_2SO_4 to di-chloro-toluquinone [103°].

Di-chloro-*o*-cresol $C_6H_2(CH_3)Cl_2(OH)$ [1:5:3or4:2] [54° uncor.]. Formed by chlorination of *o*-cresol (C. a. R., *B.* 16, 1600). Large colourless needles. V. sol. alcohol, ether, benzene, chloroform and CS_2, sol. hot water, sl. sol. cold water. By CrO_3 and glacial acetic acid it is oxidised to a mixture of di- and tri-chloro-toluquinone. By $K_2Cr_2O_7$ and dilute H_2SO_4 it is oxidised to mono-chloro-toluquinone [90°] (Claus a. Schweitzer, *B.* 19, 927).

***Exo*-Di-chloro-*o*-cresol** $C_6H_4(CHCl_2)(OH)$ [1:2]. [82°]. From salicylic aldehyde (1 mol.) and PCl_5 (1 mol.) (Henry, *B.* 2, 135). Prisms (from ether); v. sl. sol. cold alcohol.

Phosphoryl derivative $PO(O.C_6H_4.CHCl_2)_3$. [78°]. From salicylic aldehyde and PCl_5 (Stuart, *C. J.* 53, 402). Needles (from alcohol). Not affected by boiling dilute NaOH Aq.

Methyl ether C_6H_4(CHC[illegible]. (231°). From $C_6H_4(OMe)CHO$ [1:2] and PCl_5 (Stuart, *C. J.* 53, 401). Oil. Decomposed in moist air.

Tri-chloro-cresol $C_6H(CH_3)Cl_3(OH)$. [96°]. (270°). One of the products of distillation of crude penta-chloro-thymol (Lallemand, *J.* 1856, 620). Crystals; insol. water, sol. alcohol and alkalis.

Tetra-chloro-cresol $C_6(CH_3)Cl_4(OH)$. [150°]. Obtained by distilling pure penta-chloro-thymol (L.). Needles.

α-CHLORO-CROTONIC ACID
$CH_3.CH:CCl.CO_2H$. [97·5°]. (206°) (Kahlbaum, *B.* 12, 2335); (212°) (Sarnow). S. 1·97 at 12° (K.); 2·12 at 19° (Michael a. Brown, *Am.* 9, 283).

Formation.—1. From tri-chloro-butyric aldehyde by oxidation and treatment of the resulting tri-chloro-butyric acid with zinc and HCl (Krämer a. Pinner, *A.* 158, 37) or with zinc-dust and water (Sarnow, *A.* 164, 93; *B.* 4, 731; 5, 467).—2. By boiling tri-chloro-butyric aldehyde (29 g.) with K_4FeCy_6 (42 g.) and water (500 g.) (Wallach, *B.* 10, 1530).—3. From solid crotonic acid by addition of chlorine followed by heating the product $CH_3.CHCl.CHCl.CO_2H$ (Friedrich, *A.* 219, 373).—4. From chloro-butenyl alcohol (*q. v.*) by oxidation.—5. By the action of cold aqueous NaOH upon the liquid *allo*-αβ-di-chloro-butyric acid (the addition product of isocrotonic acid and Cl) (Wislicenus, *B.* 20, 1009).

Properties.—Small flat needles; may be sublimed. Volatile with steam. Not attacked by alkalis below 220°, at which temperature acetic and oxalic acids are formed, together with CO_2 and a syrupy acid (F.). Reduced by sodium-amalgam to crotonic acid.

Salts.—A'K: pearly plates or tables (from 80 p.c. alcohol); nearly insol. absolute alcohol.—NH_4A'; laminæ.—CaA'_2.—BaA'_2: laminæ.—PbA'_2 aq.—CuA'_2: needles.—CuA'(OH): amorphous.—AgA': needles.

Methyl ether MeA'. (161°). S.G. ^{0} 1·0933 μ_D 1·4589 (Kahlbaum, *B.* 12, 344).

Ethyl ether EtA'. (177° uncor.). S.G. ^{15} 1·129. From tri-chloro-butyric aldehyde and alcoholic KCN (Wallach a. Böhringer, *A.* 173, 301, *cf.* Claus, *A.* 191, 63). Turns brown in light.

Reactions.—1. Treated with KCN (2 mol.) and boiling alcohol it forms a product whence boiling KOH produces tri-carballylic acid (Claus, *A.* 191, 64) and crotaconic acid, $C_4H_4(CO_2H)_2$, isomeric with itaconic acid. The tricarballylic acid is formed through addition of HCN to the crotaconic acid.—2. With KCN (2 mol.) and dilute alcohol in the cold it forms potassic cyano-crotonate (*q.v.*) only.

Chloride.—$CH_3.CH:CCl.COCl$. (142°). (S.).

Amide $CH_3.CH:CCl.CO.NH_2$ [112°] (P. a. K.); [107°] (S.). (c. 235°) (S.). From the cyanhydrin of tri-chloro-butyric aldehyde and alcoholic NH_3 or dry ammonium carbonate (Pinner a. Klein, *B.* 11, 1488). Also from the chloride and NH_3 (S.). Laminæ; may be sublimed.

Nitrile $CH_3.CH:CCl.CN$. (136°). From the amide and P_2O_5 (S.).

Allo-α-**chloro-crotonic acid** $CH_3.CH:CCl.CO_2H$. [67°]. S. 6·53 at 19°. Formed by the action of an excess of aqueous NaOH upon αβ-di-chloro-butyric acid [63°] at the ordinary temperature (Wislicenus, *B.* 20, 1009; Michael a. Brown, *Am.* 9, 283). Slender needles (from water). More soluble in water than any of the other chloro-crotonic acids; sl. sol. cold ligroïn.—A'K: concentric needles; v. sol. absolute alcohol (difference from the α-acid, whose K-salt is nearly insoluble).—BaA'_2 3½ aq: crystals, sl. sol. alcohol.—PbA'_2 aq: prisms, sl. sol. water.—AgA': amorphous.

β-Chloro-crotonic acid $CH_3.CCl:CH.CO_2H$. [94·5°]. (c. 209°). S. 1·9 at 19° (Michael a. Brown, *Am.* 9, 283); 2·25 at 12° (K.); 2·8 at 19° (G.).

Formation.—1. The chloride of this acid is formed together with that of *allo*-β-chloro-crotonic acid by the action of excess of PCl_5 on aceto-acetic ether. The mixed chlorides are saponified by water and the product distilled, whereupon β-chloro crotonic acid passes over first (Geuther, *Z.* 1871, 237).—2. From tetrolic acid and fuming HCl (Friedrich, *A.* 219, 370).

Properties.—Slender monoclinic needles; $a:b:c = 1·2859:1:·6105$; $\beta = 73° 9'$; volatile with steam; may be sublimed at 100°. At 160° it slowly changes into *allo*-β-chloro-crotonic acid.

Reactions.—1. *Sodium amalgam* gives crotonic acid.—2. Boiling *aqueous potash* (7 p.c.) gives tetrolic acid (K.).—Stronger potash (18 p.c.) gives chiefly acetone.—3. *Sodium ethylate* gives the same ethoxy-crotonic acid as is got from *allo*-β-chloro-crotonic acid.

Salts.—NaA' ½aq: thin laminæ, v. e. sol. water.—BaA'_2: trimetric octahedra. S. 45 at 18°.—CuA'_2 aq.

Ethyl ether EtA'. (184° cor.). S. G. $^{16\cdot5}$ 1·111 (G.).

Allo-**β-chloro-crotonic acid**
$CH_3.CCl:CH.CO_2H$. [59·5°]. (195° cor.). S. 1·12 at 7°. Formed from aceto-acetic ether as above described (Geuther a. Fröhlich, *Z.* 1869, 270). Formed also by heating the preceding acid for 20 hours at 160° (Friedrich, *A.* 219, 363).

Properties.—Slender needles or prisms; volatile with steam; sublimes even at 20°. Not affected by boiling aqueous KOH.

Reactions.—1. Alcoholic KOH converts it into the ethyl derivative of *allo*-β-oxy-crotonic acid.—2. Conc. KOHAq forms acetone and CO_2, a small quantity of tetrolic acid $C_4H_4O_2$ [75°–77°] being also formed (Friedrich, *A.* 219, 341). Dilute KOH behaves similarly, but the tetrolic acid is the chief product.

Salts.—NaA' ½aq: satiny crystals, v. sol. water.—KA' aq.—TlA' ½aq.—$NH_4HA'_2$ aq.—CaA'_2 3aq.—BaA'_2 2aq: four-sided prisms.—MgA'_2 5aq.—ZnA'_2 2½aq.—PbA'_2 4aq.—MnA'_2 2aq.—CoA'_2 6aq.—NiA'_2 6aq.—CuA'_2 1½aq.—AgA'.

Methyl ether MeA'. (142° cor.). S.G. ^{15} 1·143.

Ethyl ether EtA'. (161° cor.). S.G. ^{15} 1·113. Boiling alcoholic KCN followed by KOH converts it into tri-carballylic acid (Claus a. Lischke, *B.* 14, 1089).

Isomeride of chloro-crotonic acid *v.* CHLORO-METHACRYLIC ACID.

αβ-Di-chloro-crotonic acid
$CH_3.CCl:CCl.CO_2H$. From ααβ-tri-chloro-butyric acid (1 mol.) and KOH (2 mols.) (Garzarolli, *B.* 9, 1209).

α-CHLORO-CROTONIC ALDEHYDE
$CH_3.CH:CCl.CHO$. (148°). Formed, together with tri-chloro-butyric aldehyde, by chlorinating aldehyde containing alcohol (Pinner, *A.* 179, 31). Formed also by heating the hydrate of chloro-

acetic aldehyde with aldehyde and a drop of fuming HCl at 100° (Lieben a. Zeisel, *M.* 4, 531). Liquid. Combines with chlorine forming tri-chloro-butyric aldehyde. Br gives chloro-di-bromo- and chloro-tri-bromo- butyric aldehydes (Pinner, *B.* 8, 1323).

αγ-Di-chloro-butyric aldehyde $CH_2Cl.CH:CCl.CHO$. (86°) at 18 mm. Gradually separates as an oil when the hydrate of chloro-acetic aldehyde is heated with a drop of H_2SO_4 at 100° (Natterer, *M.* 4, 539; 5, 567). Oil; solidifies when cooled with solid CO_2. Forms a crystalline compound with $NaHSO_3$. Reduces warm ammoniacal $AgNO_3$. Reduced by iron filings and acetic acid to *n*-butyl and butenyl alcohols. Oxidised by HNO_3 to oxalic and chloro-acetic acids. Br forms αγ-di-chloro-αβ-di-bromo-butyric aldehyde. HCl gives tri-chloro-butyric aldehyde. $ZnEt_2$ followed by dilute H_2SO_4 gives a di-chloro-hexenyl alcohol $C_6H_{10}Cl_2O$ (c. 117°) at 20 mm.

CHLORO-CROTONYL-UREA $CH_3.CH:CCl.CO.NH.CO.NH_2$. [224°]. The chief product of the reaction of the cyanhydrin of tri-chloro-butyric aldehyde with urea; the yield is about 60 p.c. Rhombic tables. Sol. alcohol. sl. sol. water. On heating it evolves HCl and is converted into di-oxy-ethylidene-metapyrazole

(Pinner a. Lifschütz, *B.* 20, 2347).

CHLORO-CROTYL *v.* CHLORO-BUTENYL.

CHLORO-ψ-CUMENE $C_6H_2(CH_3)_3Cl$ [1:3:4:6]. [71°]. White plates. Formed by the action of cuprous chloride upon diazo-pseudo-cumene (Haller, *B.* 18, 93) or by warming the piperidide of diazo-pseudo-cumene with conc. HClAq (Wallach a. Heusler, *A.* 243, 232).

ω-Chloro *n*-cumene $C_9H_{11}Cl$ *i.e.* $C_6H_5.CH_2.CH_2.CH_2Cl$. *Chloro-propyl-benzene.* (219°). From $C_6H_5.CH_2.CH_2.CH_2OH$ and HCl (Errera, *G.* 16, 310). Oil. Not affected by fused $ZnCl_2$ nor by AgOAc. Alcoholic KOH gives $C_6H_5.C_3H_6.OEt$ (220°).

α-Chloro-*n*-cumene $C_6H_5.CH_2.CHCl.CH_3$. (c. 206°). From $C_6H_5.CH_2.CH(OH).CH_3$ and HCl (E.). Formed also by chlorination of *n*-propyl-benzene (Errera, *G.* 14, 506). Partially decomposed by distillation into HCl and allyl-benzene. Alcoholic KOH also forms allyl-benzene, as does $ZnCl_2$ likewise.

β-Chloro-*n*-cumene $C_6H_5.CHCl.CH_2.CH_3$. (c. 203°). From the corresponding phenyl-propyl alcohol and HCl (E.). Partially resolved by distillation, even *in vacuo*, into HCl and allyl-benzene. AgOAc forms $C_6H_5.CH(OAc).CH_2.CH_3$ (227°).

CHLORO-CUMINIC ACID $C_{10}H_{11}ClO_2$ *i.e.* $C_3H_7.C_6H_3Cl.CO_2H$ [4:3:1]. [123°]. Formed by oxidation by HNO_3 of the chloro-cymene from thymol and PCl_5 (Gerichten, *B.* 11, 365; Fileti a. Crosa, *G.* 16, 288). Long needles (from dilute alcohol). Reduced to cuminic acid by sodium-amalgam.—BaA'_2 3aq: pearly plates.

CHLORO-CUMOQUINOLINE *v.* CHLORO-ISO-PROPYL-QUINOLINE.

CHLORO-CYANAMIDE *v.* AMMELINE.

CHLORO-CYANO-BENZENE *v.* *Nitrile of* CHLORO-BENZOIC ACID.

CHLORO-DI-CYANO-NITRO-METHANE $CClCy_2(NO_2)$. Formed by warming chloropicrin with alcoholic KCy (Basset, *C. J.* 19, 352). Silver nitrate solution gives an orange pp. of $(AgNO_3)_4 3CClCy_2(NO_2)$.

CHLORO-CYMENE $C_{10}H_{13}Cl$ *i.e.* $C_6H_3MePrCl$ [1:4:2]. (210°). S.G. ^{14} 1·014. From carvacrol and PCl_5 (Kekulé a. Fleischer, *B.* 6, 1090). Formed also by chlorination of cymene (from camphor) in presence of iodine (v. Gerichten, *B.* 10, 1249). Oxidised by dilute HNO_3 to chloro-toluic acid [196°].

Chloro-cymene $C_6H_3MePrCl$ [1:4:3]. (213°). From thymol (4 mols.) and PCl_5 (1 mol.); the yield being 85 p.c. (Carstanjen, *J. pr.* [2] 3, 64; v. Gerichten, *B.* 10, 1250; 11, 365; Fileti a. Crosa, *G.* 16, 287). Not affected by sodium amalgam (F. a. C.). Oxidation gives chloro-cuminic [117°], chloro-toluic [149°], and chloro-terephthalic, acids.

ω-Chloro-cymene $C_6H_4Pr(CH_2Cl)$ [1:4]. *Cumyl chloride.* (c. 227°). Formed by passing chlorine into boiling cymene (Errera, *G.* 14, 277). Decomposed by long boiling with formation of $C_{20}H_{24}$. Alcoholic KOH gives $C_{10}H_{13}OEt$. Sodium amalgam reduces it to cymene. Boiling aqueous $Pb(NO_3)_2$ gives cuminic aldehyde.

***Exo*-chloro-cymene** $C_6H_4(C_3H_6Cl)Me$ [1:4]. Two compounds of this nature are formed, together with the preceding body, on passing chlorine into boiling cymene (derived from camphor). One of them is not attacked by alcoholic KOH, while the other is converted into allyl-toluene $C_6H_4(C_3H_5)Me$ (Errera, *G.* 14, 283).

ω-Chloro-*p*-isocymene $C_6H_4Pr(CH_2Cl)$ [1:4]. *Cumyl chloride.* (c. 230°). Formed, together with cumyl carbamate, by passing cyanogen chloride into cuminyl alcohol $C_6H_4Pr.CH_2OH$ (Spica, *G.* 5, 394). Formed also by the action of HCl on cuminyl alcohol (Paterno a. Spica, *G.* 9, 397; *B.* 12, 2366).

ωω-Di-chloro-cymene $C_6H_4(C_3H_7).(CHCl_2)$. *Cumylidene chloride.* (c. 258°). From cuminic aldehyde and PCl_5 (Cahours, *A.* 70, 44; *Suppl.* 2, 311; Sieveking, *A.* 106, 258). Reconverted by alcoholic KOH or by heating with water at 150° into cuminic aldehyde.

Tetra-chloro-*m*-isocymene C_6Cl_4PrMe [1:3]. [159°]. Formed by passing chlorine into a cold saturated solution of tri-chloro-isocymene sulphonic acid at 40° (Kelbe, *B.* 16, 617). Needles (from alcohol); may be sublimed. Not oxidised by HNO_3 or chromic mixture.

TRI-CHLORO-*m*-ISOCYMENE SULPHONIC ACID $C_6Cl_3PrMe(SO_3H)$. From *m*-isocymene sulphonic acid by passing Cl into its aqueous solution at 40° (Kelbe, *B.* 16, 618).—NaA': laminæ.

CHLORO-DECANE *v.* DECYL CHLORIDE.

CHLORO-DECYLENE $C_{10}H_{19}Cl$. (206° cor.). From Cl and boiling decanaphthene (Markownikoff a. Ogloblin, *J. R.* 15, 333). Alcoholic KOH gives a mixture of decinenes (155°-165°).

TETRA-CHLORO-DURENE $C_6H_2(CH_2Cl)_4$ [1:2:4:5]. [144°]. S.G. 1·479. Formed by heating durene with excess of PCl_5 at 190° for 5 hours (Colson a. Gautier, *C. R.* 102, 1075; *Bl.* [2] 46, 198).

DI-CHLORO-EOSIN *v.* DI-CHLORO-TETRA-BROMO-FLUORESCEIN.

CHLORO-ETHANE *v.* ETHYL CHLORIDE.

Di-chloro-ethane *v.* ETHYLENE CHLORIDE and ETHYLIDENE CHLORIDE.

Tri-chloro-ethane $CH_2Cl.CHCl_2$. *Chloro-ethylene chloride.* (114°) (Schiff, *A.* 220, 97); (115°) (Perkin, *C. J.* 45, 531). V.D. 4·66 (for 4·60). S.G. $\frac{9\cdot4}{4}$ 1·4577; $\frac{15}{15}$ 1·4553; $\frac{25}{25}$ 1·4430. M.M. 6·796 at 16·7°. C.E. (from 9° to 113°) ·00121. H.F.p. 83980 (*Th.*). H.F.v. 82820. S.V. 102·77.

Formation.—1. From chloro-ethylene (vinyl chloride) and $SbCl_5$ (Regnault, *A. Ch.* [2] 69, 151; 81, 355).—2. From ethyl chloride and Cl (Krämer, *B.* 3, 261).—3. By chlorinating ethylidene chloride in presence of Al_2Cl_6 (Tavildaroff, *B.* 13, 2403).—4. From $CHCl_2.CH_2OH$ and PCl_5 (de Lacre, *C. R.* 104, 1186).

Reactions.—1. Aqueous or alcoholic *ammonia* gives a theoretical yield of $C_2H_2Cl_2$ (37°) (Engel, *C. R.* 104, 1621); alcoholic KOH forms the same body.—2. *Sodium* forms C_2H_4, $C_2H_2Cl_2$, C_2H_2, and hydrogen (Brünner a. Brandenburg, *B.* 10, 1496; 11, 61).

Tri-chloro-ethane $CH_3.CCl_3$. (76°) (Perkin); (74·5°) (Geuther). V.D. 4·53. S.G. $\frac{15}{15}$ 1·3247; $\frac{25}{25}$ 1·3114. M.M. 6·740 at 17·6° (Perkin); ^{0} 1·347 (Pierre, *A.* 80, 127). Formed by chlorinating ethyl chloride (Regnault, *A.* 33, 317; Geuther, *J.* 1870, 435). Converted by NaOEt at 100° into CH_2:CCl(OEt), acetic acid, and ortho-acetic ether $CH_3.C(OEt)_3$. Differs from its isomeride in forming, when cooled, with aqueous H_2S, a crystalline compound $C_2H_3Cl_3 2H_2S$ 23aq (Forcrand, *A. Ch.* [5] 28, 25).

***u*-Tetra-chloro-ethane** $CH_2Cl.CCl_3$. (135°) (Regnault); 139° (Pierre, *A.* 80, 130); (130·5° i. V.) (Staedel, *B.* 15, 2563). S.G. ^{0} 1·6116 (P.); ^{12} 1·576. Formed by chlorinating ethylene chloride (Laurent, *A.* 22, 292) or $CHCl.CHCl_2$ (R.). With NaOEt it gives CHCl:CCl(OEt) and $CH_2(OEt).CO_2Na$. H_2S gives $C_2H_2Cl_4 2H_2S$ 23aq.

***s*-Tetra-chloro-ethane** $CHCl_2.CHCl_2$. *Acetylene tetrachloride.* (147° cor.). S.G. ^{0} 1·614 (P. a. P.); $\frac{0}{0}$ 1·5897 (Kanonnikoff).

Formation.—1. By passing acetylene into $SbCl_5$, which slowly absorbs it and deposits $C_2H_2SbCl_5$, the mixture of this body with $SbCl_5$ is then distilled (Berthelot a. Jungfleisch, *C. R.* 79, 542).—2. By passing acetylene into PCl_5; explosion often occurring (Sabanejeff, *A.* 216, 262).—3. By heating ethylene chloride with the calculated quantity of PCl_5 for ten hours at 190° (Colson a. Gautier, *C. R.* 102, 1075).—4. From di-chloro-acetic aldehyde and PCl_5 (Paternò a. Pisati, *G.* 1, 461; *J.* 1871, 508).

Properties.—Not affected by boiling water. Slowly decomposed at 360° giving HCl and hexa-chloro-benzene.

Penta-chloro-ethane $CHCl_2.CCl_3$. (158·9°) (Thorpe). S.G. $\frac{0}{4}$ 1·70893. C.E. (0°–10°) ·000949; (0°–100°) ·0009944. S.V. 138·2.

Formation.—1. From chlorine and EtCl (Regnault, *A.* 33, 321).—2. By chlorinating ethylene chloride (Pierre, *A.* 80, 130).

Preparation.—PCl_5 (190 g.) is gradually added to chloral (113 g.), boiled with inverted condenser and distilled. The portion distilling below 170° is washed with water, dried with $CaCl_2$, and rectified. The yield is small (Paternò, *C. R.* 68, 450; Thorpe, *C. J.* 37, 192).

Properties.—Liquid, solidifies below −18°. Converted by alcoholic KOH into KCl and C_2Cl_4. PCl_5 at 250° gives C_2Cl_6.

Hexa-chloro-ethane $CCl_3.CCl_3$. [179°] (Geuther a. Brockhoff, *J. pr.* [2] 7, 108); [185° cor.] (Hahn, *B.* 11, 1735). (185° cor.) (H.). S.G. 2·0 (Schröder, *B.* 13, 1070). V.D. 8·16 (calc. 8·21).

Formation.—1. From C_2Cl_4 and Cl in daylight or by heating (Faraday, *Tr.* 1826, 47; Liebig, *A.* 1, 219).—2. The ultimate product of the chlorination of ethyl chloride (Laurent, *A. Ch.* [2] 84, 328) or ethylene chloride (Faraday), and hence formed in the chlorination of most ethyl compounds in sunlight (Regnault, *A. Ch.* [2] 69, 166; 81, 371; Ebelmen a. Bouquet, *A. Ch.* [3] 17, 66; Malaguti, *A. Ch.* [3] 16, 6, 14; Geuther a. Hofacker, *A.* 108, 51).—3. By passing CCl_4 through a red-hot tube (Kolbe, *A.* 54, 147) or over finely divided copper at 120° (Radziszewski, *B.* 17, 834) or silver at 180° (Goldschmidt, *B.* 14, 928).—4. From AcCl and PCl_5 at 180° (Hubner a. Müller, *Z.* 1870, 328).—5. Ultimate product of the action of PCl_5 on succinic acid.—6. By heating propane, propyl chloride, or isobutyl chloride and ICl_3 at 200° (Krafft a. Merz, *B.* 8, 1298).—7. From propionic acid and ICl_3 (Krafft, *B.* 9, 1085).—8. By chlorination of boiling butyric acid in sunshine (Naumann, *A.* 119, 120).—9. Together with C_6Cl_6 and CCl_4 by heating chrysene with PCl_5 (Ruoff, *B.* 10, 1234).

Properties.—Tables (from alcohol-ether); smells like camphor. Trimorphous, crystallising in the cubic, trimetric, and triclinic systems (Lehmann, *J.* 1882, 369; *Z. K.* 6, 580). Insol. water, sol. alcohol and ether. When its vapour is led through a red-hot tube C_2Cl_4 is formed.

Reactions.—1. Alcoholic *potash* at 100° converts it into oxalic acid (Berthelot, *A.* 109, 118). Solid potash at 200° does the same (Geuther, *A.* 111, 174).—2. Boiling with NaOEt under pressure gives C_2Cl_4, CCl_2:CCl(OEt), $CHCl_2.C(OEt)_3$, and $CH_2(OEt).CO_2Na$ (Geuther a. Brockhoff). Zinc and dilute H_2SO_4 do the same.—3. Finely divided *silver* at 280° also gives C_2Cl_4.—4. SO_3 at 150° forms $CCl_3.COCl$ and $COCl_2$ (Prudhomme, *A.* 156, 342; Armstrong, *Pr.* 18, 502).—5. Al_2I_6 forms C_2Cl_4, Al_2Cl_6, and iodine (Gustavson, *B.* 9, 1607).

CHLORO-ETHANE TRI-CARBOXYLIC ACID.

Ethyl ether $(CO_2Et)_2.CCl.CH_2(CO_2Et)$ (205°–215°) at 160 mm. From ethane tri-carboxylic ether and chlorine (Bischoff, *A.* 214, 46).

Reactions.—1. Boiling aqueous HCl forms fumaric acid.—2. KOH and dilute alcohol form malic acid.—3. KOH and 97 p.c. alcohol appear to form $(CO_2Et)_2.C(OEt).CH_2.CO_2Et$.

α-CHLORO-ETHANE SULPHONIC ACID $CH_3.CHCl.SO_3H$. Its sodium salt A′Na is formed by heating ethylidene chloride with solution of Na_2SO_3 at 140°. This salt forms plates, sol. alcohol (Bunte, *A.* 170, 317).

β-Chloro-ethane sulphonic acid $CH_2Cl.CH_2.SO_3H$.

Formation.—1. By the action of fuming HNO_3 on $CH_2Cl.CH_2.SCy$ (James, *J. pr.* [2] 20, 353).—2. By boiling its chloride with water (Dittrich, *J. pr.* [2] 18, 67; Kolbe, *A.* 122, 33).—3. From $(CH_2Cl.CH_2)_2S_2$ and HNO_3 (Spring a. Lecrenier, *Bl.* [2] 48, 629).

Properties.—Very deliquescent needles. Not decomposed by boiling water. Heated with *ammonia* in sealed tubes at 100° forms taurine, $CH_2(NH_2)CH_2SO_3H$.

Salts.—(R. Hübner, *A.* 223, 213; James, *J. pr.* [2] 26, 382; *C. J.* 43, 41).—NH_4A'.—NaA'aq. KA': needles, insol. alcohol.—BaA'_2 aq (H.).—BaA'_2 2aq; needles (J.).—PbA'_2 2aq.—CuA'_2 3aq (H.).—CuA'_2 4aq: triclinic tablets (J.).—ZnA'_2 4aq (H.).—ZnA'_2 6aq: plates (J.).—MgA'_2 4aq.—SrA'_2 2aq: needles.—MnA'_2 4aq.—FeA'_2 4aq.—$NMeH_3A'$: plates (from alcohol).

Chloride.—$CH_2Cl.CH_2SO_2Cl$ (200°-205°). From potassic isethionate and PCl_5 (Kolbe, *A.* 122, 38). Also from $SO_2Cl.CH_2.CH_2.SO_2Cl$ and PCl_5 (Königs, *B.* 7, 1163). It is one of the products of the action of SO_3 on ethyl chloride (Purgold, *B.* 6, 502). Oil, smelling like mustard. Does not give an amide with ammonia, or an ether when heated with alcohol. PCl_5 at 200° gives ethylene chloride.

Di-chloro-ethane sulphonic acid $C_2H_3Cl_2(SO_3H)$. From ethane sulphonic acid and ICl_3 (Spring a. Winssinger, *B.* 15, 446). Converted by baryta into chloro-isethionic acid $C_2H_3Cl(OH)(SO_3H)$. Ammonia at 100° gives chlorinated taurine.

CHLORO-ETHENYL-TRICARBOXYLIC ACID *v.* CHLORO-ETHANE-TRICARBOXYLIC ACID.

CHLORO-ETHER *v.* CHLORO-ETHYL OXIDE.

CHLORO-ETHULMIC ACID $C_6H_9ClO_2$. A brown amorphous body formed by adding sodium to chloroform containing alcohol (Hardy, *A. Ch.* [3] 65, 340).

CHLORO-ETHYL-ACETAMIDE *v.* CHLORO-ETHYLAMINE.

ω-CHLORO-ETHYL ACETATE $CH_3.CHCl.OAc$ *v.* ALDEHYDE.

α-Chloro-ethyl acetate $CH_2Cl.CH_2.OAc$ *v.* CHLORO-ETHYL ALCOHOL.

Other Chloro-ethyl acetates *v.* Acetyl derivatives of the corresponding CHLORO-ETHYL ALCOHOLS.

CHLORO-ETHYL-ACETO-ACETIC ETHER $C_8H_{13}ClO_3$ *i.e.* $CH_2Cl.CO.CHEt.CO_2Et$ (192·5° cor.). S.G. ^{15} 1·052. A product of action of PCl_5 on ethyl-aceto-acetic ether (Isbert, *A.* 234, 187; *cf.* Conrad, *A.* 186, 241). Oil, smelling of peppermint. Sol. alcohol or ether. With dilute HCl at 180° it gives mono-chlorinated methyl propyl ketone. With NaOEt (1 mol.) in alcohol, it gives rise to ethoxy-ethyl-aceto-acetic ether $CH_2(OEt).CO.CHEt.CO_2Et$ (210° cor.). S.G. ^{22} ·957. Alcoholic KOH at 120° converts it into $EtO.CH_2.CO.CH_2Et$.

Di-chloro-ethyl-aceto-acetic ether $C_8H_{12}Cl_2O_3$. (220°-225°). S.G. ^{15} 1·183. Formed at the same time as the preceding.

Chloro-di-ethyl-aceto-acetic ether $CH_2Cl.CO.CEt_2.CO_2Et$. S.G. ^{15} 1·063. PCl_5 has no action on di-ethyl-aceto-acetic ether, even at 100°, but at a higher temperature HCl, EtCl, ethyl-chloro-crotonic (chloro-hexenoic) ether, di-ethyl-chloro-aceto-acetic ether, and di-ethyl-di-chloro-aceto-acetic ethers are formed. The product is freed from PCl_5 by distillation, is then poured into water and distilled with steam (James, *C. J.* 49, 50; *A.* 231, 235). Di-ethyl-chloro-aceto-acetic ether is a liquid, which is converted by treatment with sodium methylate MeONa into $CH_2(OMe).CO.CEt_2.CO_2Et$ and $CH_2(OMe).CO.CHMeEt$ (181°). S.G. ^{22} ·855.

Di-chloro-di-ethyl-aceto-acetic ether $CHCl_2.CO.CEt_2.CO_2Et$. S.G. ^{15} 1·155. One of the products of the action of PCl_5 on di-ethyl-aceto-acetic ether. Oil, with pleasant smell, Miscible with alcohol and with ether. Converted by NaOMe into $CH(OMe)_2.CO.CEt_2.CO_2Et$ (c. 195°) and $CH(OMe)_2.CO.CHEt_2$ (134°). S.G. ^{15} ·886 (James, *C. J.* 49, 57).

ω-CHLORO-ETHYL ALCOHOL $CH_3.CHCl.OH$. *Ethylidene chlorhydrin.* (25°) at 40mm. An unstable body formed by combination of aldehyde with HCl in the cold. It changes spontaneously into 'ethylidene oxy-chloride' or di-chloro-di-ethyl oxide (Hanriot, *A. Ch.* [5] 25, 219), *v.* ALDEHYDE, vol. i. p. 104.

Acetyl derivative $CH_3.CHCl.OAc.$ (121·5°, cor.). Formed by combination of aldehyde with acetyl chloride; *v.* ALDEHYDE, vol. i. p. 105, where other alkoyl derivatives are described.

Methyl derivative $CH_3.CHCl.OMe.$ (c. 74°). S.G. ^{17} ·996. Formed by passing HCl into a well-cooled mixture of aldehyde (1 vol.) and methyl alcohol (1½ vols.) (Rübencamp, *A.* 225, 269).

Ethyl derivative $CH_3.CHCl.OEt$ *v.* CHLORO-DI-ETHYL OXIDE.

Chloro-ethyl alcohol C_2H_5ClO *i.e.* $CH_2Cl.CH_2OH$. *Glycol chlorhydrin.* Mol. w. 80½ (128°-131°). S.G. ^{0} 1·2233.

Formation.—1. By repeatedly saturating glycol with HCl and distilling the product (Wurtz, *A.* 110, 125; *cf.* Schorlemmer, *C. J.* 39, 143). Besides the pure product (128°) a fraction boiling at 106° is obtained; this fraction may be represented as $(C_2H_5ClO)_2HCl$ 8aq, and has S.G. ^{0} 1·1926; by means of KOH (1 mol.) it may be decomposed with liberation of the pure chlorhydrin (Bouchardat, *C. R.* 100, 452).—2. By heating glycol with S_2Cl_2 at 100° and extracting the product with moist ether (Carius, *A.* 124, 257); the yield is over 50 p.c. of the theoretical.—3. From ethylene and ClOH (Carius, *A.* 126, 197; *cf.* Butlerow, *A.* 144, 40).—4. From ethylene oxide and HCl; the union is attended with disengagement of heat: $(C_2H_4O,HCl) = 36{,}000$ (Berthelot, *C. R.* 93, 185).

Properties.—Liquid, miscible with water. A mixture of glycol chlorhydrin (1 mol.) with water (4 mols.) solidifies at −17°.

Reactions.—1. *Oxidised* by chromic mixture to chloro-acetic acid (Kriwaxin, *Z.* 1871, 265).—2. Reduced by *sodium amalgam* and water to alcohol (Lourenço, *A.* 120, 92).—3. Converted by *potash* into ethylene oxide.—4. With $COCl_2$ in the cold, reacts thus: $CH_2Cl.CH_2OH + Cl_2CO = HCl + CH_2Cl.CH_2.O.COCl$, forming the chloro-ethylic ether of chloro-formic acid.—5. Heated with K_2SO_3 and water at 180° it forms isethionic acid $CH_2OH.CH_2SO_3H$.—6. *Ammonia* forms oxyethyl-amine $CH_2OH.CH_2NH_2$ together with $CH_2OH.CH_2.O.CH_2.CH_2NH_2$ (Wurtz, *A.* 114, 51; 121, 226).—7. *Trimethylamine* in aqueous solution forms neurine (Wurtz, *A. Suppl.* 6, 116, 197).—8. *Dimethylamine* gives di-methyl-oxy-ethyl-amine $CH_2OH.CH_2.NMe_2$ (Ladenburg, *B.* 14, 2408), and $CH_2OH.CH_2.O.CH_2.CH_2NMe_2$ (Morley, *C. J.* 37, 234).

Nitroxyl derivative $CH_2Cl.CH_2.O.NO_2$. *Chloro-ethyl nitrate.* (150°). S.G. ^{21} 1·378. From $CH_2Cl.CH_2OH$, nitric acid, and H_2SO_4, or from $CH_2Cl.CH_2Br$ and alcoholic $AgNO_3$ (*A. Ch.* [4] 27, 257; Henry, *C. R.* 96, 1062). Oil.

Acetyl derivative $CH_2Cl.CH_2OAc$. *Glycol chloracetin.* (145°). S.G. ^{0} 1·1783. *Formation.*—1. From glycol, HOAc, and gaseous HCl at 100°

(Simpson, *A.* 112, 147).—2. From $CH_2OH.CH_2OAc$ and HCl (Simpson, *A.* 113, 116).—3. From glycol and AcCl in the cold (Lourenço, *A. Ch.* [3] 67, 260; 114, 126).—4. From chloro-ethyl alcohol $CH_2Cl.CH_2OH$ and AcCl (Henry, *B.* 7, 70; Delacre, *Bl.* [2] 48, 707), or Ac_2O at 110° (Ladenburg a. Demole, *B.* 6, 1024). *Properties.*—Liquid; converted by aqueous potash into ethylene oxide.

Chloro-acetyl derivative $CH_2Cl.CH_2.O.CO.CH_2Cl$. (198°). From chloro-ethyl alcohol and chloro-acetyl chloride (Delacre, *Bl.* [2] 48, 708), or from ethylene and Cl_2O (Mulder a. Bremer, *B.* 11, 1958).

Di-chloro-acetyl derivative $CH_2Cl.CH_2.O.CO.CHCl_2$. (211°). S.G. ^{15} 1·200 (D.).

Tri-chloro-acetyl derivative $CH_2Cl.CH_2O.CO.CCl_3$. (217°). S.G. ^{15} 1·251 (D.).

Butyryl derivative $CH_2Cl.CH_2O.CO.Pr$. (190°). S.G. ^{0} 1·0854. From glycol, butyric acid, and gaseous HCl (Simpson, *A.* 113, 119).

Benzoyl derivative $CH_2Cl.CH_2.OBz$. (260°–270°). From glycol, benzoic acid, and HCl at 100° (S.).

ωa-Di-chloro-ethyl-alcohol $CH_2Cl.CHCl.OH$. *Acetyl derivative* $CH_2Cl.CHCl.OAc$. (c. 168°). From acetyl-chloride and the hydrate of chloro-acetic aldehyde (Natterer, *M.* 3, 453). Oil. An isomeride (147°) is formed by treating $CCl_3.CHCl.OAc$ with Zn and HOAc (Curie a. Milliet, *B.* 9, 1611).

Di-chloro-ethyl alcohol $CHCl_2.CH_2.OH$. (146° i.V.). S.G. ^{15} 1·145. V.D. 3·93 (calc. 3·97) (Delacre, *C. R.* 104, 1184). From di-chloro-acetic aldehyde and $ZnEt_2$, the product being decomposed by water. Liquid, sl. sol. water, sol. alcohol and ether. Reduces ammoniacal $AgNO_3$. Does not dissolve $CaCl_2$. Fuming HNO_3 gives di-chloro-acetic acid. Converted by PCl_5 into $CHCl_2.CH_2Cl$ (115°), and by PBr_3 into $CHCl_2.CH_2Br$ (138°).

Nitroxyl derivative $CHCl_2.CH_2.NO_3$. *Di-chloro-ethyl nitrate.* (156° i.V.). V.D. 5·56 (calc. 5·53) (De Lacre, *C. R.* 104, 1186). From $CHCl_2.CH_2OH$ by HNO_3 and H_2SO_4.

Acetyl derivative $CHCl_2.CH_2.OAc$. *Di-chloro-ethyl acetate.* (167° i.V.). V.D. 5·74 (calc. 5·42). S.G. ^{15} 1·104 (Delacre, *C. R.* 104, 1186).

Chloro-acetyl derivative $Cl_2CH.CH_2O_2C.CH_2Cl$. (215° cor.). S.G. ^{15} 1·216. Prepared by acting with mono-chloro-acetyl chloride on di-chloro-ethyl alcohol on the water-bath until no more hydric chloride is evolved (Delacre, *Bl.* [2] 48, 708).

Di-chloro-acetyl derivative $Cl_2CH.CH_2O_2C.CHCl_2$. (223°). S.G. ^{15} 1·25. Formed by heating di-chloro-ethyl alcohol and di-chloro-acetyl-chloride together on the water-bath (Delacre).

Tri-chloro-acetyl derivative $Cl_2CH.CH_2O_2C.CCl_3$. (230°). Formed by the action of tri-chloro-acetyl chloride on di-chloro-ethyl alcohol (Delacre).

Tri-chloro-ethyl alcohol $CCl_3.CH_2OH$. [18°]. (151°). S.G. ^{22} 1·550.

The zinc salt $(CCl_3.CH_2.O)_2Zn$ is formed by the action of $ZnEt_2$ on chloral; it is decomposed by water into $Zn(OH)_2$ and tri-α-chloro-ethyl alcohol (Garzarolli-Thurnlackh, *A.* 210, 63; Delacre, *Bl.* [2] 48, 785). It is also formed, together with glycuronic acid $C_6H_{10}O_7$, by treating urochloralic acid with dilute HCl (Külz, *Z. B.* 20, 161). Hygroscopic trimetric tables; sl. sol. water, v. sol. alcohol and ether. HNO_3 forms tri-chloro-acetic acid. Reduces hot Fehling's solution.

Acetyl derivative $Cl_3C.CH_2OAc$. (170°). S.G. ^{15} 1·189. Formed by digesting at a gentle heat acetyl chloride and trichloro-ethyl alcohol.

Chloro-acetyl derivative $Cl_3C.CH_2O_2C.CH_2Cl$. (220° cor.). S.G. ^{15} 1·25. From chloro-acetyl-chloride and tri-chloro-ethyl alcohol (Delacre, *Bl.* [2] 48, 710).

Di-chloro-acetyl derivative $Cl_3C.CH_2O_2C.CHCl_2$. (231°) at 767 mm. S.G. ^{15} 1·267. From di-chloro-acetyl chloride and tri-chloro-ethyl alcohol.

Tri-chloro-acetyl derivative $Cl_3C.CH_2O_2C.CCl_3$. [26°]. (236°). From tri-chloro-acetyl chloride and tri-chloro-ethyl alcohol.

ωaa-Tri-chloro-ethyl alcohol. *Acetyl derivative* $CHCl_2.CHCl.OAc$. (185°). From AcCl and di-chloro-acetic aldehyde (Delacre, *Bl.* [2] 48, 714).

DI-CHLORO-ETHYLAMIDO-ACETIC ETHER $C_6H_{11}Cl_2NO_2$ *i.e.* $NHEt.CCl_2.CO_2Et$. [above 50°]. From $NHEt.CO.CO_2Et$ and PCl_5 (Wallach, *A.* 184, 76). Needles or prisms. Water regenerates $NHEt.CO.CO_2Et$. Ammonia forms ethyl-oxamide.

***p*-CHLORO-TETRA-ETHYL-*p*-DI-AMIDO-TRI-PHENYL-CARBINOL** $C_6H_4Cl.C(OH):(C_6H_4.NEt_2)_2$. [121°]. Large glistening colourless tables. Formed by oxidation of its leuco-base, the condensation-product of diethylaniline and *p*-chlorobenzaldehyde. Its zinc double chloride is a bluish-green dyestuff (Kaeswurm, *B.* 19, 745).

TRI-CHLORO-*p*-ETHYL-AMIDO-PHENYL-ETHYL ALCOHOL $CCl_3.CH(OH).C_6H_4.NHEt$. [98°]. From chloral hydrate and ethyl-aniline. Crystals (from alcohol).—B'HCl.

Nitrosamine $CCl_3.CH(OH).C_6H_4.NEt.NO$ [138°]. Crystals (Boessneck, *B.* 21, 783).

Tri-chloro-di-ethyl-amido-phenyl ethyl alcohol $CCl_3.CH(OH).C_6H_4.NEt_2$. Yellow oil. Formed by adding 10 grms. of $ZnCl_2$ to a cold mixture of 60 grms. of diethylaniline and 20 grms. of chloral hydrate, and allowing to stand for 2 days at 40°. It is decomposed by alkalis into chloroform and *p*-di-ethyl-amido-benzaldehyde. —B'HCl: crystalline solid (Boessneck, *B.* 19, 367).

***p*-CHLORO-TETRA-ETHYL-*p*-DI-AMIDO-TRI-PHENYL-METHANE** $C_6H_4Cl.CH(C_6H_4.NEt_2)_2$. [110°]. Obtained by heating together di-ethyl-aniline, *p*-chloro-benzaldehyde, and $ZnCl_2$ (Kaeswurm, *B.* 19, 744). Small colourless needles. Sol. benzene, alcohol, and ether, insol. water. On oxidation it gives a bluish-green dyestuff.

CHLORO-ETHYL-AMINE *v. Ethyl-chloro-amine*, described under ETHYL-AMINE.

β-Chloro-ethyl-amine $Cl.CH_2.CH_2.NH_2$. From vinylamine and conc. HClAq. Formed also by heating oxyethylphthalimide with conc. HCl to 200° (Gabriel, *B.* 21, 573, 1049).—**Salts.**—B'HCl. V. e. sol. alcohol, ether, and water.—**Picrate.**—$B'C_6H_3N_3O_7$ ½aq. Yellow needles. [148° anhydrous]. $B'_2H_2PtCl_6$. Orange plates. V. sol. water, sl. sol. alcohol.

CHLORO-ETHYL-ANILINE $C_8H_{10}ClN$ *i.e.* $_6H_5.NH.CH_2.CH_2Cl$. Formed by the action of ming HCl at 170° on the compound $C_9H_9NO_2$ erived from phenyl-carbamic acid (*q. v.*).—HCl. [158°] (Nemirowsky, *J. pr.* [2] 31, 175).

p-**Chloro-ethyl-aniline** [4:1] $C_6H_4Cl.NHEt$. rom *p*-chloro-aniline and EtBr. Liquid (Hofmann, *A.* 74, 143).

p-**Chloro-di-ethyl-aniline** [4:1] $C_6H_4Cl.NEt_2$. rom the preceding and HBr (H.). Liquid.—$'_2H_2PtCl_6$.

Eso-**CHLORO-ETHYL-BENZENES** $_6H_4Cl.(C_2H_5)$. The three eso-chloro-ethyl-benzenes are obtained simultaneously by the action f C_2H_4 upon C_6H_5Cl (500 g.), in presence of $_2Cl_6$ (100 gr.). The mixture is an oily liquid .180°). S.G. $^{\underline{0}}$ 1·068. V.D. 4·77. Very volaile, and of agreeable odour. Sol. ligroïn (1 vol.), S_2, $CHCl_3$, and ether. Sol. C_6H_6 (2 vols.) and lcohol (3 vols.). The proportion of the three somerides is roughly $o : m : p = 7 : 10 : 3$. On xidation it gives a mixture of the three chloroenzoic acids. Heated with sulphuric acid it ives sulphonic acids (Istrati, *A. Ch.* [6] 6, 402; *Bl.* [2] 42, 114).

ω-**Chloro-ethyl-benzene** $CH_2Cl.CH_2.C_6H_5$ (?). . 202°). Formed by chlorinating boiling ethylenzene (Fittig a. Kiesow, *A.* 156, 246; *cf.* chramm, *M.* 8, 105). Split up by boiling into Cl and styrene. Converted by alcoholic KCy nto the nitrile of *β*-phenyl-propionic acid (?).

α-**Chloro-ethyl-benzene** $CH_3.CHCl.C_6H_5$. 194°). Formed by the action of chlorine on thyl-benzene in sunlight, and also on boiling thyl-benzene (Schramm, *M.* 8, 101). Formed lso by passing HCl into cold *ω*-phenyl-ethyl lcohol $C_6H_5.CH(OH).CH_3$ (Engler a. Bethge, *B.* , 1127). With benzene and Al_2Cl_6 it gives *s*-dihenyl-ethane (Anschütz, *A.* 235, 329).

Chloro-di-ethyl-benzenes $C_6H_3Cl(C_2H_5)_2$. A nixture of chloro-di-ethyl-benzenes is formed y treating C_6H_5Cl with C_2H_4 in presence of l_2Cl_6. It is a mobile liquid, with agreeable dour. (c. 218°). S.G. $^{\underline{0}}$ 1·036. V.D. 5·65. Sol. igroïn (in all proportions), CS_2, ether, and HCl_3. Sol. benzene (3 vols.), alcohol (7 vols.). n oxidation, it gives rise to two chloro-phthalic cids, and chloro-ethylphenyl methyl ketone $C_2H_5).C_6H_3.Cl.CO.CH_3$ (Istrati).

Chloro-tri-ethyl-benzenes $C_6H_2Cl(C_2H_5)_3$. A nixture of these substances is obtained by coninuing the passage of ethylene into chloroenzene in presence of Al_2Cl_6. Mobile liquid. 248°). V.D. 6·87. Sol. (in all proportions) ther, petroleum ether, CS_2, and $CHCl_3$. Sol. benzene ($3\frac{1}{2}$ vols.), and alcohol (30 vols.). On oxidation with permanganate it gives a tri-carboxylic acid, having an insol. Ba salt (Istrati, *A. Ch.* [6] 6, 426).

Chloro-tetra-ethyl-benzenes $C_6HCl(C_2H_5)_4$. A mixture of isomerides of this composition is formed by the further action of C_2H_4 upon C_6H_5Cl in presence of Al_2Cl_6. Liquid. S.G. $^{\underline{0}}$ 1·022. (c. 271). V.D. 7·17. V. sol. ether, ligroïn, CS_2, and $CHCl_3$. Sol. benzene (4 vols.) and 90 p.c. alcohol (26 vols.) (Istrati).

Chloro-penta-ethyl-benzene $C_6Cl(C_2H_5)_5$. Formed by the prolonged action of C_2H_4 upon C_6H_5Cl in presence of Al_2Cl_6. The yield is not good. Mobile liquid. S.G. $^{\underline{0}}$ 1·065. (c. 292°). V.D. 8·43. V. sol. ether, ligroïn, CS_2, and $CHCl_3$. Sol. benzene ($5\frac{1}{2}$ vols.) and 90 p.c. alcohol (32 vols.) (Istrati, *A. Ch.* [6] 6, 428).

Di-chloro-ethyl-benzene $C_6H_3Cl_2(C_2H_5)$ [1:4:2]. S.G. $^{\underline{0}}$ 1·239. (213°). V.D. 6·24. Formed by the action of C_2H_4 upon $C_6H_4Cl_2$ [1:4] in presence of Al_2Cl_6, at 125°–150° (Istrati, *A. Ch.* [6] 6, 476). Liquid. Sol. benzene (3 vols.) and 90 p.c. alcohol (9 vols.). Yields a di-chloro-benzoic acid on oxidation.

ωω-**Di-chloro-ethyl-benzene** $C_6H_5.CH_2.CCl_2H$. *Phenyl-di-chloro-ethane.* Formed by the action of PCl_5 on phenyl-acetic aldehyde (Forrer, *B.* 17, 982). Heavy colourless liquid. Volatile with steam. By boiling with water it is converted into *ω*-chloro-styrene.

αα-**Di-chloro-di-ethyl-benzene** $C_6H_5.CCl_2.CH_3$. *Acetophenone chloride.* From acetophenone and PCl_5 in the cold (Friedel, *Bl.* 1, 7; Ladenburg, *A.* 217, 105). Readily splits off HCl.

ωα-**Di-chloro-di-ethyl-benzene** $C_6H_5.CHCl.CH_2Cl$. *Styrene dichloride.* From styrene and chlorine (Blyth a. Hofmann, *A.* 53, 309). Decomposed on distillation. Alcoholic KOH gives $C_6H_5CH:CHCl$.

Di-chloro-di-ethyl-benzene $C_6H_2Cl_2(C_2H_5)_2$. A mixture of di-chloro-di-ethyl-benzenes is obtained by treating *p*-di-chlor-benzene with C_2H_4 in presence of Al_2Cl_6. Liquid. S.G. $^{\underline{0}}$ 1·179. (c. 247°). V.D. 7·17. Sol. benzene (4 vols.) and alcohol (16 vols.) (Istrati, *A. Ch.* [6] 6, 482).

Di-chlor-tri-ethyl-benzene $C_6HCl_2(C_2H_5)_3$ [1:4:3:5:6]. S.G. $^{\underline{0}}$ 1·131. (c. 273°). V.D. 8·77 (calc. 7·99). Formed by the action of C_2H_4 upon *p*-di-chlor-benzene in presence of Al_2Cl_6 (Istrati). Liquid. Sol. benzene (5 vols.), alcohol (80 vols.). HNO_3 gives $C_6(NO_2)Cl_2(C_2H_5)_3$. [20°]. (312°). H_2SO_4 gives $C_6(SO_3H).Cl_2.(C_2H_5)_3$.

Di-chloro-tetra-ethyl-benzene $C_6Cl_2(C_2H_5)_4$. S.G. $^{\underline{0}}$ 1·129. (296°). V.D. 9·26 (calc. 8·96). Prepared by the action of C_2H_4 upon *p*-di-chloro-benzene in presence of Al_2Cl_6. Liquid. Sol. 90 p.c. alcohol (46 vols.) and benzene (6 vols.) (Istrati, *A. Ch.* [6] 6, 485).

Tri-chloro-ethyl-benzene $C_6H_2Cl_3(C_2H_5)$. A mixture of these bodies is formed by treating $C_6H_3Cl_3$ [1:2:4] with C_2H_4 in presence of Al_2Cl_6 (Istrati, *A. Ch.* [6] 6, 490). Liquid. S.G. $^{\underline{0}}$ 1·389. (244°). V.D. 7·24. Sol. benzene ($3\frac{1}{2}$ vols.) and alcohol (17 vols.).

Tri-chloro-di-ethyl-benzene $C_6HCl_3(C_2H_5)_2$. A mixture of these bodies is obtained by treating $C_6H_3Cl_3$ [1:2:4] with C_2H_4 in presence of Al_2Cl_6. Liquid, greases paper. S.G. $^{\underline{0}}$ 1·305. (269°). V.D. 8·37. Sol. benzene (5 vols.) and alcohol (26 vols.).

Tri-chloro-tri-ethyl-benzene $C_6Cl_3(C_2H_5)_3$. S.G. $^{\underline{0}}$ 1·240. (291°). V.D. 8·42 (calc. 8·19). Prepared by passing C_2H_4 into a mixture of Al_2Cl_6 and $C_6H_3Cl_3$ [1:2:4]. Oil. Sol. benzene (5 vols.) and alcohol (41 vols.).

Tetra-chloro-ethyl-benzene $C_6HCl_4(C_2H_5)$. S.G. $^{\underline{0}}$ 1·548. (c. 272°). V.D. 7·99 (calc. 8·47). Formed by treating $C_6H_2Cl_4$ [1:3:4:5] with C_2H_4 in presence of Al_2Cl_6. Yellowish liquid. Sol. benzene ($5\frac{1}{2}$ vols.) and 90 p.c. alcohol (16 vols.). HNO_3 gives a nitro-derivative [30°] (Istrati, *A. Ch.* [6] 6, 497).

ααωω-**Tetra-chloro-ethyl-benzene** $CHCl_2.CCl_2.C_6H_5$. From di-chloro-styrene and Cl (Dyckerhoff, *B.* 10, 533). Liquid. On distillation it splits up into HCl and $CCl_2:CCl.C_6H_5$.

Tetra-chloro-di-ethyl-benzene $C_6Cl_4(C_2H_5)_2$ [1:3:4:5:2:6]. S.G. ^{15} 1·431. [45°]. (290°). V.D. 8·44 (calc. 9·07). Formed by treating *u*-tetra-chloro-benzene with ethylene and Al_2Cl_6. Prisms (from a mixture of alcohol and benzene). Sol. benzene (7 vols.) and 90 p.c. alcohol (40 vols.) (Istrati, *A. Ch.* [6] 6, 500).

Penta-chloro-ethyl-benzene $C_6Cl_5(C_2H_5)$. [85°]. (c. 297°). S.G. ^{12} 1·720. V.D. 9·57 (calc. 9·29). Prepared by submitting C_6HCl_5, in presence of C_2H_4, to the influence of Al_2Cl_6. The yield is small. HCl gas facilitates the reaction and gives a better yield. White crystals (from alcohol with benzene). V. sol. ether, $CHCl_3$, ligroïn and CS_2. Sol. benzene (9 vols.) and 90 p.c. alcohol (108 vols.). On oxidation with permanganate it gives $C_6Cl_5.CO_2H$, which immediately loses CO_2 forming C_6HCl_5 (Istrati, *A. Ch.* [6] 6, 502).

CHLORO-ETHYL-BENZENE SULPHONIC ACID $C_6H_3Cl(C_2H_5).(SO_3H)$. Formed by heating the mixture of chloro-ethyl-benzenes with H_2SO_4 at 160°. The product appears to consist of several isomerides (Istrati, *A. Ch.* [6] 6, 411).

***Eso*-CHLORO-ETHYL-BENZOIC ACID** $C_6H_3(C_2H_5)Cl.CO_2H$. [115°]. Formed by fusing the ketone $C_6H_3Cl.(C_2H_5).CO.CH_3$ with KOH. White solid; insol. water; begins to sublime at 100°.—BaA'_2: small crystals; insol. cold water (Istrati, *A. Ch.* [6] 6, 424).

CHLORO-ETHYL CARBAMATE $NH_2CO_2C_2H_4Cl$. [115°] (G.); [76°] (N.). Formed by the action of chloro-ethyl-alcohol (glycol chlorhydrin) on chloro-formamide (Gattermann, *A.* 244, 41); and of $ClCH_2.CH_2.O.COCl$ on ammonia (Nemirowsky, *J. pr.* [2] 31, 174). Colourless, strongly refractive plates. Insol. cold, m. sol. hot water.

TETRA-CHLORO-DI-ETHYL CARBONATE $(C_2H_3Cl_2)_2CO_3$. Obtained by passing chlorine into carbonic ether in diffused daylight, ultimately at 80° (Cahours, *A. Ch.* [3] 9, 201). Heavy oil, decomposed by heat.

Per-chloro-di-ethyl carbonate $(C_2Cl_5)_2CO_3$. [86°]. Formed by chlorinating the preceding in direct sunshine (Malaguti, *A. Ch.* [3] 16, 30). Mass of needles. Distils with partial decomposition into CO_2, C_2Cl_6, and $CCl_3.COCl$. Solution in alcohol converts it into carbonic and tri-chloro-acetic ethers. Aqueous KOH gives potassium formate, carbonate, and chloride. Gaseous or aqueous ammonia forms tri-chloro-acetamide (Gerhardt, *Traité*, 1, 166) and a substance melting at 37°.

CHLORO-ETHYL-CROTONIC ACID $C_6H_9ClO_2$. *Chloro-hexenoic acid.* [49·5°]. (215°). S. ·2 at 1°; ·33 at 12°. Formed, together with chloro- and di-chloro-ethyl-aceto-acetic ether by the action of PCl_5 upon ethyl-aceto-acetic ether. Needles (from alcohol or ether). Unpleasant, pungent odour (Isbert, *A.* 234, 188; *cf.* Demarçay, *B.* 10, 1177). Not reduced by sodium amalgam.

Salts. — NaA' deliquescent. — BaA'_2. — CaA'_2 2aq. S. 12 at 19°. Prisms.—AgA'.

Ethyl ether EtA'. (185°).

CHLORO-ETHYL CYANIDE *v. Nitrile of* CHLORO-PROPIONIC ACID.

CHLORO-ETHYLENE C_2H_3Cl *i.e.* $CH_2:CHCl$. *Vinyl chloride.* (−16°). V.D. 2·17. H.F.p. −1880 (*Th.*). H.F.v. −2460. Formed by the action of alcoholic KOH on ethylene chloride $CH_2Cl.CH_2Cl$ (Regnault, *A.* 14, 28), or on ethylidene chloride $CH_3.CHCl_2$ (Wurtz a. Frapolli, *A.* 108, 224). It is a gas which polymerises in sunshine, changing to an amorphous mass, S.G. 1·41, which melts and turns black at 130° (Baumann, *A.* 163, 317). Ammonia has no action on chloro-ethylene below 100°, but at 160° it forms ethylene diamine $CH_2NH_2.CH_2NH_2$ (118°) (Engel, *Bl.* [2] 48, 94). Chlorine unites with $CH_2:CHCl$ in sunshine.

***u*-Di-chloro-ethylene** $CH_2:CCl_2$. (36°). S.G. ^{15} 1·250. V.D. 3·32 (calc. 3·36). Formed by the action of alcoholic KOH on $CH_2Cl.CHCl_2$ (Regnault, *J. pr.* 18, 80; Krämer, *B.* 3, 261), on $CH_2Br.CHCl_2$, or on di-chloro-iodo-ethane (Henry, *C. R.* 97, 1491; 98, 518). Liquid, with alliaceous odour; changes spontaneously into a crystalline isomeride. Chlorine in daylight followed by sunshine gives C_2Cl_6; direct sunshine gives C and HCl. Does not react with KI.

s*-Di-chloro-ethylene** $CHCl:CHCl$. ***Acetylene dichloride. Mol. w. 97. (55°). Formed by passing acetylene into cool $SbCl_5$, the resulting crystalline compound $C_2H_2SbCl_5$ being decomposed by water (Berthelot a. Jungfleisch, *A. Ch.* [4] 26, 472; but *cf.* Sabanejeff, *A.* 216, 262). From $CHClBr.CHClBr$ and zinc in alcoholic solution (S.).

Tri-chloro-ethylene $CHCl:CCl_2$. (88°). From either tetra-chloro-ethane by treatment with alcoholic KOH (Berthelot a. Jungfleisch, *C. R.* 79, 542; *A. Suppl.* 7, 255). From C_2Cl_6, zinc, and dilute H_2SO_4 (E. Fischer, *Z.* 1864, 268). Also from chloral and P_2S_5 at 170° (Paternò a. Oglialoro, *B.* 7, 81). With alcoholic KOH it gives $C_2HCl_2.OEt$. Aqueous or alcoholic NH_3 forms $C_2H_2Cl_2$ (37°) (Engel, *C. R.* 104, 1621). Sodium forms acetylene, ethylene, $C_2H_2Cl_2$, and hydrogen (Brunner a. Brandenburg, *B.* 10, 1496; 11, 61).

Tetra-chloro-ethylene C_2Cl_4 *i.e.* $CCl_2:CCl_2$. (121°) (S.); (125°) (C.). S.G. $\frac{9\cdot4}{4}$ 1·6312 (Schiff, *A.* 220, 97); $\frac{20}{4}$ 1·6190. V.D. 5·82 (calc. 5·75). C.E. (9·4° to 120°) ·001147. μ_β 1·515. R_∞ 49·66 (Brühl). S.V. 114·18. H.F.p. −1150 (*Th.*). H.F.v. −1730. Discovered by Faraday (*T.* 1821, 47) by subjecting C_2Cl_6 to a red heat either alone or in presence of H. Formed also by treating C_2Cl_6 with alcoholic KHS (Regnault, *A. Ch.* [2] 70, 104; 81, 372), with water and granulated zinc (Geuther, *A.* 107, 212), with alcohol and zinc filings, or with aniline (Bourgoin, *Bl.* [2] 23, 344). Formed also by the action of Al_2Cl_6 on chloral (Combes, *A. Ch.* [6] 12, 298). Obtained, together with CCl_4, by heating per-chloro-propane at 300° (Krafft a. Merz, *B.* 8, 1300).

Reactions.—1. *Bromine* forms in sunshine crystals of $C_2Cl_4Br_2$.—2. Dry *chlorine* combines in sunshine forming C_2Cl_6.—3. *Chlorine-water* gives tri-chloro-acetic acid (Kolbe, *A.* 54, 181).—4. Dry *oxygen* has no action even at 120° (Demole a. Dürr, *B.* 11, 1302).—5. *Potash-fusion* gives potassium oxalate and hydrogen (Geuther, *A.* 111, 174).—6. NaOEt at 120° gives $CHCl_2.C(OEt)_3$, $CHCl_2.CO_2Et$, $CH(OEt)_2.CO_2Na$, and $CCl_2:CCl.OEt$ (Geuther, *J.* 1864, 316; *J. pr.* [2] 7, 108).—7. SO_3 at 150° gives $CCl_3.COCl$.

CHLORO-ETHYLENE OXIDE C_2H_3ClO (89°–92°). Formed by heating chloro-iodo-ethylene $CHCl:CHI$, with water (50 vols.) at 150° for

6 days (Sabanejeff, *A.* 216, 268). Liquid. Sl. sol. water.

CHLORO-ETHYLENE CHLORIDE *v.* TRI-CHLORO-ETHANE.

CHLORO-ETHYL ETHER *v.* CHLORO-DI-ETHYL OXIDE.

TRI-CHLORO-ETHYLIDENE-ACETO-ACETIC ETHER *v.* ACETO-ACETIC ACID.

TRI-CHLORO-ETHYLIDENE DIAMINE.

Acetyl derivative $CCl_3.CH(NHAc)_2$. Formed by heating chloral with aceto-nitrile (Hübner, *Z.* 1871, 712; Hepp, *B.* 10, 1651), the equation being: $CCl_3.CHO + 2CH_3CN + H_2O = CCl_3.CH(NH.CO.CH_3)_2$. Needles (from glacial acetic acid). Sol. water and alcohol. Sublimes without melting.

Benzoyl derivative $CCl_3.CH(NHBz)_2$. [257°]. From chloral, benzonitrile, and conc. H_2SO_4. Needles; v. sl. sol. ether.

CHLORO-ETHYLIDENE-ANILINE C_8H_8NCl *i.e.* $CH_2Cl.CH{:}NC_6H_5$. [136°].

Preparation. — Di-chloro-di-ethyl oxide $CH_2Cl.CHCl.OEt$ (1 mol.) is warmed with aniline (2 mols.) in the presence of water. A white powder [87°] is formed, which becomes red [136°] when dried.

Properties.—Red brown powder. Sol. alcohol; it may be a polymeride of the white compound.

Reactions.—1. HNO_2 produces a yellowish grey amorphous body which gives a blue colour with phenol and conc. H_2SO_4.—2. Warmed with aniline it forms phenylamido-ethylidene aniline $C_6H_5N{:}CH.CH_2.NHC_6H_5$ [104°] which yields indole on heating (Berlinerblau a. Polikiev, *M.* 8, 187–189).

CHLORO - ETHYLIDENE DI - CARBAMIC ETHER $C_8H_{15}ClN_2O_4$ *i.e.* $CH_2Cl.CH(NH.CO_2Et)_2$. [147°]. Formed by the action of chlorine on a strong solution of HCN in alcohol; and also by adding conc. aqueous HCl to a solution of carbamic ether in chloro-acetal $CH_2Cl.CH(OEt)_2$ (Bischoff, *B.* 5, 81; 7, 630). Formed also by chlorinating ethylidene di-carbamic ether (Schmid, *J. pr.* [2] 24, 122). Needles (from dilute alcohol). V. sol. ether and alcohol.

Di-chloro-ethylidene di-carbamic ether $CHCl_2.CH(NH.CO_2Et)_2$. [122°]. Formed by passing Cl into an alcoholic solution of $HgCy_2$ (Stenhouse, *A.* 33, 92; Bischoff, *B.* 5, 82). Also by passing chlorine into carbamic ether at 90° (Schmid, *J. pr.* [2] 24, 120). Long needles; v. sol. alcohol and ether.

TRI-CHLORO-ETHYLIDENE-TRI-CHLORO-LACTATE *v.* CHLORALIDE.

CHLORO-ETHYLIDENE GLYCOL, *derivatives of, v.* CHLORO-ALDEHYDE.

TRI - CHLORO - ETHYLIDENE - MALONIC ACID $CCl_3.CH{:}C(CO_2H)_2$.

Ethyl ether Et_2A''. (160°–164°) at 23 mm. From chloral, malonic ether and Ac_2O at 160° (C. M. Thompson, *A.* 218, 169).

TRI-CHLORO-ETHYLIDENE-DI-PHENYL-DIAMINE *v.* TRI-CHLORO-DI-PHENYL-ETHYLIDENE-DIAMINE.

TRI-CHLORO-ETHYLIDENE-QUINALDINE *v.* (*Py.* 3)-QUINOLYL-ACRYLO-TRI-CHLORIDE.

CHLORO - ETHYLIDENE - *p* - TOLUIDINE $C_9H_{10}NCl$ *i.e.* $CH_3.C_6H_4.N.CH.CH_2Cl$. [58°]. Prepared by decomposing di-chloro-ether $CH_2Cl.CHCl.OEt$ with water, and adding *p*-toluidine. Sol. alcohol and ether; forms with aniline or toluidine a compound free from chlorine. Heated with aniline it yields indole (Berlinerblau a. Polikiev, *M.* 8, 190, 191).

DI-CHLORO-ETHYLIDENE-UREA $CO(NH)_2CH.CHCl_2$. From di-chloro-acetic aldehyde and urea (Schiff, *A.* 151, 186). Needles.

Tri-chloro-ethylidene-di-urea $C_4H_7Cl_3N_4O_2$ *i.e.* $CCl_3.CH(NH.CO.NH_2)_2$. Is the chief product of the reaction of chloral-cyanhydrin with urea. White needles. Insol. ordinary solvents (Pinner a. Lifschütz, *B.* 20, 2346).

CHLORO-ETHYL-MALONIC ETHER $C_2H_5.CCl.(CO_2Et)_2$. (228°). S.G. $^{\underline{17}}$ 1·11. Liquid. Prepared by passing Cl into ethyl-malonic ether (Conrad, *B.* 14, 618). By saponification with baryta-water it gives ethyl-tartronic acid.

DI-CHLORO-ETHYL MERCAPTAN $CH_2Cl.CH_2.SCl$(?). S.G. $^{\underline{13}}$ 1·408. Said to be formed from ethylene and SCl_2 (Guthrie, *A.* 113, 275). Pungent oil, sl. sol. ether.

CHLORO-DI-ETHYL OXIDE C_4H_9ClO *i.e.* $CH_3.CHCl.OEt$. *Aldehyde ethylo-chloride.* Mol. w. 108½. (98°).

Formation.—1. The first product of the action of chlorine on ether (Lieben, *A.* 111, 121; 146, 180; Abeljanz, *A.* 164, 197; Jacobsen, *B.* 4, 215).—2. By the action of HCl on an alcoholic solution of aldehyde (Wurtz a. Frapolli, *A.* 108, 226; Claus a. Trainer, *B.* 19, 3004).—3. By the action of PCl_5 (1 mol.) on di-ethyl-acetal (1 mol.) (Bachmann, *A.* 218, 39).—4. By the union of aldehyde with EtCl.

Reactions.—1. NaOEt gives acetal.—2. Conc. H_2SO_4 gives $EtHSO_4$, aldehyde and HCl.—3. Cold *water* forms aldehyde, alcohol, and HCl. Water at 80° gives aldehyde (Laatsch, *A.* 218, 36). *Alkalis* act in the same way. Cold *alcohol* has no action, but at 80° aldehyde and EtCl are formed.—4. Decomposes on keeping into HCl and a liquid boiling at 76°.

ω-Chloro-di-ethyl oxide $CH_2Cl.CH_2.OEt$. (108°). S.G. $^{\underline{0}}$ 1·0572. V.D. 3·73 (calc. 3·74). From iodo-di-ethyl oxide by the action of Cl, of $SbCl_5$, or of ICl in presence of water (Henry, *C.R.* 100, 1007). It is not affected by light or by water.

***ωα*-Di-chloro-di-ethyl oxide** $CH_2Cl.CHCl.OEt$. (c. 143°). S.G. $^{\underline{23}}$ 1·174. V.D. 4·93. Obtained by the action of chlorine on ether below 30° (Lieben, *A.* 111, 121; 123, 130; 133, 287; 141, 236; 146, 180; 150, 87; Abeljanz, *A.* 164, 197; *cf.* D'Arcet, *A.* 28, 82; Regnault, *A. Ch.* [2] 71, 392; Malaguti, *A. Ch.* [2] 70, 338; [3] 16, 5, 19). Formed also, together with the preceding, by passing HCl into a mixture of aldehyde and alcohol (Natterer, *M.* 5, 496). Also from vinyl-ethyl oxide $CH_2{:}CH.O.Et$ and Cl.

Reactions.—1. *Water* at 120° gives the compound $CH_2Cl.CH(OH)(OEt)$, together with chloro-acetic aldehyde, glycollic aldehyde, alcohol and HCl.—2. Conc. H_2SO_4 produces $EtHSO_4$, chloro-acetic aldehyde, and HCl.—3. With conc. *potash* it forms chloro-aldehyde alcoholate and its anhydride, and also 'oxychloro-ether,' $CH_2OH.CH_2Cl.OEt$ (151°–155°). This latter body is split up by conc. H_2SO_4 into HCl, alcohol and glycollic aldehyde (?), $CH_2OH.CHO$.—4. NaOEt gives chloro-acetal $CH_2Cl.CH(OEt)_2$ and $CH_2(OEt).CH(OEt)_2$.—5. AgOAc gives $CH_2Cl.CH(OEt)(OAc)$ (Bauer, *A.* 134, 176).—

6. Dry metallic *zinc* acts vigorously, producing HCl, $ZnCl_2$, EtCl, alcohol, $CH_2Cl.CHO$, and a condensation product of the alcoholate of the latter, $C_8H_{16}Cl_2O_2$ (Wislicenus, *A.* 226, 271).—7. *Zinc in presence of water* produces aldehyde, Et_2O, alcohol and chloro-aldehyde, besides small quantities of crotonic-aldehyde, chloro-acetal, β-oxy-chloro-ether ($CH_2OH.CHCl.OEt$) and $(CH_2Cl.CH(OEt))_2O$ (W.).—8. In ethereal solution with $ZnEt_2$ it forms $CH_2Cl.CHEt.OEt$, 'ethyl chloro-ether' (ethyl chloro-butyl oxide). 9. Excess of $ZnEt_2$ gives ethyl hexyl-ether, $CH_2Et.CHEt.OEt$.—10. With $ZnMe_2$ it gives $CH_2Cl.CHMe.OEt$, *i.e.* ethyl chloro-isopropyl ether.—11. Di-chloro-di-ethyl oxide (25 g.) heated with *aniline* (50 g.) and water forms indole (Berlinerblau, *M.* 8, 180).—12. *Phenol* forms $C_2H_3(C_6H_4OH)_3$ (Wislicenus a. Reinhardt, *A.* 243, 151).—13. (α)-*Naphthol* forms amorphous $C_2H_3(C_{10}H_6OH)_3$. (β)-naphthol gives crystalline plates of $C_{22}H_{15}ClO$ [174°] (Wislicenus a. Zwanziger, *A.* 243, 165).—14. *Resorcin*, *Pyrocatechin*, and *Hydroquinone* form compounds of the form $C_2H_3(C_6H_3O_2H_2)_3$ (Wislicenus a. Siegfried, *A.* 243, 171).—15. *Thiourea* forms thiazoline (Hantsch a. Traumann, *B.* 21, 938).

Di-chloro-di-ethyl oxide $(CH_3.CHCl)_2O$. *Ethylidene oxychloride.* (117°). S.G. $^{14\cdot5}$ 1·136. V.D. 5·08 (calc. 4·95). From dry aldehyde cooled by a freezing mixture by passing dry HCl into it. The product is dried with $CaCl_2$ and distilled (Lieben, *C. R.* 46, 662; Kessel, *A.* 175, 44; 176, 44; Geuther, *A.* 218, 16).

Reactions.—1. *Water* on warming decomposes it into HCl and aldehyde.—2. *Alcohol* forms chloro-diethyl oxide $(CH_3.CHCl)_2O + 2HOEt = 2CH_3.CHCl(OEt) + H_2O$.—3. NaOEt converts it (in ethereal solution) into aldehyde-resin, acetal, and alcohol.—4. Alcoholic *sodium ethylate* forms, besides the same products, a liquid $(CH_3CH.OEt)_2O$ (153° cor.) S.G. ^{14} ·891. This is sparingly sol. water. It decomposes in a few days into acetal and aldehyde: $(CH_3CH.OEt)_2O = CH_3.CH(OEt)_2 + CH_3.CHO$.—5. Dry NaOEt gives $CH_3.CH(OEt).O.CHCl.CH_3$ (146°), a liquid, decomposed by hot water (Hanriot, *A. Ch.* [5] 25, 223).—6. MeOH and NaOMe form similarly $(CH_3CH.OMe)_2O$ (126°-127°). S.G. $^{12\cdot5}$ ·953. This also has an aromatic smell and splits up like the foregoing, though more slowly, into dimethyl acetal and aldehyde.—7. *Sodium succinate* gives $O(CHMe.OCO)_2C_2H_4$ (Geuther, *A.* 226, 228).—8. *Zinc ethyl* produces di-butyl oxide $(CH_3.CHEt)_2O$.

Tri-chloro-di-ethyl oxide $CHCl_2.CHCl.OEt$. (157°) (G.); (168°) (K.). From chloro-vinyl ethyl oxide and Cl (Godefroy, *C. R.* 102, 869). Also from di-chloro-acetal and PCl_5 (Krey, *J.* 1876, 475). Occurs in the product of chlorination of ether. Fuming liquid; with NaOEt it gives $CHCl_2.CH(OEt)_2$. Conc. aqueous KOH gives $CCl_2{:}CH.OEt$ (145°).

Tetra-chloro-di-ethyl oxide $CCl_3.CHCl.OEt$. Mol. w. 212. (190°) (P. a. P.); (c. 183°) (G.). S.G. ^{0} 1·437; ^{15} 1·418.

Formation.—1. From chlorine and ether at 90° in the dark.—2. From chloral alcoholate and PCl_5 (Henry, *B.* 4, 101, 435; Paternò a. Pisati, *J.* 1872, 303; *G.* 2, 333).—3. From di-chloro-vinyl ethyl oxide $CCl_2{:}CH.OEt$ and chlorine (Godefroy, *C. R.* 102, 869).

Reactions.—1. Conc. H_2SO_4 gives chloral, HCl, and alcohol.—2. Heated with *alcohol* it gives tri-chloro-acetal $CCl_3CH(OEt)_2$.—3. With dilute (10 p.c.) *alcoholic potash* it gives trichloro-vinyl-ethyl oxide $CCl_2{:}CCl.O.Et$.—4. H_2S gives $C_4H_8S_2O$ [123°] and $C_4H_8Cl_2SO$ [72°] (Malaguti, *A.* 32, 29).

Penta-chloro-di-ethyl oxide $CCl_3.CCl_2.OEt$. (190°-210°). S.G. 1·65.

Formation.—1. The final product of the action of chlorine on ether in the dark (Jacobsen, *B.* 4, 217).—2. From $CCl_2{:}CCl.OEt$ and Cl (Busch, *B.* 11, 445). It is partly decomposed on boiling.

Penta-chloro-di-ethyl oxide $CCl_3.CHCl.O.CH_2.CH_2Cl$. (235°). S.G. ^{8}: 1·577. From PCl_5 and $CCl_3.CH(OH).O.CH_2.CH_2Cl$, a compound of chloral and glycolic chlorhydrin (Henry, *B.* 7, 763).

Hexa-chloro-di-ethyl oxide $(CHCl_2.CHCl)_2O$. (250°). From PCl_5 and the hydrochloride of di-chloro-aldehyde (Paternò a. Pisati, *G.* 1, 461).

Octo-chloro-di-ethyl oxide $C_4H_2Cl_8O$. Formed by the action of Cl on aldehyde hydrochloride in sunlight.

Crystals, smelling like camphor, may be sublimed (Roth, *B.* 8, 1017).

Per-chloro-di-ethyl oxide $C_4Cl_{10}O$. [69°]. S.G. ^{15} 1·900. Formed by the action of chlorine in sunlight on ether (Regnault, *A.* 34, 27; Malaguti, *A. Ch.* [3] 16, 4). Dimetric octahedra (Nicklès, *A. Ch.* [3] 22, 28). Splits up on heating into C_2Cl_6 and trichloro-acetyl chloride.

CHLORO-ETHYL-OXY-TOLUQUINOLINE *v.* CHLORO-OXY-METHYL-ETHYL-QUINOLINE.

ω-**CHLORO-DI-ETHYL-DI-PHENYL-ETHANE** $C_{18}H_{21}Cl$ *i.e.* $CH_2Cl.CH(C_6H_4Et)_2$. (c. 268°). From ethyl-benzene, $CH_2Cl.CHCl.OEt$, and H_2SO_4 (Hepp, *B.* 7, 1414). On distillation it gives HCl and $C_{18}H_{20}$.

Eso-**CHLORO-ETHYL-PHENYL METHYL KETONE** $C_6H_3EtCl.CO.CH_3$. Formed, together with the two chloro-phthalic acids, by oxidising chloro-di-ethyl-benzene with chromic mixture (Istrati, *A. Ch.* [6] 6, 421). Liquid; not attacked by boiling alcoholic KOH, but converted into chloro-ethyl-benzoic acid by potash-fusion.

CHLORO-TETRA-ETHYL-PHOSPHONIUM CHLORIDE $(ClCH_2.CH_2)PEt_3Cl$. From PEt_3 and ethylene chloride in the cold (Hofmann, *A. Suppl.* 1, 276). Needles. Moist Ag_2O converts it into an oxy-ethyl base $CH_2(OH).CH_2.PEt_3OH$.

Salt.—$(C_2H_4Cl.PEt_3Cl)_2PtCl_4$. Orange needles.

CHLORO-ETHYL-PROPYL-GLYOXALINE $C_8H_{13}ClN_2$. *Chlor-oxal-propyline* (236° cor.). V.D. = 5·65 (obs.). S.G. ^{16} 1·09. From di-propyl oxamide by PCl_5. Oil. V. sl. sol. water, miscible with alcohol, ether, or $CHCl_3$. On reduction with HI it gives ethyl-propyl-glyoxaline (Wallach a. Schulze, *B.* 13, 516; 14, 423; *A.* 214, 312).

Salts.—$(B'HCl)_2PtCl_4$.—B'HI.—B'_2AgNO_3: needles.

(*Py.* 3, 2)-**CHLORO-ETHYL-QUINOLINE**

$C_{11}H_{10}ClN$ *i.e.*  [73°].

$$C_6H_4\left\langle\begin{matrix}CH=C(C_2H_5)\\ | \\ N\ \ =CCl\end{matrix}\right.$$

Prepared by the action of PCl_5 on ethyl-hydro-carbostyril (Baeyer a. Jackson, *B.* 13, 120). Insol. water, v. sol. other solvents. Volatile with steam. Weak base.—$(B'HCl)_2PtCl_4$. V. sol. alcohol, decomposed by water.

Chloro - ethyl(?) - isoquinoline $C_{11}H_{10}NCl$. [c. 80°]. Formed by boiling the di-chloro-derivative [166°] with HI and P. Colourless crystals. By heating with HI and P to 200° it is completely dechlorinated (Gabriel, *B.* 20, 1206).

Di-chloro-ethyl(?)-isoquinoline $C_{11}H_9NCl_2$ probably $C_6H_4<\begin{matrix}C(C_2H_5):CCl\\ \quad|\\ CCl=N\end{matrix}$ [166°]. Formed by heating the imide of phenyl-di-methyl-carboxylic acid $C_6H_4<\begin{matrix}CMe_2.CO\\ \quad|\\ CO.\;NH\end{matrix}$ with $POCl_3$; if the product is a derivative of ethyl-isoquinoline an isomeric change must have occurred during the reaction. Long colourless needles. By HI and P it is first reduced to the mono-chloro-derivative [80°] and then to the ethyl(?)-isoquinoline [65°] (Gabriel, *B.* 20, 1206).

DI-CHLORO-DI-ETHYL SULPHIDE $(CH_2Cl.CH_2)_2S$. (217°). Formed by the action of PCl_5 on $S(CH_2.CH_2OH)_2$ obtained from glycol chlorhydrin and K_2S (V. Meyer, *B.* 19, 3259; 20, 1729). Oil. Very poisonous and violently inflames the skin (difference from di-ethyl sulphide).

Tetra-chloro-di-ethyl sulphide $(C_2H_3Cl_2)_2S$. (167°–172°). S.G. $\frac{1}{2}$? 1·547. A yellow oil formed by passing chlorine into di-ethyl sulphide, which is at first kept cool and in the shade (Riche, *A.* 92, 358). There appear also to be formed $(C_2H_2Cl_3)_2S$ (189°–192°), $(C_2HCl_4)_2S$ (217°–222°) and $(C_2Cl_5)_2S$ (?).

Di-chloro-di-ethyl di-sulphide $(CH_2Cl.CH_2)_2S_2$. S.G. $\frac{1}{0}$ 1·346. From ethylene and Cl_2S_2 at 100° (Guthrie, *A.* 119, 91; 121, 108). Pale yellow oil. Alcoholic KOH gives oily $(CH_2OH.CH_2)_2S$. HNO_3 forms $CH_2Cl.CH_2.SO_3H$ (Spring a. Lecrenier, *Bl.* [2] 48, 629).

Tetra-chloro-di-ethyl di-sulphide $(C_2H_3Cl_2)_2S_2$. S.G. $\frac{1}{1}$ 1·599. Formed by passing ethylene through boiling S_2Cl_2 (G.). Oil.

CHLORO-ETHYL SULPHOCYANIDE $Cl.C_2H_4.CNS$. (203°). Formed by heating $C_2H_4Br_2$ (100 g.), KCNS (66 g.) and alcohol (250 c.c.) with inverted condenser. The product is filtered, distilled to 150° and the residue in the retort cooled in a freezing mixture. $C_2H_4(CNS)_2$ now crystallises out. The liquid portion is distilled (J. W. James, *C. J.* 35, 807, *J. pr.* [2] 20, 352; 31, 411). Formed in the same way from ethylene chloro-bromide (107°–109°) (James, *C. J.* 43, 39; 47, 365).

Properties.—Oil. Smells like mustard oil. Burns with violet flame. Soluble in alcohol and ether. Dissolves in hot water, but separates again on cooling.

Reactions.—1. Fuming HNO_3 converts it into chloro-ethane sulphonic acid, $Cl.C_2H_4.SO_3H$. Ammonia, of course, will convert this into taurine.—2. Alcoholic *potassic sulphocyanide* converts it into $C_2H_4(SCN)_2$.—3. With aqueous Na_2SO_3 in sunlight it forms $C_2H_4(SCN)(SO_3Na)$.

DI-CHLORO-(α)-ETHYL-THIOPHENE $C_4H(C_2H_5)Cl_2S$ (236° cor.). A liquid formed by passing chlorine into cooled 'β'-ethyl-thiophene (Bonz, *B.* 18, 551).

DI-CHLORO-ETHYL-TOLUENE (?). $C_9H_{10}Cl_2$. (365°). Formed, together with propylene and chlorinated cresol by distillation of penta-chloro-thymol (Lallemand, *C. R.* 43, 375).

DI-CHLORO-EUXANTHIC ACID *v.* EUXANTHIC ACID.

DI-CHLORO-FLUORENE $C_{13}H_8Cl_2$. [128°]. Formed by passing chlorine into fluorene (from coal-tar) in chloroform (Hodgkinson a. Matthews, *C. J.* 43, 170). Colourless plates. Oxidised by chromic mixture to di-chloro-di-phenylene ketone [158°].

Tri-chloro-fluorene $C_{13}H_7Cl_3$ [147°]. Formed by leading chlorine into a CS_2 solution of fluorene for a long time (Holm, *B.* 16, 1082). White plates. Sl. sol. alcohol and ether.

Penta-chloro-fluorene di-chloride $C_{13}H_3Cl_7$ [104°]. From di-chloro-fluorene in chloroform by chlorine (H. a. M.). Long needles. CrO_3 converts it into a yellow ketone (?) [104°]. Alcoholic KOH converts it into a red body (? $C_{13}H_5Cl_5$) which is insol. alcohol, but crystallises from chloroform, petroleum or acetic acid [c. 110°]. It is not attacked by HNO_3 or CrO_3.

CHLORO-FLUORESCEÏN
$CO<\begin{matrix}C_6H_3Cl\\ —O—\end{matrix}>C<\begin{matrix}C_6H_3(OH)\\ C_6H_3(OH)\end{matrix}>O$. Formed by heating chloro-phthalic anhydride [97°] with resorcin. V. sl. sol. water and $CHCl_3$. When freshly prepared it is sol. alcohol and ether, but it changes on keeping into an insoluble crystalline form; v. sol. acetic acid; insol. C_6H_6; sol. aqueous KHO, and K_2CO_3 forming a deep red solution, which when diluted shows a fluorescence like that of fluorescein (Graebe a. Rée, *C. J.* 49, 530).

Di-chloro-fluoresceïn. *Hydrate.* $C_6H_2Cl_2:C_2O_2:(C_6H_3(OH)_2)_2$. Formed by heating (β)-di-chloro-phthalic anhydride [151°] with resorcin at 200°. Loses aq when heated. Alkalis form a red solution with green fluorescence (Le Royer, *A.* 238, 357).

Tetra-chloro-fluoresceïn $C_6Cl_4:C_2O_2:(C_6H_4OH)_2O$. Formed by heating resorcin with tetra-chloro-phthalic anhydride (Graebe, *A.* 238, 333). Addition of acids to its solution in NaOH pps. the hydrate or ortho-compound, which at 180° is dehydrated. Insol. ether.

Diacetyl derivative $C_6Cl_4:C_2O_2:(C_6H_4OAc)_2O$.

Hydrate $C_6Cl_4:C_2O_2:(C_6H_4(OH)_2)_2$. Ppd. by adding acids to a solution of the fluoresceïn in aqueous NaOH. Orange needles (from ether); insol. water, sl. sol. alcohol. Its alkaline solution is red with strong green fluorescence like fluoresceïn. At 180° it gives off H_2O.

Chloride $C_6Cl_4:C_2O_2:(C_6H_3Cl)_2O$. [259°].

CHLOROFORM $CHCl_3$. *Tri-chloro-methane.* Mol. w. 119½. [–70°] (Berthelot, *Bl.* [2] 29, 3). (60·9°) at 754·3 mm. (Schiff, *A.* 220, 95); (61·4°) (Thorpe); (62°) (Perkin, *C. J.* 45, 530). S.G. $\frac{11\cdot8}{4}$ 1·5039; $\frac{60\cdot9}{4}$ 1·4081; $\frac{15}{15}$ 1·5009; $\frac{25}{25}$ 1·4849. C.E. (11·8 to 60·9) ·00138 (Schiff); (0°–10°) ·001248 (Thorpe); (0°–50°) ·0013368 (T.); see also Grimaldi, *G.* 17, 18. S. ·987 at 0°; ·775 at 55° (Chancel a. Parmentier, *C. R.* 106, 577). V.D. 4·12 (for 4·12). H.F.p. 24110 (*Th.*). H.F.v. 23530. M.M. 5·559 at 15·3°. S.H. ·233 (Schüller, *P. Suppl.* 5, 116, 192). μ_D 1·451 (Forbes, *P. M.* [3] 35, 94). S.V. 84·6 (Schiff); 85·6 (Ramsay); 84·5 (Thorpe). *Capillarity*: Swan, *C. J.* 1, 174; *P. M.* [3] 33, 36. *Compressibility*: Grassi, *A. Ch.* [3] 31, 437.

Formation.—1. By the action of bleaching-powder on dilute alcohol (Soubeiran, *A. Ch.* [2] 48, 131; Soubeiran a. Mialhé, *A.* 71, 225) or on acetone (Liebig, *A.* 1, 198).—2. By the action of chlorine on marsh-gas in daylight, and ultimately in sunlight (Regnault, *A. Ch.* [2] 71, 380).—3. By passing a mixture of chlorine and methyl chloride through animal charcoal at 250°-350° (Damoiseau, *C. R.* 92, 42).—4. By the action of aqueous potash on chloral (Liebig, *A.* 1, 199).—5. By the action of nascent hydrogen on CCl_4.—6. By boiling tri-chloro-acetic acid with aqueous alkalis (Dumas, *A. Ch.* [2] 56, 115; *A.* 32, 113).—7. From iodoform and PCl_5 (Gautier, *Bl.* [2] 13, 316).—8. From CCl_4, zinc, and dilute H_2SO_4 (Geuther, *A.* 107, 212).

Preparation.—1. By mixing chloral with dilute caustic soda.—2. Bleaching powder (40 pts.), water (100 to 150 pts.), alcohol (4 to 10 pts.), and slaked lime (4 to 10 pts.) are distilled together. The distillate separates into two layers, the lower one being chloroform. This is freed from chlorine by shaking with potash, dried over $CaCl_2$ and rectified (Kessler, *J. Ph.* [3] 13, 162).

Theory of the process.—The bleaching powder is supposed first to convert the alcohol into chloral (*q. v.*), and the lime which is present (or formed) would then split this up into calcic formate and chloroform: $8CaO.Cl_2 + 2C_2H_6O$ $= 2C_2Cl_3HO + 5CaCl_2 + 3CaO + 5H_2O$ $= 2CCl_3H + Ca(CHO_2)_2 + 5CaCl_2 + 2CaO + 4H_2O$.

When alcohol of various strengths is poured on bleaching powder the distillate, which sometimes explodes after shaking well with water, gives an oil which can be separated by fractionating into the following portions:—

Fraction	1 pt. alcohol mixed with pts. of water					
	0	1	2	4	8	
60°-70°	2·4	3·4	56·5	89·1	98·1	per-centage compo-sition of oil.
70°-80°	9·8	12·4	31·2	7·8	1·9	
80°-100°	12·3	31·6	12·2	3·1	—	
100°-150°	21·0	27·5	—	—	—	
150°-160°	50·6	24·9	—	—	—	
160°-180°	4·2	—	—	—	—	

The amount of chloro-acetal (150°-160°) is therefore greatly diminished by diluting the alcohol (Goldberg, *J. pr.* 132, 111). The yield of chloroform is never more than equal in weight to the weight of the alcohol used, this is less than one molecule of chloroform from two molecules of alcohol. Chloroform cannot be prepared from pure methyl alcohol by means of bleaching powder, although it is formed from commercial methyl alcohol (Belohoubek, *A.* 165, 349). Chlorinated compounds are formed by the action of bleaching powder on isopropyl, isobutyl, and iso-amyl alcohols; so that the alcohol used to prepare chloroform should not contain fousel oil (J. Regnault a. E. Hardy, *J. Ph.* [4] 30, 405).

Properties.—Characteristic odour and sweet taste, almost insoluble in water. When pure it is not turned brown by H_2SO_4. Chloroform reduces Fehling's solution, thus: $CHCl_3 + 2CuO + 5KHO$ $= Cu_2O + 3KCl + K_2CO_3 + 3H_2O$ (Baudrimont, *J. Ph.* [4] 9, 410). It dissolves fats and resins. A solution of iodine in chloroform is violet, but bromine forms a red solution. It is anæsthetic (James Simpson, *A.* 65, 121) and antiseptic (Robin, *C. R.* 30, 52; Augendre, *C. R.* 31, 679). When a mixture of chloroform and water is kept at 0° for a long time with frequent shaking a hydrate $CHCl_3$ 18aq separates in long laminæ. It is lighter than chloroform but heavier than water, and melts at 1·6° (Chancel a. Parmentier, *C. R.* 100, 27; *cf.* Sajohelyi a. Ballo, *B.* 4, 160).

Detection.—Chloroform may be distinguished from most other similar chlorinated hydrocarbons by boiling it with alcoholic potash and a primary amine (*e.g.* aniline), when the characteristic disgusting odour of the carbamines will be noticed (Hofmann, *B.* 3, 769). When the vapour of chloroform is passed through a red-hot tube chlorine is liberated, and will turn paper moistened with starch and potassium iodide blue (Ragsky, *J. pr.* 46, 170; Luedeking, *Am.* 8, 358). Chloroform gives a reddish-purple colour (? rosolic acid) when poured upon the hot residue obtained by evaporating an alcoholic solution of phenol mixed with caustic potash (Guareschi, *G.* 3, 401).

Impurities.—Chloroform that is to be used for surgical operations should not give any brown colour when shaken with H_2SO_4 (Gregory, *Pr. E.* 1850, 391; *cf.* Vulpius, *Ar. Ph.* [3] 13, 37; 25, 998). The presence of alcohol causes opalescence when chloroform is mixed with water (Mialhé, *J. Chim. Méd.* [3] 4, 279), and a green colour with chromic mixture (Cottell, *J. Ph.* [3] 13, 359). The reduction of potassium permanganate may also be used as a rough index of the amount of alcohol, aldehyde, and other oxidisable substances present in chloroform (Jolles, *Chem. Zeit.* 11, 786).

Estimation.—By treating a chloroform solution with alcoholic potash the chlorine is obtained as chloride. The conditions for getting a theoretical yield have been determined by De Saint-Martin (*C. R.* 106, 492-496; *cf.* Chancel a. Parmentier, *C. R.* 106, 577).

Reactions.—1. CrO_3 mixture gives $COCl_2$.—2. *Zinc* and dilute H_2SO_4 convert it into CH_2Cl_2 (Geuther, *A.* 107, 212; Richardson a. Williams, *C. N.* 18, 60).—3. *Zinc-dust* converts it in presence of ammonia into methane (Perkin, *C. N.* 18, 106).—4. Boiled with *alcoholic potash* it forms potassium chloride and formate, thus: $CHCl_3 + 4KHO = 3KCl + CHO_2K + 2H_2O$.—5. With *sodic ethylate* it gives orthoformic ether, $CH(OEt)_3$ (Williamson a. Kay, *C. J.* 7, 224).—6. Mixed with ammonia and passed through a red-hot tube it reacts thus: $CHCl_3 + NH_3$ $= CNH + 3HCl$. Aqueous *ammonia* at 220° forms carbonic oxide, ammonium formate, and ammonic chloride, thus: $2CHCl_3 + 7NH_3 + 3H_2O$ $= CO + 6NH_4Cl + HCO_2NH_4$ (André, *C. R.* 102, 553).—7. *Water* at 220° forms CO, formic acid, and HCl.—8. Alcoholic K_2S forms potassium thioformate H.CO.SK (Nicol, *Tr. E.* 29, 531).—9. *Aniline* at 190° gives di-phenyl-form-amidine $C_6H_5NH.CH{:}N.C_6H_5$ (Hofmann, *Pr.* 9, 229).—10. *Bromine* at 200° gives $CBrCl_3$ (Paternò, *G.* 1, 593; Friedel a. Silva, *Bl.* [2] 17, 537).—11. With *bromine* (3 pts.) and *iodine* (1 pt.) at 150° it gives CBr_2Cl [70°] and CBr_4 [76°] (Bolas a. Groves, *C. J.* 24, 770).—12. HNO_3 containing NO_2 forms at 100° a small quantity of chloropicrin (Mills, *C. J.* 24, 641).—13. Conc. HIAq at 125° gives CH_2I_2 (Lieben, *Z.* [2] 4, 713). PH_4I and ZnO give CH_3Cl (Hofmann, *B.* 6, 301).—14. When passed over *red-hot copper* some acetylene is formed (Berthelot, *C. R.* 50, 805).—15. *Potassium amalgam* also forms acetylene (Kletzinsky, *Z.* [2] 2, 127).—16. K_2SO_3 at 170° forms $CH_2(SO_3K)_2$ and $CH(SO_3K)_3$ (Strecker, *Z.* [2] 4, 214).—17. *Sodium* acting on chloroform containing alcohol forms chlorethulmic acid $C_6H_9ClO_2$ (Hardy, *A. Ch.* [3] 65, 340; *C. R.* 54, 470; *cf.* Kern, *C. N.* 31, 121).—18. The *copper-zinc couple* does not act on pure chloroform; in presence of alcohol at 60° methane is evolved, together with a small quantity of acetylene; in presence of water methane is evolved even at 12° (Gladstone a. Tribe, *C. J.* 28, 508).—19. $SbCl_5$ at 100° forms CCl_4 (Lössner, *J. pr.* [2] 13, 418).—20. Electric sparks decompose chloroform forming HCl and C_2Cl_6; in presence of air $COCl_2$ is formed (J. Regnault, *J. Ph.* [5] 5, 504).—21. Potash added to a mixture of *acetone* (1 mol.) and chloroform (1 mol.) forms acetone-chloroform or oxy-isobutyro-tri-chloride $(CH_3)_2C(OH).CCl_3$. There is also formed a liquid isomeride, possibly $CHCl_2.CMe_2.OCl$, (170°). It is a strong poison and yields with benzene and Al_2Cl_6 chloro-di-phenyl-*tert*-butyl alcohol (239°); while with PCl_5 it yields $C_4H_6Cl_2O$ (151°) (Willgerodt a. Genieser, *J. pr.* [2] 37, 362). Potash (8 mols.) acting on chloroform (1 mol.) and acetone (2 mols.) forms $C_{11}H_{20}O_6$ *i.e.* $CMe_2(O.CMe_2.CO_2H)_2$; an acid which, like acetone-chloroform (*q. v.*), is converted into oxy-isobutyric acid by heating with water (Willgerodt, *B.* 20, 2445; *Bl.* [2] 39, 157; Engel, *Bl.* [2] 47, 499; *C. R.* 104, 688).—22. With SO_3 it forms carbonic oxide, $ClSO_3H$ and $Cl_2S_2O_5$ (Armstrong, *Z.* 1870, 247).

Combination.—With aqueous H_2S at 0° it forms a crystalline compound $CHCl_3 2H_2S$ 23aq (Loir, *C. R.* 34, 547; *J.* 1852, 560; Forcrand, *A. Ch.* [5] 28, 12).

CHLORO-FORMIC ACID Cl.CO.OH.

Methyl ether. $Cl.CO_2.Me$. (71° cor.). S.G. $\underline{15}$ 1·236 (Roese, *A.* 205, 228). Formed by the action of $COCl_2$ on methyl alcohol (Dumas, *A.* 10, 277; *A. Ch.* 58, 52; Meyer a. Wurster, *B.* 6, 965). Formed also by the action of chlorine on gaseous methyl formate (Hentschel, *J. pr.* [2] 36, 211). *Preparation.*—To avoid formation of methyl carbonate proceed thus: Phosgene is freed from chlorine by passing through a flask full of pieces of antimony and powdered glass and placed in the water bath. The gas is passed into a few c.c. of chloro-formate of methyl at 0°. Methyl alcohol is added in small portions at a time, waiting each time until the phosgene goes through unabsorbed. Altogether not more than 150 c.c. of methyl alcohol should be used (A. Klepl, *J. pr.* [2] 26, 447). *Properties.*—Heavy oil; readily decomposed by boiling with water. Gives the tri-chloro-methyl ether when chlorine acts on it in sunlight. Intermediate compounds are $C_4H_3Cl_5O_4$ and $C_8H_9Cl_7O_8$. The compound $C_4H_3Cl_5O_4$ (109° cor.) is a very pungent oil, S.G. $\frac{27}{27}$ 1·4741; $\frac{14}{14}$ 1·4786. It is decomposed by water into formic aldehyde, $2CO_2$, and CO; while aniline forms $C_4H_3Cl_3(NPhH)_2O_4$ [45°]; and fusion with NaOAc yields methylene diacetate (166°). The other compound, $C_8H_9Cl_7O_8$ or $C_8H_7Cl_5O_8$, (181° cor.), S.G. 1·52, is a liquid, slowly decomposed by boiling water into CO, CO_2, HCl, and formic aldehyde (Hentschel, *J. pr.* [2] 36, 468).

Tri-chloro-methyl ether CCl_3A'. (128° cor.). S.G. $\underline{11}$ 1·653. V.D. 94·3 (calc. 99). Formed by chlorinating methyl formate in sunlight. Liquid; inflames the skin. Above 300° it changes into the isomeric $COCl_2$; this change takes place slowly even on boiling. At a dull red heat it splits up into CCl_4 and CO_2. Al_2Cl_6 decomposes it in the same way (Hentschel, *J. pr.* [2] 36, 99, 305). *Reactions.*—1. Like $COCl_2$, it acts on NaOAc forming NaCl, CO_2, and Ac_2O.—2. MeOH forms an oil, possibly $CCl_3O.CO.OMe$; it boils at 164° being split up into $COCl_2$ and $Cl.CO_2Me$.—3. Dry and aqueous *ammonia* forms urea but not tri-chloro-acetamide.—4. *Aniline* forms di-phenyl-urea and phenyl cyanate.—5. *Benzene* and Al_2Cl_6 give $(C_6H_5)_3CCl$.—6. *Phenol* gives $C_6H_5O.CO.Cl$.

Ethyl ether $Cl.CO_2Et$. Mol. w. 108$\frac{1}{2}$. (94°). S.G. $\underline{15}$ 1·139. V.D. 3·82. *Preparation.*—By passing $COCl_2$ into well-cooled alcohol (Dumas, *A. Ch.* [2] 54, 226; Cloez, *A. Ch.* [3] 17, 303; Cahours, *A. Ch.* [3] 19, 346; Klepl, *J. pr.* [2] 26, 448; Wilm a. Wischin, *A.* 147, 150); or by dropping alcohol into liquid $COCl_2$ standing in a freezing-mixture (Hentschel, *B.* 18, 1177). *Properties.*—Pungent liquid; decomposed by hot, but not by cold, water. *Reactions.*—1. With *alcohol* it forms carbonic ether, reacting thus: $ClCO_2Et + HOEt = EtO.CO_2Et + HCl$. — 2. With *sodium* it reacts in this way: $2ClCO_2Et + Na_2 = 2NaCl + CO + CO_3Et_2$.—3. With $ZnMe_2$ it reacts in the following manner: $2ClCO_2Et + ZnMe_2 = ZnCl_2 + 2CO_2 + 2C_2H_4 + 2CH_4$ (Butlerow, *Z.* 1863, 484).—4. With *ammonia* it forms carbamic ether, $NH_2.CO_2Et$.—5. Al_2Cl_6 splits it up into CO_2 and EtCl.—6. *Benzene* and Al_2Cl_6 give ethyl-benzene (Rennie, *C. J.* 41, 33).—7. $ZnCl_2$ gives CO_2, EtCl, HCl, and ethylene (Ulsch, *A.* 226, 281).—8. *Sodium amalgam* converts it into formic acid (Geuther, *A.* 205, 225).—9. $NaOC_6H_5$ gives $(C_6H_5O)CO(OEt)$ (Fatianoff, *Z.* 1864, 77).—10. Na_2S gives $S(CO_2Et)_2$ (V. Meyer, *B.* 2, 297).—11. *Potassium cyanate* forms the following crystalline bodies: (*a*) $C_{12}H_{15}N_3O_9$ or $C_3N_3O_3(CO_2Et)_3$ [119°]; (*b*) $C_{11}H_{15}N_3O_7$ or $C_3N_3O_3Et(CO_2Et)_2$ [123°]; (*c*) $C_{10}H_{15}N_3O_5$ or $C_3N_3O_3Et_2(CO_2Et)$ [107°]; (*d*) $NH(CO_2Et)_2$ [50°]; and (*e*) $C_3N_3O_3Et_3$ (Wurtz a. Henninger, *C. R.* 100, 1419; *Bl.* [2] 44, 26).—12. With KNCS in presence of alcohol it forms carbonic ether and allophanic ether (Wilm, *A.* 192, 243): $2Cl.CO_2Et + 2KNCO + 3HOEt = 2KCl + 2Et_2CO_3 + C_2H_3N_2O_3Et$.—13. With *thio-urea* it forms $NH_2.CS.NHCO_2Et,HCl$ [117°] (Pawlewski, *B.* 21, 401).—14. With *di-phenyl-thio-urea* it forms di-phenyl-thio-allophanic acid $NHPh.CS.NPh.CO_2Et$.—15. With *phenyl-thio-urea* it forms phenyl-allophanic acid $NHPh.CS.NH.CO_2Et$.—16. With *acetyl-phenyl-thio-urea* it forms α-phenyl-thio-allophanic acid $NH_2CS.NPh.CO_2Et$.—17. *Cyanethine* forms cyanethine carboxylic acid (E. v. Meyer a. Schöne, *J. pr.* [2] 30, 123).—18. *Quinoline* forms ethyl-quinoline: $C_9H_7N + ClCO_2Et = C_9H_6EtNHCl + CO_2$ (M. a. S.).

Chloro-ethylic ether $Cl.CO_2.CH_2.CH_2Cl$. (150°-160°). From glycolic chlorhydrin and $COCl_2$ in the cold (J. Nemirowsky, *J. pr.* [2] 31, 173). The product is mixed with K_2CO_3 and extracted with ether. Colourless, fuming, pungent liquid, insol. water, sol. alcohol and ether. *Reactions.*—1. Not decomposed by boiling *water*. 2. Converted by boiling dilute *potash* into glycol, potassium chloride, and potassium carbonate.—3. Converted by *ammonia* into the carbamate of chloro-ethyl, as follows: $Cl.CO.O.C_2H_4Cl + 2NH_3 = NH_3,HCl + H_2N.CO.O.C_2H_4Cl$.—4. With *aniline* it reacts, forming the corresponding compound $NPhH.CO_2C_2H_4Cl$ (phenyl-carbamic acid).

Propyl ether $ClCO_2Pr$. (115° cor.). S.G. ^{15} 1·09. Liquid; more stable than methyl ether (Roese, *A.* 205, 229).

Isopropyl ether $ClCO_2Pr$. (95°). S.G. ^{4} 1·144 (Spica, *G.* 17, 168). Gives with NH_3 isopropyl carbamate $NH_2.CO_2Pr$ [37°].

Isobutyl ether $ClCO_2C_4H_9$. (129° cor.). S.G. ^{15} 1·053 (Roese; *cf.* Mylius, *B.* 5, 972). Ammonia converts it into isobutyl carbamate $NH_2.CO_2C_4H_9$ [55°].

Amyl ether $Cl.CO_2C_5H_{11}$. (153°) (S.); (154° cor) (R.). S.G. ^{15} 1·032. From $COCl_2$ and amyl alcohol (Schöne, *J. pr.* [2] 32, 246).

Phenyl ether $Cl.CO_2C_6H_5$. (187°). From the tri-chloro-methyl ether and NaOPh (Hentschel, *J. pr.* [2] 36, 316).

Amide $Cl.CO.NH_2$. [50°]. (62°). Formed by passing dry $COCl_2$ into NH_4Cl at 400° (Gattermann a. Schmidt, *B.* 20, 858). Flat needles, with unpleasant odour. Changes on keeping into cyamelide with evolution of HCl. Decomposed by water into CO_2 and NH_4Cl. With toluene and Al_2Cl_6 it gives the amide of *p*-toluic acid; other aromatic hydrocarbons and phenol ethers act similarly. Amines yield alkyl-ureas. Aqueous NaOH forms cyanic acid. Alcohols in small quantities form allophanic ethers, in excess they give carbamic ethers.

Methylamide $Cl.CO.NHMe$ '*Methyl-urea-chloride.*' [90°]; (94°); colourless plates. Obtained by passing carbonyl chloride $COCl_2$ over dry methylamine hydrochloride heated to 140°. Distilled over lime it yields methyl cyanate OC:NMe. Decomposed by water.

Ethylamide $Cl.CO.NHEt$ '*Ethyl-urea-chloride.*' (92°); colourless liquid. Obtained by passing $COCl_2$ over dry ethylamine hydrochloride heated to 250°–270°. Distilled over lime it yields ethyl cyanate OC:NEt. On conversion into vapour it dissociates into ethyl cyanate and HCl, which recombine on cooling. In most of its reactions it gives the same products as ethyl cyanate (Gattermann a. Schmidt, *B.* 20, 118; *A.* 244, 34).

Di-methyl-amide $Cl.CO.NMe_2$. Colourless liquid. Sol. C_6H_6, ether, and CS_2. Prepared by the action of carbonyl chloride ($COCl_2$) on dimethylamine. Is slowly decomposed by water into CO_2 and $NHMe_2HCl$ (Michler a. Escherich, *B.* 12, 1162).

CHLORO-FORMYL-TRICARBOXYLIC ACID *v.* CHLORO-METHANE-TRICARBOXYLIC ACID.

CHLORO-FUMARIC ACID $C_2HCl(CO_2H)_2$. [191°].

Preparation.—1. Chlorine is passed to saturation into succinyl chloride. Methyl alcohol is added to the product as long as HCl escapes. The liquid is then boiled. On cooling, methyl chloro-fumarate, [102°], separates. The filtrate is poured into water, when a further quantity of this body is thrown down. HCl at 140° decomposes the ether forming the acid (Kauder, *J. pr.* [2] 31, 24).—2. Tartaric acid (50 g.) and PCl_5 (275 g.) are heated with inverted condenser. The product is distilled to 130° and the residue mixed with water. The solution is shaken with ether and the ether evaporated (Perkin a. Duppa, *A.* 115, 105; 129, 373; *C. J. Proc.* 4, 75).

Properties.—Clumps, from alcohol and benzene. V. sol. water, alcohol, and ether, sl. sol. benzene and ligroïn. May be sublimed unaltered.

Constitution.—Perkin considers it to be a derivative of fumaric acid because it is very soluble in water. The fact that it sublimes without forming an anhydride would indicate that it is a derivative of maleïc acid (Kauder).

Reactions.—1. *Sodium amalgam* forms succinic acid (Perkin, *A.* 129, 375).—2. Dissolved in cold water and the equivalent of *aniline* added it gives a crystalline pp. of the acid aniline salt, $CO_2H.CH.CCl.CO_2H.NH_2.Ph$. [178°]. An aqueous solution may be kept for weeks without undergoing any change. On boiling the aqueous solution, it behaves like the corresponding bromo-fumarate, although less readily (Michael, *Am.* 9, 180).

Salts.—KHA″. Transparent prisms.—BaA″ 3aq. Clumps.—Ag_2A''.

Methyl ether. Me_2A''. (224°).

Ethyl ether. Et_2A''. (245°). S.G. ^{20} 1·178. From tartaric ether and PCl_5 (Henry, *A.* 156, 178; Claus, *A.* 191, 80).

Amic ether $C_2HCl(CO_2Et)(CONH_2)$. [102°]. From chlorofumaric ether and alcoholic NH_3 (Claus a. Voeller, *B.* 14, 150). Tables.

Imide C_4HClO_2NH. [131°]. Large colourless plates. Sol. water, alcohol and ether. Formed by chlorination of succinimide (Ciamician a. Silber, *B.* 16, 2394).

Chloro-fumaric acid $C_2HCl(CO_2H)_2$ [178°]. (c. 190°). White pp. consisting of microscopic needles. V. sol. alcohol, water, and ether. Formed by the combination of acetylene-di-carboxylic acid with HCl.

Salts.—$A''K_2$: large sparingly soluble prisms.—$A''Ag_2$ aq: fine crystalline pp.—A″Pb 2aq: amorphous pp. becoming crystalline (Baudrowski, *B.* 15, 2695).

V. also CHLORO-MALEÏC ACID.

TETRACHLOROGALLEÏN $C_{20}H_{10}Cl_4O_8$. From tetra-chloro-phthalic anhydride and pyrogallol at 200° (Graebe, *A.* 238, 337). At 180° it gives off 2aq becoming $C_{20}H_6Cl_4O_7$.

CHLOROGENINE *v.* ALSTONINE.

β-CHLORO-GLUTACONIC ACID $HO_2C.CH:CCl.CH_2.CO_2H$. [129°]. Formed by the action of PCl_5 (16 pts.) upon acetone-di-carboxylic ether $CO(CH_2CO_2Et)_2$ (5 pts.) at 100°, and saponification of the ether with conc. HCl; yield: 50–60 p.c. of the theoretical. The reaction is probably due to the intermediate formation of $CCl_2(CH_2CO_2Et)_2$. White needles (chloroform) or plates (hot benzene). V. sol. water, alcohol, and ether, less in chloroform, insol. cold benzene. By zinc-dust and acetic acid it is reduced to glutaconic acid [132°]; by sodium amalgam to glutaric acid. By alcoholic KOH it is converted into glutinic acid $HO_2C.C:C.CH_2.CO_2H$ (Burton a. Pechmann, *B.* 20, 145).

DI-CHLORO-GLUTAZINE *v.* DI-CHLORO-DI-OXY-AMIDO-PYRIDINE.

TRI-CHLORO-ISOGLYCERIC ACID *v.* TRI-CHLORO-PYRUVIC ACID.

DI-CHLORO-GLYCOCOLL *v.* DI-CHLORO-AMIDO-ACETIC ACID.

DI-CHLORO-GLYCOLLIC ACID. The dialkyl ethers $CCl_2(OR').CO_2R'$ of this acid are the primary products of the action of PCl_5 upon oxalic ethers. On distillation under ordinary atmospheric pressure they split off alkyl chlorides, and are converted into the chloro-glyoxylic ethers $Cl.CO.CO_2R'$ (Anschütz, *B.* 19, 2158).

Di-n-propyl ether $CCl_2(OPr).CO_2Pr$: (111° at 12mm.); colourless liquid. Formed by the action of PCl_5 upon mono-propyl oxalate $C_2O_2(OH)(OPr)$.

Di-isoamyl ether $CCl_2(OC_5H_{11}).CO_2C_5H_{11}$: (152° at 13mm.); colourless liquid. Formed by the action of PCl_5 upon mono-isoamyl oxalate (Anschütz a. Schönfeld, *B.* 19, 1443).

DI-CHLORO-GLYCOLLO-NITRILE $CCl_2(OH).CN$.

Methyl derivative $CCl_2(OMe)CN$. (149°). S.G. 1·39. From di-chloro-acetonitrile and NaOMe (Bauer, *A.* 229, 168). Pleasant smelling liquid, nearly insol. water, but slowly decomposed by it. V. sol. alcohol, ether, and light petroleum. Changes on keeping into a solid isomeride.

Ethyl derivative $CCl_2(OEt)CN$. (161°). S.G. $\underline{15\cdot5}$ 1·339. V.D. 153·24. Polymerises forming a white solid. [171°].

Propyl derivative $CCl_2(OPr)CN$. (183°). S.G. $\underline{15\cdot5}$ 1·238. V.D. 174.

Isobutyl derivative $CCl_2(OC_4H_9)CN$. (196°). S.G. $\underline{15\cdot5}$ 1·123.

These bodies combine with $PtCl_4$, forming compounds such as $CCl_2(OEt)CNPtCl_4$ (Bauer, *A.* 229, 182).

They are acted upon by dry HBr with formation of tri-chloro-aceto-nitrile, probably as a result of these reactions:

(i.) $CCl_2(OMe)CN + HBr = MeBr + CCl_2(OH)CN$.

(ii.) $CCl_2(OH)CN = HCl + Cl.CO.CN$.

(iii.) $CCl_2(OH)CN + HCl = CCl_3.CO.NH_2$ (Bauer, *A.* 229, 192).

So also dilute H_2SO_4 converts $CCl_2(OMe)CN$ into CCl_3CO_2Me and $CCl_2(OEt)CN$ into CCl_3CO_2Et.

CHLORO-GLYOXIM $C_2H_3ClO_2N_2$ *i.e.* $CCl(NOH).CH(NOH)$. [151°]. Formed by the action of hydroxylamine on chloral-hydrate (Nägeli, *B.* 16, 499). Glistening prismatic needles. Sol. water and alcohol.

CHLORO-GLYOXYLIC ETHER $Cl.CO.CO_2Et$. *Ethoxy-oxalyl chloride.* (131°). S.G. $\underline{16}$ 1·216. V.D. 4·68 (calc. 4·71). Prepared by distilling oxalic ether with PCl_5 (V.v. Richter, *B.* 10, 2228; *C. C.* 1878, 446; *cf.* Henry, *B.* 4, 599).

Properties.—Fuming liquid; decomposed by water with formation of oxalic acid. Alcohol gives oxalic ether. Alcoholic NH_3 gives oxamic ether. Aniline forms $CO_2Et.CO.NPhH$.

Reactions.—1. *Zinc ethyl*, followed by water, forms oxy-hexoic ether $CEt_2(OH).CO_2Et$ (Henry, *B.* 5, 949).—2. With *urea* it gives ethyl oxalurate, $NH_2.CO.NH.CO.CO_2Et$ (Henry, *B.* 4, 599; Salomon, *B.* 9, 376).—3. With $HgPh_2$ it gives phenyl-glyoxylic acid (Claisen a. Morley, *B.* 11, 1596).—4. With *di-methyl-aniline* it gives di-methyl-amido-phenyl-glyoxylic acid.—5. With *di-phenyl-thiourea* dissolved in benzene it reacts vigorously, giving off CO_2 and ethyl chloride and forming aniline and a compound which is probably **thio-carbanilido-thio-oxanilide** $NPhH.CS.NPh.CO.CS.NPhH$ (v. Stojentin, *J. pr.* [2] 32, 2). This body melts at [231°]. It dissolves in ether, sparingly in alcohol, not at all in water. It exhibits the following *reactions*: (*a*) Warmed with alcoholic $AgNO_3$ it forms Ag_2S and di-phenyl-parabanic acid, [204°], $CO\left\langle\begin{array}{l}NPh-CO\\ \qquad\;\; |\\ NPh-CO\end{array}\right.$. (*b*) Forms a red solution in aniline, which when warmed with dry alcohol and $AgNO_3$ forms oxalyl-tri-phenyl-guanidine, $C(NPh)\left\langle\begin{array}{l}NPh.CO\\ \qquad\; |\\ NPh.CO\end{array}\right.$ [230°]. (*c*) Fuming HNO_3 forms a compound $C_{15}H_8N_4SO_5$. It melts at [235°], is insol. ether, benzene, CS_2, and light petroleum, and is readily decomposed by aqueous NaOH, *p*-nitraniline being formed. (*d*) Alcoholic NH_3 converts it into $C_{14}H_{18}N_4O_3$, a body which crystallises from alcohol in white needles, [220°], and which is itself converted by fuming HNO_3 into another body, $C_{13}H_{14}N_5O_6$, sparingly soluble in water or alcohol, [235°].—6. With *phenyl thiurea*, dissolved in boiling benzene, it acts thus: $2NH_2.CS.NPhH + ClCO.CO_2Et = NH(CS.NPh)_2C_2O_2 + NH_3 + EtCl + H_2O$. The product is **oxalyl-di-phenyl-di-thio-biuret.** It forms slender needles (from alcohol) [215°].—7. When warmed with *phenyl-urea* it reacts as follows: $NPhH.CO.NH_2 + Cl.CO.CO_2Et = NPhH.CO.NH.CO_2Et + CO + HCl$, and also in the following way: $NPhH.CO.NH_2 + Cl.CO.CO_2Et = NPh{<}{\begin{array}{c}CO\\ C_2O_2\end{array}}{>}NH + ClEt + H_2O$. The chief products are, therefore, **phenyl-allophanic ether**, which forms needles (from alcohol), [120°], and **phenyl-parabanic acid**, which forms plates (from alcohol), [208°].—8. With *di-phenyl-urea* it forms **di-phenyl-parabanic acid**, [204°]: $NPhH.CO.NPhH + Cl.CO.CO_2Et = NPh{<}{\begin{array}{c}CO\\ C_2O_2\end{array}}{>}NPh + EtCl + H_2O$.—9. With *tri-phenyl-guanidine* it forms **carbonyl-tri-phenyl-guanidine:**

$(NPhH)_2{:}C{:}NPh + 2Cl.CO.CO_2Et$

$= NPh{:}C{<}{\begin{array}{c}NPh\\ NPh\end{array}}{>}CO,HCl + HCl + CO + Et_2C_2O_4$.

The hydrochloride of this base forms concentric needles (from alcohol), [190°]; its nitrate, B',HNO_3, forms octahedra (from alcohol), [185°]. By means of fuming nitric acid white needles of the formula $C_{15}H_{12}N_2O_2,\frac{1}{2}aq$, may be got (M. v Stojentin, *J. pr.* [2] 32, 1).

CHLORO-GUANIDINE CH_4ClN_3. From guanidine carbonate and chlorine (Kamenski, *B.* 11, 1602). Pale yellow crystalline powder. Detonates about 147°.

CHLORO-HEPTANE *v.* HEPTYL CHLORIDE.

Di-chloro-heptane $C_7H_{14}Cl_2$ *i.e.* $Pr.CH_2.CH_2.CH_2.CHCl_2$. *Heptylidene chloride.* (191° cor.). From œnanthol and PCl_5 (Limpricht, *A.* 103, 80). Converted by Na into heptylene. Alcoholic KOH gives chloro-heptylene.

Di-chloro-heptane $C_7H_{14}Cl_2$ *i.e.* Pr_2CCl_2. (181°). From di-*n*-propyl ketone and PCl_5 (Tavildaroff, *B.* 9, 1442).

Di-chloro-heptane Pr_2CCl_2. From di-isopropyl ketone and PCl_5 (Henry, *B.* 8, 400). Splits up into HCl and $C_7H_{13}Cl$ on distillation. Alcoholic KOH gives C_7H_{12} (78°).

CHLORO-HEPTENOIC ACID $C_7H_{11}ClO_2$. From propyl-aceto-acetic ether and PCl_5 (Demarçay, *B.* 10, 1178). Oil.

Chloro-heptenoic acid $C_7H_{11}ClO_2$. From iso-propyl-aceto-acetic acid and PCl_5 (D.). Oil.

CHLORO-HEPTYL ALCOHOL $C_7H_{15}ClO$. (207°). S.G. $^{\underline{0}}$ 1·014. From octylene and HClO (De Clermont, *Z.* 1870, 411).

CHLORO-HEXANE *v.* HEXYL CHLORIDE.

Di-chloro-hexane $C_6H_{12}Cl_2$ *i.e.* $CH_3.CHCl.CH_2.CH_2.CHCl.CH_3$. (170°-180°). From diallyl and fuming HClAq (Wurtz, *A. Ch.* [4] 3, 161).

Di-chloro-hexane $C_6H_{12}Cl_2$. (c. 182°). S.G. $^{\underline{20}}$ 1·087. From the hexane of petroleum by chlorination (Cahours, *A. Ch.* [4] 1, 5).

Di-chloro-hexane $C_6H_{12}Cl_2$. (160°). Formed by chlorination of di-isopropyl (Schorlemmer, *A.* 144, 187; Silva, *B.* 6, 36; 7, 953).

Di-chloro-hexane $C_6H_{12}Cl_2$ *i.e.* $(CH_3)_2.CCl.CCl.(CH_3)_2$. [160°]. From pinacone and $POCl_3$ (Friedel a. Silva, *B.* 6, 35). Crystalline.

Di-chloro-hexane $(CH_3)_3C.CCl_2.CH_3$. [151°]. From pinacoline and PCl_5 (Favorsky, *J. pr.* [2] 37, 393). Very volatile crystals. Gives with alcoholic potash $CMe_3.C{:}CH$.

Di-chloro-hexane $C_6H_{12}Cl_2$ *i.e.* $CH_3.CHCl.CHCl.CH_2.CH_2.CH_3$. (c. 164°). S.G. $^{\underline{11}}$ 1·053. From chloro-ethyl-propyl-carbinol and PCl_5 (Henry, *Bl.* [2] 41, 363). Alcoholic KOH gives $C_6H_{11}Cl$ (122°).

Tri-chloro-hexane $C_6H_{11}Cl_3$. (c. 217°). S.G. $^{\underline{21}}$ 1·198. Formed by chlorinating *n*-hexane (Cahours, *J.* 1863, 525).

Hexa-chloro-hexane $C_6H_8Cl_6$. (c. 288°). S.G. ^{20} 1·598. From *n*-hexane and Cl (C.).

CHLORO-HEXENOIC ACID *v.* CHLORO-ETHYL CROTONIC ACID.

Chloro-hexenoic acid $C_6H_9ClO_2$. [64°]. From di-methyl-aceto-acetic ether and PCl_5 (D.).

CHLORO-HEXENYL ALCOHOL $C_6H_{11}ClO$. *Allyl-chloro-propyl carbinol* (c. 185°). S.G. $^{\underline{22}}$ 1·032. R_∞ 58·3. From epichlorhydrin (150 g.), allyl iodide (273 g.), and zinc at 0°; the product being treated with water (Lopatkin, *J. pr.* [2] 30, 390). Oil. Oxidation gives chloro-oxy-valeric acid.

Acetyl derivative $C_6H_{11}ClOAc$. (c. 205°). S.G. $^{\underline{0}}$ 1·065; $^{\underline{20}}$ 1·048. R_∞ 75·1.

Chloro-hexenyl alcohol $C_6H_{11}ClO$ *i.e.*

$CH_2{<}\begin{matrix}CH_2\\CHMe\end{matrix}{>}CCl.CH_2OH$ (?). *Chloro-methyl-tetra-methylene-carbinol.* (c. 167°). From the following di-chloro-hexenyl alcohol by treatment with iron and acetic acid (Natterer, *M.* 5, 579). Liquid, sl. sol. water. Does not combine with Br. Gives with PCl_5 a liquid $C_6H_9Cl_3$ (100° at 20 mm.).

Di-chloro-hexenyl alcohol $C_6H_{10}Cl_2O$ *i.e.*

$CH_2{<}\begin{matrix}CH_2\\CH(CH_2Cl)\end{matrix}{>}CCl.CH_2OH$ (?). (c. 117°) at 20 mm. From $\alpha\gamma$-di-chloro-crotonic aldehyde by successive treatment with $ZnEt_2$ and water (Natterer, *M.* 5, 567). Thick liquid; v. sl. sol. water. Does not combine with Br.

Acetyl derivative $C_6H_9Cl_2OAc$. (123°) at 20 mm. Converted by AgOAc at 110° into $C_6H_9Cl(OAc)_2$ (140° at 20 mm.).

CHLORO-HEXINENE *v.* HEXINYL CHLORIDE.

Tetra-chloro-hexinene $C_6H_6Cl_4$. Formed by the action of PCl_5 on mannite or dulcite (Bell, *B.* 12, 1273).

CHLORO-HEXOIC ACID $C_6H_{11}ClO_2$ *i.e.* $CEt_2Cl.CO_2H$. *Chloro-caproic acid.*

Ethyl ether EtA'. From PCl_5 and the oxy-acid (derived from oxalic ether) (Markownikoff, *B.* 6, 1175). On distillation it gives HCl and hexenoic ether; sodium amalgam gives hexoic (di-ethyl-acetic) acid.

γ-Chloro-isohexoic acid $Me_2CCl.CH_2.CH_2.CO_2H$.

Ethyl ether A'Et: (88° at 12 mm.). Formed by saturating an absolute alcoholic solution of isocaprolactone (the lactone of oxy-hexoic acid) with HCl. On distillation it evolves HCl and yields pyroterebic ether (Bredt, *B.* 19, 514).

Tri-chloro-hexoic acid $C_6H_9Cl_3O_2$. [64°]. Formed by oxidation of the corresponding aldehyde by HNO_3 (Pinner, *B.* 10, 1052). Zinc and HCl convert it into hexenoic acid.

TRI-CHLORO-HEXOIC ALDEHYDE $C_6H_9Cl_3O$. *Hexyl-chloral.* (213°). Occurs among the products of the chlorination of aldehyde (Pinner, *B.* 10, 1052). Potash splits it up into formic acid, $C_5H_4Cl_2$, and HCl.

CHLORO-HEXYL ALCOHOL $C_6H_{13}ClO$ *i.e.* $CH_3.CH_2.CH_2.CHCl.CH(OH).CH_3$. *Methyl chloro-butyl carbinol.* (170°). S.G. $^{\underline{11}}$ 1·018. From hexylene and HOCl (Domac, *M.* 2, 319). Iron and HOAc give *sec*-hexyl alcohol.

Chloro-hexyl alcohol $C_6H_{13}ClO$ *i.e.* $CH_3.CH_2.CH_2.CH(OH).CHCl.CH_3$ (?). *Hexylene chlorhydrin.* (171°). S.G. $^{\underline{11}}$ 1·014. From hexylene oxide and HCl (Henry, *C. R.* 97, 260). Oil, with sweetish taste.

Acetyl derivative $C_6H_{12}Cl.OAc$. (189°). S.G. $^{\underline{0}}$ 1·04.

δ-Chloro-*n*-hexyl-alcohol $CH_3.CHCl.CH_2.CH_2.CH_2.CH_2.OH$ (?). *Hexylene δ-chlorhydrin.* Formed by heating the glycol with HCl (Lipp, *B.* 18, 3283). Colourless liquid of peculiar smell. Heavier than water, in which it is insoluble. By further heating with HCl it is converted into the di-chloride.

Chloro-hexyl alcohol $C_6H_{13}ClO$ *i.e.* $CMe_2Cl.CMe_2.OH$. [55°]. From $CMe_2{:}CMe_2$ and HOCl (Eltekoff, *J. R.* 14, 390). Needles, smelling of camphor. Aqueous KOH forms pinacone; solid KOH gives hexylene oxide.

Di-chloro-hexyl alcohol $C_6H_{12}Cl_2O$. (208°). S.G. $^{\underline{12}}$ 1·4. From hexenyl alcohol and chlorine (Destrem, *A. Ch.* [5] 27, 58).

CHLORO-HEXYLENE *v.* HEXENYL CHLORIDE.

Di-chloro-hexylene $C_6H_{10}Cl_2$ *i. e.* $CH_3.CCl_2.CH_2.CH_2.CH{:}CH_2$. *Allyl-chloracetol.* (150°). From methyl butenyl ketone and PCl_5 (Henry, *C. R.* 87, 171). Heavy oil. Hot water reconverts it into the ketone. Alcoholic KOH gives C_6H_9Cl.

Di-chloro-hexylene. $C_6H_{10}Cl_2$. From mesityl oxide and PCl_5. Smells like turpentine and resinifies in the air. Distillation over lime converts it into C_6H_9Cl (130°) (Baeyer, *A.* 140, 298).

Penta-chloro-hexylene $C_6H_7Cl_5$. [102°]. From quercite by treatment with HCl. Needles (Prunier, *A. Ch.* [5] 15, 1).

***m*-CHLORO-HIPPURIC ACID** $C_9H_8ClNO_3$ *i.e.* [3:1] $C_6H_4Cl.CO.NH.CH_2.CO_2H$. From hippuric acid, $KClO_3$, and HCl (Otto, *A.* 122, 129). Found in the urine after taking *m*-chloro-benzoic acid (Græbe a. Schultzen, *A.* 142, 346). Viscid mass, sol. boiling water, mixes with alcohol and ether. Its alkaline solution turns brown in air. Boiling conc. HCl gives glycocoll and *m*-chloro-benzoic acid.

Salts.—$NaHA'_2 \frac{1}{2}aq$: stellate groups of needles.—CaA'_2: scales (from alcohol).—PbA'_2. [100°].

Di-chloro-hippuric acid $C_9H_7Cl_2NO_3$ *i.e.* [1:2:4] $C_6H_3Cl_2.CO.NH.CH_2.CO_2H$. Formed together with the preceding by chlorinating hippuric acid with HCl, and $KClO_3$ (O.). Soft, semi-crystalline mass; less sol. water than the preceding acid. Conc. HCl splits it up into glycocoll and (1, 2, 4)-di-chloro-benzoic acid.

Salts.—$NaA'aq$: soft warty crystals.—$CaA'_2 5aq$ (from hot water). — $CaA'_2 9aq$.—$CaA'_2 10aq$ (from cold water).—$BaA'_2 3aq$.—$PbA'_2 4aq$. — $(PbA'_2)_2PbO$.—AgA': cauliflower-like masses (from hot water).

Ethyl ether EtA'. Oil.

CHLORHYDRIN *v.* GLYCERIN.

Dichlorhydrin *v.* DI-CHLORO-PROPYL ALCOHOL and EPICHLORHYDRIN.

Trichlorhydrin *v.* TRI-CHLORO-PROPANE.

CHLORO-HYDRACRYLIC ACID *v.* CHLORO-OXY-PROPIONIC ACID.

CHLORO-HYDRO-ATROPIC ACID *v.* CHLORO-PHENYL-PROPIONIC ACID.

CHLORO-HYDRO-CINNAMIC ACID *v.* CHLORO-PHENYL-PROPIONIC ACID.

DI-CHLORO-HYDROCŒRULIGNON *v.* *Tetra-methyl*-DI-CHLORO-HEXA-OXY-DIPHENYL.

CHLORO-HYDRONAPHTHOQUINONE $C_{10}H_7ClO_2$ *i. e.* $C_{10}H_5Cl(OH)_2$ [117]. From chloro-(β)-naphthoquinone in acetic acid by passing in SO_2 (Zincke, *B.* 19, 2498). Needles (from water).

Di-chloro-hydronaphthoquinone $C_{10}H_6Cl_2O_2$ *i.e.* $C_{10}H_4Cl_2(OH)_2$. [125°]. From di-chloro-(β)-naphthoquinone and SO_2 (Zincke, *B.* 19, 2500). Slender needles.

Di-chloro-(α)-hydronaphthoquinone $C_{10}H_4Cl_2(OH)_2$. [135° uncor.]. Formed by shaking an ethereal solution of di-chloro-(α)-naphthoquinone with aqueous $SnCl_2$ till decolourised. Long colourless needles. V. sol. alcohol, ether, &c., insol. water. By air oxidation it is converted into the quinhydrone $C_{20}H_{10}Cl_4O_4$, which forms long violet-brown needles [250° uncor.] (Claus, *B.* 19, 1144; *cf.* Græbe, *A.* 149, 6).

Di-acetyl derivative $C_{10}H_4Cl_2(OAc)_2$. [236°].

CHLORO-HYDROQUINONE $C_6H_3Cl(OH)_2$. [106°]. (263°). Prepared by boiling quinone with HCl (Levy a. Schultz, *B.* 13, 1427; *A.* 210, 137; *cf.* Wöhler, *A.* 51, 155; Wichelhaus, *B.* 12, 1504). Also from chloro-quinone and SO_2 (Städeler, *A.* 69, 307). Monoclinic crystals, *a*:*b*:*c* = 2·77:1:2·31; β = 62° 3′. V. e. sol. water and alcohol, sl. sol. chloroform. On oxidation it gives chloroquinone. Heated with phthalic anhydride it produces a chlorinated quinizarine which is soluble in caustic soda with a blue colour. Combines with aniline with formation of $C_6H_3Cl(OH)_22NH_2Ph$ [92°] which crystallises from hot water in glittering plates (Niemeyer, *A.* 228, 322). With *p*-toluidine it forms a compound melting at 90°. These compounds are not decomposed by crystallising from hot benzene.

Di-acetyl derivative $C_6H_3Cl(OAc)_2$. [72°] (L. a. S); [99°] (Scheid, *A.* 218, 216). Transparent prisms. Sol alcohol.

Di-benzoyl derivative $C_6H_3Cl(OBz)_2$. [130°]. Long needles. Easily soluble in hot alcohol, sparingly in cold.

(*a*)-Di-chloro-hydroquinone $C_6H_2Cl_2(OH)_2$ [2:5:4:1]. [166°] (L. a. S.); [172°] (Krafft, *B.* 10, 800). Prepared by boiling chloro-quinone with HCl; or by passing dry HCl into a solution of chloroquinone in chloroform (Levy a. Schultz, *B.* 13, 1428; *A.* 210, 148). Formed also by reducing (*a*)-di-chloro-quinone [159°] with aqueous SO_2 (Städeler, *A.* 69, 312). Long needles (from boiling water). May be sublimed. On oxidation it gives (*a*)-dichloro-quinone. Combines with aniline forming $C_6H_2Cl_2(OH)_22NH_2Ph$ [113°], which crystallises in needles (from water), tables, or prisms (from benzene). The compound with *p*-toluidine melts at 115° (Niemeyer, *A.* 228, 328).

Di-acetyl derivative $C_6H_2Cl_2(OAc)_2$. [141°]. Formed by the action of acetyl chloride on quinone or chloro-quinone. Monoclinic crystals (Schulz, *B.* 15, 653; *A.* 210, 148) *a*:*b*:*c* = 2·9:1:1·13; β = 72° 40′.

Di-benzoyl derivative $C_6H_2Cl_2(OBz)_2$. [185°]. Woolly needles, sol. benzene, insol. water.

(β)-Di-chloro-hydro-quinone $C_6H_2Cl_2(OH)_2$ [2.6:4:1]. [158°]. Formed by reduction of the corresponding quinone [120°] (Faust, *A.* 149, 155). Yellowish laminæ (from dilute alcohol). Forms with *p*-toluidine a compound melting at 73°.

Di-acetyl derivative $C_6H_2Cl_2(OAc)_2$ [67°]; fine needles.

Di-benzoyl derivative $C_6H_2Cl_2(OBz)_2$ [105°]; colourless needles (Levy, *B.* 16, 1445).

Di-methyl ether $C_6H_2Cl_2(OMe)_2$. [126°]. Formed by chlorinating di-methyl-hydroquinone (Habermann, *B.* 11, 1034). Small needles; may be sublimed.

Di-isobutyl ether $C_6H_2Cl_2(OCH_2Pr)_2$ (Schubert, *M.* 3, 682).

Tri-chloro-hydroquinone $C_6HCl_3(OH)_2$. [134°]. Prepared, together with tetrachlorohydroquinone, by boiling (*a*)- or (β)-dichloroquinone with HCl, and separated from tetra-chloro-hydroquinone by solution in water (Levy a. Schultz, *B.* 13, 1429; *A.* 210, 153). Formed also by reducing tri-chloro-quinone with SO_2 (Städeler, *A.* 69, 321; Stenhouse, *A. Suppl.* 6, 214; Græbe, *A.* 146, 25), and by oxidising benzene with $KClO_3$ and H_2SO_4 (Krafft, *B.* 10, 797; Carius, *A.* 142, 129). Flattened prisms. Its alkaline solutions turn brown in the air, ultimately forming di-chloro-di-oxy-quinone (chloranilic acid). It forms two compounds with aniline: $C_6HCl_3(OH)_2$, NH_2Ph [60°], crystallising in small needles, and $C_6HCl_3(OH)_2$, $2NH_2Ph$ [67°], crystallising in trimetric tables. With phthalic anhydride it does not produce chlorinated quinizarine.

Di-acetyl derivative $C_6HCl_3(OAc)_2$. [153°]. Needles.

Di-benzoyl derivative $C_6HCl_3(OBz)_2$. [174°]. Needles.

Di-ethyl ether $C_6HCl_3(OEt)_2$. [68·5°]. Long needles.

Tetra-chloro-hydroquinone $C_6Cl_4(OH)_2$. [232°] (Sutkowski, *B.* 19, 2316).

Prepared by boiling (β)-dichloro-quinone or tri-chloro-quinone with HCl (Levy a. Schultz, *B.* 13, 1429; *A.* 210, 255), or by passing HCl into a solution of tri-chloro-quinone in acetic acid (Niemeyer, *A.* 228, 324). Formed also by boiling tetra-chloro-quinone with $SnCl_2$, with HClAq, with HBrAq, or with aqueous SO_2. Monoclinic pyramids; $a:b:c = 3{\cdot}0:1:2{\cdot}58$; $\beta = 76° 34'$. May be sublimed. Insol. water, v. sl. sol. benzene, v. sol. alcohol and ether. Reduces silver solution. PCl_5 converts it into C_6Cl_6. A conc. solution in hot potash deposits, on cooling, prisms of $C_6Cl_4(OK)_2$. A solution of this salt exposed to air forms $C_6Cl_2O_2(OK)_2$. Combines with aniline, forming $C_6Cl_4(OH)_2NH_2Ph$ [115°].

Di-acetyl derivative $C_6Cl_4(OAc)_2$. [245°].

Di-benzoyl derivative $C_6Cl_4(OBz)_2$. [233°]. Sol. benzene, sl. sol. alcohol.

Di-methyl ether $C_6Cl_4(OMe)_2$. [154°]. From di-methyl-hydroquinone and Cl (Habermann, *B.* 11, 1035). Needles.

Di-ethyl ether $C_6Cl_4(OEt)_2$. [112°]. From tetra-chloro-hydroquinone, KOH, EtI, and alcohol at 140° (Græbe, *A.* 146, 19). Needles.

Methyl ethyl ether $C_6Cl_4(OMe)(OEt)$. [101°]. From $C_6H_4(OMe)(OEt)$ and Cl (Fiala, *M.* 6, 912).

Di-isobutyl ether $C_6Cl_4(OCH_2Pr)_2$ (Schubert, *M.* 3, 682).

DI-*p*-CHLORO-HYDROQUINONE-DI-CARBOXYLIC ETHER *v.* DI-*p*-CHLORO-DI-*p*-OXY-TEREPHTHALIC ETHER.

DI-CHLORO-HYDROQUINONE DI-SULPHONIC ACID $C_6H_4Cl_2S_2O_8$ *i.e.* $C_6Cl_2(OH)_2(SO_3H)_2$. From tetra-chloro-quinone and aqueous $KHSO_3$ (Hesse, *A.* 114, 324; Greiff, *C. C.* 1863, 1044). The free acid is unstable. It gives an indigo-blue colour with Fe_2Cl_6. Alkaline solutions are oxidised by air to euthiochronic acid—K_2A'' 2aq.—$(NH_4)_2A''$ 2aq.

Tri-chloro-hydroquinone sulphonic acid $C_6H_3Cl_3SO_5$ *i.e.* $C_6Cl_3(OH)_2SO_3H$. Formed, together with euthiochronic acid, by dissolving tri-chloro-quinone in warm aqueous K_2SO_3 (Græbe, *A.* 146, 55). Deliquescent needles. Fe_2Cl_6 gives a blue colour.—KA'aq. Alkaline solutions are oxidised in air to

$$C_6Cl(OK)_2O_2(SO_3K).$$

CHLORO-HYDRO-THYMOQUINONE $C_{10}H_{13}ClO_2$ *i.e.* $C_6HCl(C_3H_7)(CH_3)(OH)_2$ [2:6:3:4:1]. [70°]. From thymoquinone and conc. aqueous HCl at 0° (Schniter, *B.* 20, 1317). Silky needles.

Di-acetyl derivative $C_{10}H_{11}Cl(OAc)_2$. [88°]. Formed by the action of acetyl chloride on thymoquinone. Large crystals.

Di-benzoyl derivative [118°]. Colourless needles (Schulz, *B.* 15, 657).

Di-chloro-hydrothymoquinone

Di-benzoyl derivative $C_{10}H_{10}Cl_2(OBz)_2$. [191°]. Formed by the action of benzoyl chloride on thymoquinone (Schulz, *B.* 15, 656). Sparingly soluble white needles.

CHLORO-HYDROTOLUQUINONE. $C_6H_2(CH_3)Cl(OH)_2$ [1:3or4:2:5]. [115° uncor.]. Formed by reduction of chloro-toluquinone [90°] with SO_2. Long colourless needles. Sublimable and volatile with steam (Claus a. Schweitzer, *B.* 19, 929).

Chloro-hydro-toluquinone $C_6H_2MeCl(OH)_2$. [175°]. Obtained by the action of cold conc. HCl upon toluquinone. White plates or needles. V. sol. alcohol, ether, and hot water, sl. sol. ligroin (Schniter, *B.* 20, 2283).

Di-chloro-hydro-toluquinone $C_6HMeCl_2(OH)_2$. [121°]. Formed by the action of HCl upon chloro-toluquinone. Not volatile with steam (Schniter, *B.* 20, 2288). Formed also by reducing di-chloro-toluquinone obtained from di-chlorinated *o*-cresol [54°] (Claus a. Schweitzer, *B.* 19, 937; *cf.* Southworth, *A.* 168, 274). Feathery crystals (from water). May be sublimed.

Di-chloro-hydrotoluquinone $C_6H(CH_3)Cl_2(OH)_2$. [171° uncor.]. Formed by reduction of di-chloro-toluquinone [103°] (from di-chloro-*m*-cresol) with SO_2. Colourless needles. V. e. sol. alcohol, ether, &c., sol. hot water, sl. sol. cold (Claus a. Schweitzer, *B.* 19, 931).

Acetyl derivative $C_6HMeCl_2(OAc)_2$. [124°] (Southworth).

Tri-chloro-hydrotoluquinone $C_6MeCl_3(OH)_2$. [212°]. From tri-chloro-toluquinone and aqueous SO_2 at 100° (Southworth; Borgmann, *A.* 152, 251; Hayduck, *A.* 172, 211; Claus a. Riemann, *B.* 16, 1603). Needles. Volatile with steam. Turns green in moist air.

Di-acetyl derivative $C_6MeCl_3(OAc)_2$. [114°].

Di-ethyl ether $C_6MeCl_3(OEt)_2$. [107°].

Tetra-chloro-hydrotoluquinone $C_7H_4Cl_4O_2$. From tetra-chloro-toluquinone and SO_2 (Bräuninger, *A.* 185, 353). Needles (by sublimation).

CHLORO-HYDROTOLUQUINONE DI-SULPHONIC ACID $C_6MeCl(OH)_2(SO_3H)_2$. From tri-chloro-toluquinone and conc. aqueous $KHSO_3$ (Borgmann, *A.* 152, 255).—KA': laminæ.

CHLORO-HYDROXYLOQUINONE $C_6HClMe_2(OH)_2$ [*x*:1:4:2:5]. [147°]. Formed, together with the di-chloro- compound, by treating xyloquinone (phlorone) with conc. HCl (Carstanjen, *J. pr.* [2] 23, 421). Needles. Fe_2Cl_6 colours its aqueous solution violet.

Di-chloro-hydroxyloquinone $C_6Cl_2Me_2(OH)_2$. [180°]. Formed as above (C.) or by reducing di-chloro-xyloquinone with aqueous SO_2 (Rad, *A.* 151, 164). Coloured violet by Fe_2Cl_6.

DI-CHLORO-ICOSYLENE $C_{20}H_{38}Cl_2$. S.G. ^{24} 1·013. From $C_{20}H_{38}$ and Cl (Lippmann a. Hawliczek, *B.* 12, 69).

CHLOROIMIDO-CARBONIC ACID $ClN{:}C(OH)_2$.

Methyl ether $ClN{:}C(OMe)_2$. [20°]. Formed by leading chlorine into a cooled solution of 80 pts. NaOH and 80 pts. KCN (96–98 p.c.) in 150 pts. of methyl alcohol. White crystalline solid. Its reactions are the same as those of the ethyl ether.

Ethyl ether $ClN{:}C(OEt)_2$. [39°]. Formed by leading chlorine into a cooled solution of 80 pts. NaOH and 80 pts. KCN in 200 pts. of ethyl alcohol; the yield is 50 pts. of the pure product. Large colourless prisms. V. sol. alcohol and ether, insol. water. Rotates on water. Decomposes on distillation. Heated with aqueous H_2S it yields carbonic ether NH_4Cl and S. By dilute acids it is split up into carbonic ether, chloride of nitrogen and NH_3. From HI it liberates iodine. By warming with a solution of potassium arsenite it is reduced to imido-carbonic ether $HN{:}C(OEt)_2$ (Sandmeyer, *B.* 19, 862).

TETRA-CHLORO-INDIGO $C_{16}H_6Cl_4N_2O_2$. Very analogous to ordinary indigo. Obtained by the ction of acetone and NaOH on di-chloro-nitro-benzoic aldehyde (Gnehm, *B.* 17, 752).

DI-CHLOR-INDOLE $C_8H_5Cl_2N$ *i.e.*

$C_6H_4<\begin{smallmatrix}CCl\\NH\end{smallmatrix}>CCl$. [104°]. *Chlor-oxindole-chloride.* From oxindole and PCl_5. Crystalline mass smelling like fæces. Colourless laminæ from hot water), v. e. sol. alcohol, ether, and benzene. Sol. alkalis. Can be methylated Baeyer, *B.* 12, 456; 15, 786).

DI-CHLORO-INDONAPHTHOQUINONE

$C_6H_4<\begin{smallmatrix}CO\\CO\end{smallmatrix}>CCl_2$. [125°].

Formation.—Tetrachloro-(β)-naphthoquinone is dissolved in Na_2CO_3Aq, HOAc is added and afterwards HCl and chromic acid, the mixture being gently warmed (Zincke, *B.* 21, 499).

Properties.—Plates (from dilute alcohol or HOAc).

DI-CHLORO-IODHYDRIN *v.* DI-CHLORO-IODO-PROPANE.

aβ- or *βa-***CHLORO-IODO-ACRYLIC ACID** $CHI:CCl.CO_2H$ or $CHCl:CI.CO_2H$. [72°]. Formed by boiling propiolic acid with an ethereal solution of ClI (Stolz, *B.* 19, 538). Pearly crystals. Easily soluble in all solvents.

Chloro-di-iodo-acrylic acid $C_3HO_2ClI_2$ *i.e.* $CI_2:CCl.CO_2H$(?). [143°]. Formed by boiling iodo-propiolic acid with an ethereal solution of ClI (Stolz, *B.* 19, 538). Colourless glistening plates. Sparingly soluble in ligroin and cold water, more easily in alcohol and ether.

o-**CHLORO-IODO-BENZENE** C_6H_4ClI [2:1]. (above 233°) (Korner); (230°) (B. a. K.). S.G. $\frac{24.5}{}$ 1·928. From *o*-chloro-aniline by displacing NH_2 by I through the diazo- reaction (Körner, *G.* 4, 343; Beilstein a. Kurbatoff, *A.* 176, 33).

p-**Chloro-iodo-benzene** C_6H_4ClI [4:1]. [56°]. (227°). From *p*-chloro-aniline by displacing NH_2 by I; or from *p*-iodo-aniline by displacing NH_2 by Cl.

CHLOR-IODO-BENZOIC ACID $C_6H_3ClI.CO_2H$ [210°]. Formed by the action of an alcoholic solution of iodine upon chloro-salicylic acid [172°] (Smith a. Knerr, *Am.* 8, 95). Curved needles. Sol. boiling water.

Salts.—BaA'_2. Arborescent crystals.

CHLORO-IODO-ETHANE C_2H_4ClI *i.e.* $CH_2Cl.CH_2I$. *Ethylene chloro-iodide.* (140°) (Thorpe, *C. J.* 37, 189). S.G. $\frac{0}{}$ 2·151 (Simpson); $\frac{0}{}$ 2·164 (Th.). Formed by the action of ICl on ethylene or ethylene iodide (Maxwell Simpson, *Pr.* 11, 590; *A.* 125, 101; 127, 372; *Suppl.* 6, 254).

Reactions.—1. Alcoholic KOH gives C_2H_3Cl. 2. Moist Ag_2O gives glycol. — 3. *Zinc* and H_2SO_4 gives ethylene.—4. *Silver* forms ethylene and ethylene chloride (Friedel a. Silva, *Bl.* [2] 17, 242).—5. Conc. HI forms, on heating, C_2H_4 and $C_2H_4I_2$.—6. *Ammonia* forms ethylene-diamine (Engel, *Bl.* [2] 48, 96).

Chloro-iodo-ethane $CH_3.CHICl$. *Ethylidene chloroiodide.* (118°). S.G. $\frac{12}{}$ 2·054.

Formation.—Iodine (26 g.) is suspended in water (120 g.) and saturated with chlorine in the cold. The chloride of iodine is then shaken with ethylidene iodide, the product washed with dilute KOH and distilled.

Preparation.—Al_2I_6 (8 g.) is dissolved in CS_2 (24 g.) and slowly added to ethylidene chloride (6 g.) dissolved in CS_2 (6 g.) and kept at 0° The product is treated as above (Maxwell Simpson, *Pr.* 27, 424).

Di-chloro-iodo-ethane $C_2H_3Cl_2I$. (172°). S.G. $\frac{0}{}$ 2·219. From C_2H_3Cl and ICl (Henry, *C. R.* 98, 518). Alcoholic KOH gives $CH_2:CCl_2$ (37°).

CHLORO-IODO-ETHYLENE C_2H_2ICl. *Acetylene chloro-iodide.* (119° i. V.) (Plimpton); (115°) (Sabanejeff). S.G. $\frac{0}{}$ 2·230 (P.); $\frac{0}{}$ 2·154 (S.); $\frac{19.5}{}$ 2·118 (S.). Formed by passing acetylene into a solution of ICl in HCl (Plimpton, *C. J.* 41, 392) or in ether (McGowan, *Pr. E.* 9, 589).

Preparation.—Chlorine is passed into water (6 pts.) containing iodine (1 pt.). The liquid is poured off from undissolved iodine, and acetylene is then passed in (Sabanejeff, *A.* 216, 264).

Reactions.—1. *Zinc* and alcohol gives off acetylene.—2. Alcoholic $AgNO_3$ forms needles of a double compound.—3. Heated with 50 vols. of *water* at 150°, it is dissolved in 6 days the products being HI, C_2HCl and chloro-ethylene oxide C_2H_3ClO (*q. v.*).—4. Alcoholic KOH gives off a gas that decomposes in air (chloro- or iodo-acetylene).

Chloro-iodo-ethylene $CH_2:CClI$. (101°). S.G. $\frac{0}{}$ 2·143. From chloro-bromo-iodo-ethane and alcoholic KOH (Henry, *C. R.* 98, 741). Oil; turns purple in air and light, absorbing oxygen

DI-CHLORO-TETRA-IODO-FLUORESCEIN. *Hydrate.* $C_{20}H_8Cl_2I_4O_6$. Formed by adding a solution of iodine in dilute KOH to an alkaline solution of di-chloro-fluorescein and acidifying (Le Royer, *A.* 238, 359). The alkaline salts are used as dyes ('Rose Bengale').

CHLORO-IODO-METHANE CH_2ICl. (109°). S.G. $\frac{22}{}$ 2·49. From $IHg.CH_2Cl$ and I_2 (Sakurai, *C. J.* 41, 362).

Di-chloro-iodo-methane $CHCl_2I$. (131°). S.G. $\frac{0}{}$ 2·454. *Chloriodoform.* A liquid formed by the action of $HgCl_2$ or PCl_5 on iodoform (Serullas, *A. Ch.* [2] 25, 314; 39, 225; Mitscherlich, *P.* 11, 164; Bouchardat, *A.* 22, 229; Schlagdenhauffen, *J. Ph.* [3] 30, 401; Borodin, *A.* 126, 239).

Di-chloro-di-iodo-methane CCl_2I_2. [85°]. From CHI_3 and $HgCl_2$ (Borodin, *A.* 126, 239). From CH_2Cl_2 and IBr (Höland, *A.* 240, 234). Glittering scales, with pungent odour. Turned brown by light, alcohol, and ether.

CHLORO-IODO-METHYL-PYRIDINE C_6H_5ClIN. [111°]. *Chloro-iodo-picoline.* From chloro-(α)-picoline, [21°], by digesting with I and NaOH. Prisms, apparently trimetric (Ost, *J. pr.* [2] 27, 257).

CHLORO-IODO-NITRO-BENZENE $C_6H_3ClI(NO_2)$ [1:3:4] [63°]. From the corresponding chloro-nitro-aniline [123°] by displacing NH_2 by I through the diazo- reaction (Körner, *G.* 4, 381). Prisms (from ether-alcohol); volatile with steam; sl. sol. cold alcohol.

Chloro-iodo-nitro-benzene $C_6H_3ClI(NO_2)$ [1:4:3]. [63°]. From chloro-nitro-aniline [116°] by the diazo- reaction (K.). Spherical groups of needles (from hot alcohol).

CHLORO-IODO-*o*-OXY-BENZOIC ACID $C_6H_2(OH)ClI(CO_2H)$ [2:*x*:5:1]. *Chlor-iodo-salicylic acid.* [224°]. Prepared by heating chloro-salicylic acid with iodine and HgO in alcoholic solution (Smith a. Knerr, *Am.* 8, 95). Colourless needles (from dilute alcohol). V. sl. sol. hot water. Gives a violet colour with Fe_2Cl_6.

Salts.- $BaA'_2 4\frac{1}{2}aq$: pink needles; m. sol. water. — $NaA' 2aq$: flat needles. — $CaA'_2 5aq$: pink needles; sol. water.—$MgA'_2 5\frac{1}{2}aq$: pink leaflets; sol. hot water. — $ZnA'_2 3aq$: white needles; v. sol. hot water.

Methyl ether MeA′. [130°]. Flat needles.

Ethyl ether EtA′. White plates. V. sol. hot alcohol.

TRI-CHLORO-IODO-PHENOL $C_6HCl_3I(OH)$. [80°]. From tri-chloro-amido-phenol by diazo-reaction (Lampert, *J. pr.* [2] 33, 391). White needles (from alcohol).

Ethyl derivative $C_6HCl_3I(OEt)$. [61°].

CHLORO-IODO-PROPANE C_3H_6ClI *i.e.* $CH_3.CHCl.CH_2I$. (149°). S.G. ^{0} 1·933; ^{25} 1·889. From propylene and aqueous ICl (Maxwell Simpson, *Pr.* 12, 278; Friedel a. Silva, *A. Ch.* [2] 17, 535). Converted by $HgCl_2$ at 100° into propylene chloride. HI at 100° gives isopropyl iodide and isopropyl chloride (Sorokin, *B.* 3, 626; Silva, *C. R.* 93, 739). Alcoholic KOH gives $CH_3.CCl:CH_2$.

Chloro-iodo-propane $CH_3.CClI.CH_3$. *Chloro-iodo-acetol.* (c. 120°) at 10 mm. S.G. ^{0} 1·821. From $CH_3.CCl:CH_2$ and HI (Oppenheim, *A. Suppl.* 6, 359). Decomposed by distillation under atmospheric pressure. Moist Ag_2O gives acetone.

Di-chloro-iodo-propane $C_3H_5Cl_2I$. *Di-chloro-iodhydrin.* (c. 208°). From $C_3H_5ClI(OH)$ and PCl_5 (Henry, *B.* 4, 701).

CHLORO-IODO-PROPYL ALCOHOL $C_3H_5ClI(OH)$. *Glycerin chloroiodhydrin.* (226°). S.G. ^{12} 2·06. From epiiodhydrin and HCl; or from epichlorhydrin and HI (Reboul, *A. Suppl.* 1, 225). Conc. KOHAq gives epichlorhydrin.

CHLORO-IODO-PROPYLAMINE $C_3H_5ClI(NH_2)$. From allylamine hydrochloride and ICl (Henry, *B.* 8, 399).—$B'_2H_2PtCl_6$.

CHLORO-IODO-PROPYLENE C_3H_4ClI *i.e.* $CH_2:CCl.CH_2I$. (c. 150°). S.G. ^{15} 1·913. From di-chloro-propylene and CaI_2 at 100° (v. Romburgh, *R. T. C.* 1, 233). Combines with mercury. Heated with KOH or Ag_2O it yields *a*-chloro-allyl alcohol. $AgNO_3$ gives *a*-chloro-allyl nitrate.

Chloro-iodo-propylene C_3H_4ClI *i.e.* $CHCl:CH.CH_2I$. (162°). S.G. ^{12} 1·97. Colourless liquid, with irritating odour and sharp taste. Prepared by heating dry CaI_2 with $CHCl:CH.CH_2Cl$ at 100°, or by heating dry KI or CaI_2 in excess with allylidene chloride at 100° for 24 hours. Combines with Hg forming white plates, very soluble in alcohol. With KOH it yields *β*-chloro-allyl alcohol (P. v. Romburgh, *R. T. C.* 1, 233).

(*a*)-**CHLORO-IODO-TOLUENE** C_7H_6ClI. (243°). S.G. ^{17} 1·716. From (*a*)-chloro-nitro-toluene by reduction and displacement of NH_2 by I through the diazo- reaction (Wroblewsky, *Z.* [2] 6, 164; *A.* 168, 210). Liquid.

(*β*)-**Chloro-iodo-toluene** C_7H_6ClI. [10°]. (240°). S.G. $^{19·5}$ 1·770. From (*β*)-chloro-nitro-toluene (W.).

Chloro-iodo-toluene C_7H_6ClI. (240°). S.G. ^{49} 1·702. From chlorinated *o*-toluidine (Beilstein a. Kuhlberg, *A.* 156, 82).

CHLORO-ISATIN *v.* ISATIN.

CHLORO-ISATOIC ACID $C_8H_4ClNO_3$ *i.e.*

$C_6H_3Cl{<}\substack{CO\\N}{>}CO_2H$. [265°-268°]. From chloro-isatin (10 g.), CrO_3 (20 g.), and HOAc (120 g.) (Dorsch, *J. pr.* [2] 33, 49). Pearly plates (from alcohol-acetone). Insol. water, ether, and benzene. Boiling conc. HCl gives CO_2 and chloro-*o*-amido-benzoic acid. Ammonia gives CO_2 and chloro-benzamide.

Di-chloro-isatoic acid

$C_6H_2Cl_2{<}\substack{CO\\N}{>}CO_2H$. [256°]. From di-chloro-isatin (10 g.), CrO_3 (15 g.), and HOAc (60 g.) (D.). Yellow prisms (from alcohol-acetone).

CHLORO-LACTIC ACID *v.* CHLORO-OXY-PROPIONIC ACID.

CHLORO-LEVULIC ACID *v.* CHLORO-ACETYL-PROPIONIC ACID.

CHLORO-LUTIDINE *v.* CHLORO-DI-METHYL-PYRIDINE.

CHLORO-MALEÏC ACID $C_2ClH(CO_2H)_2$. [172°]. The acid so called by Perkin and Duppa is probably chloro-fumaric acid (*q. v.*).

Formation.—Among the products of the action of ClOH on benzene (Carius, *A.* 142, 139; 155, 217; *cf.* Kekulé a. Strecker, *A.* 223, 183).

Salts.—KHA″ aq.—BaA″ 5aq. Crusts.

Anhydride $C_2ClH:C_2O_3$. [0°] and [34·5°]. Formed by heating a mixture of chloro-fumaric acid and its chloride (Perkin, *C. J. Proc.* 4, 76). Dimorphous.

Di-chloro-maleïc acid $C_2Cl_2(CO_2H)_2$.

Preparation.—The chloride $C_2Cl_2(C_2Cl_4O)$ (see below) warmed with conc. H_2SO_4 dissolves with evolution of HCl. The crystals which separate (anhydride) are dissolved in water (becoming hydrated), the solution is extracted with ether, and the ethereal extract evaporated and placed over H_2SO_4. Hygroscopic crystals of the acid are formed. On sublimation they split up into H_2O and the anhydride, $C_2Cl_2(CO)_2O$. The acid may also be obtained by boiling its imide with potash.

Properties.—Hygroscopic crystals. Changes over H_2SO_4 into the anhydride. Also by boiling with ligroin (40°), in which the anhydride dissolves, but the acid does not.

Salt.—Ag_2A''. Silky needles. Explodes when heated.

Methyl ether.—Me_2A''. (225°).

Anhydride $C_2Cl_2(CO)_2O$. [120°]. Laminæ; may be sublimed. Slowly dissolves in water, changing to the acid.

Tetrachlorinated derivative of the anhydride $C_2Cl_2(C_2Cl_4O)$.

(*β*) Solid: [41°] (209°). V.D. (H=1) 254 (Theory 277). (? $C_2Cl_2(CCl_2)_2O$).

(*a*) Liquid: (194°-214°). V.D. (H=1) 236 (? $C_2Cl_2(CCl_3)COCl$).

Preparation.—By heating a mixture of $POCl_3$ (24 g.), succinyl chloride (8 g.) and PCl_5 (45 g.) in sealed tubes at 230°. The product is distilled and the fraction 125°-215° is treated with water. The heavy oil which separates is distilled with steam. It is chiefly liquid chloride. To get the solid isomeride, the liquid is heated with PCl_5 at 250°, the product poured into water and distilled with steam. The oily distillate is dried over $CaCl_2$ and distilled. The distillate deposits plates of the solid chloride, which may be recrystallised from alcohol of 90 per cent. (Kauder, *J. pr.* [2] 31, 2, 7).

Reactions.—1. Warm conc. H_2SO_4 converts both the solid and the liquid chloride into di-chloro-maleïc anhydride.—2. The vapour undergoes dissociation when heated strongly, hence the V.D. is rather low.—3. Water and dilute NaOH have hardly any action on the chlorides. The liquid chloride is readily decomposed by alcoholic NaOH, forming di-chloro-maleïc acid.—4. Sodium amalgam reduces it in alcoholic solution to succinic acid, di-chloro-maleïc anhydride being also formed.—5. The liquid chloride is violently attacked by ammonia. The solid chloride is not attacked by alcoholic ammonia below 130°. Ethylamine and aniline attack the liquid, but not the solid chloride.—6. Neither chloride is attacked by Cl or Br.—7. PCl_5 at 250° converts the liquid into the solid chloride, but breaks both up thus:

$$C_2Cl_2(C_2Cl_4O) + 3PCl_5 = 2C_2Cl_6 + 2PCl_3 + PCl_3O.$$

Imide $C_4Cl_2O_2NH$. Formed by chlorination of succinimide at 150°, or by boiling per-chloro-pyrocoll ortho-bromide with dilute acetic acid (Ciamician a. Silber, *B.* 16, 2393; 17, 553; *G.* 14, 31). Trimetric crystals, *a*:*b*:*c* = ·9922 : 1 : 1·5934. V. sol. hot water, alcohol, and ether. Heated with PCl_5 at 200° for 24 hours it is converted into the per-chloride C_4Cl_7N, which is reduced by zinc-dust and HCl to tetra-chloro-pyrrol. By heating with water it yields (*a*)-di-chloro-acrylic acid, CO_2, and NH_3.

Perchlorinated imide C_4Cl_7N. [70°–73°]. (144° at 20 mm.). White wax-like solid. V. sol. alcohol, ether, and acetic acid, nearly insol. water. Formed by heating di-chloro-maleimide with PCl_5 at 200° for 24 hours. Zinc-dust and acetic or hydrochloric acid reduce it to tetra-chloro-pyrrol (Ciamician a. Silber, *B.* 17, 554).

Phenyl-imide $C_2Cl_2<\substack{CO\\CO}>NPh$. [201°]. Silvery plates. Got by action of PCl_5 on phenyl-succinimide (*v.* SUCCINIMIDE). HCl decomposes it into aniline and di-chloro-maleïc acid.

CHLOROMALONIC ACID $C_3H_3ClO_4$ *i.e.* $CHCl:(CO_2H)_2$. [133°]. Formed by saponification of the ether by cold alcoholic KOH (Conrad a. Guthzeit, *B.* 15, 605). Prisms. Sol. water, alcohol, and ether. Heated to 180° it loses CO_2 and gives chloro-acetic acid.—A′Ag: white crystalline pp.

Diethyl ether $A''Et_2$. (222°). S.G. $\frac{20}{15}$ 1·185. Prepared by the action of chlorine on malonic ether. On saponification with KOH it gives tartronic acid (Conrad a. Bischoff, *B.* 13, 600; *A.* 209, 218). The sodium derivative reacts with [2:1] $C_6H_4(CH_2Br)_2$ with production of $C_6H_4(CH_2.CCl(CO_2Et)_2)_2$, whence alcoholic KOH gives $C_6H_4(CH:CH.CO_2H)_2$ (Perkin, *C. J.* 53, 14).

Amide $CHCl(CONH_2)_2$. [170°]. Tables, v. sol. hot water and alcohol.

CHLORO-MECONIC ACID *v.* MECONIC ACID.

CHLORO-MECYLENE *v.* CHLORO-PENTINENE.

CHLORO-TRIMESIC ACID $C_6H_2Cl(CO_2H)_3$. [278°]. From oxy-trimesic acid and PCl_5 (Ost, *J. pr.* [2] 15, 308). Needles or tables (from water) (containing aq).—$Ba_3A'''_2$ 7aq: m. sol. hot water.

CHLORO - MESITYLENE $C_6H_2Cl(CH_3)_3$. (205°). Formed, together with di- and tri-chloro-mesitylene by passing chlorine into cold mesitylene (Fittig a. Hoogewerff, *A.* 150, 323; *Z.* [2] 5, 168). Fuming HNO_3 forms a di-nitro-derivative [177°].

ω-Chloro-mesitylene $C_6H_3(CH_3)_2CH_2Cl$. (215°–220°). Obtained by chlorinating mesitylene at 215° (Robinet, *C. R.* 96, 500). NaOAc gives $C_6H_3(CH_3)_2CH_2OAc$. (242°).

Di-chloro-mesitylene $C_6HCl_2(CH_3)_3$. [59°]. (244°). Formed by chlorinating cold mesitylene (F. a. H.). Prisms (from alcohol). Volatile with steam.

ω-Di-chloro-mesitylene $C_6H_3(CH_3)(CH_2Cl)_2$. [41°]. (260°). Formed by chlorinating mesitylene at 215° (R.). Needles.

Tri-chloro-mesitylene $C_6Cl_3(CH_3)_3$. [205°] (F. a. H.); [208°] (Kurbatoff, *J. R.* 1883 [1] 129). (280°). From cold mesitylene and excess of Cl (Kane, *P.* 44, 474; F. a. H.). From *o*-di-chloro-benzene, Al_2Cl_6, and MeCl at 100° (Friedel a. Crafts, *A. Ch.* [6] 10, 411). Slender needles (from alcohol). Not attacked by oxidising agents. HI (S.G. 1·9) heated with it forms mesitylene.

ω-Tri-chloro-mesitylene $C_6H_3(CH_2Cl)_3$. (c. 280°). Prepared by heating the corresponding alcohol with HCl and fractionating the crude product *in vacuo*. Has not been obtained pure. Heavy oil. Boiled with water and $PbCO_3$ it re-generates $C_6H_3(CH_2OH)_3$ (Colson, *A. Ch.* [6] 6, 97).

CHLORO-MESITYLENIC ACID $C_6H_2Cl(CH_3)_2(CO_2H)$ [4:3:5:1]. From chloro-mesitylene and dilute HNO_3 (Fittig a. Hoogewerff, *A.* 150, 325). Monoclinic prisms (from alcohol). Turns brown above 200° without melting. Sl. sol. boiling water.—BaA'_2 4aq.—CaA'_2 5aq: tufts of flattened needles.

CHLORO-METHACRYLIC ACID $C_4H_5ClO_2$. [59°]. From tri-chloro-isobutyric acid, HCl, and zinc-dust (Gottlieb, *J. pr.* [2] 12, 19). Formed also by heating an aqueous solution of sodium citra-di-chloro-pyrotartrate; or by passing chlorine into an aqueous solution of sodium citraconate (Swarts, *J.* 1873, 583; Morawski, *J. pr.* [2] 12, 369; *Sitz. W.* [2] 74, 39). Needles, volatile with steam.

Salts.—KA′ aq.—AgA′.—CaA'_2 3aq.—BaA'_2 4aq.—PbA'_2 aq.—CuA′(OH).

Ethyl ether EtA′. (157°).

Di-chloro-methacrylic acid $C_4H_4Cl_2O_2$. [64°]. (216°). Formed by the action of alkalis on tri-chloro-isobutyric acid (Gottlieb, *J. pr.* [2] 12, 8; Morawski, *C. C.* 1877, 131). Slender prisms; may be sublimed. Attacks the skin. Sodium amalgam forms isobutyric acid.—NaA′ aq.—KA′ $\frac{1}{2}$aq.—AgA′.—CaA'_2 2aq.—PbA'_2 aq. [100°].—CuA'_2.

CHLORO-METHANE *v.* METHYL CHLORIDE.

Di-chloro-methane *v.* METHYLENE CHLORIDE.

Tri-chloro-methane *v.* CHLOROFORM.

Tetra-chloro-methane *v.* CARBON-TETRA-CHLORIDE, vol. i. p. 688.

CHLORO - METHANE - TRICARBOXYLIC ETHER $CCl(CO_2Et)_3$ (210°) at 140 mm. Prepared by chlorination of methane-tricarboxylic ether. By saponification it yields oxy-methane-tricarboxylic acid (carboxytartronic acid) (Conrad, *B.* 14, 618).

TRI-CHLORO-METHANE SULPHINIC ACID $CCl_3.SO_2H$. From tri-chloro-methane sulpho-chloride and alcoholic KCN or H_2S (Lōw, *Z.* 1869, 82, 614; Rathke, *A.* 161, 149). Unstable needles.—**Salts.**—KA′. Its solution gives with Br a characteristic pp. of $CCl_3.SO_2Br$. Boiling water converts it into $CHCl_2(SO_2K)$. HNO_3 gives less needles (from dilute alcohol). V. sl. sol. hot water. Gives a violet colour with Fe_2Cl_6.

Salts.—$BaA'_2 4\frac{1}{2}aq$: pink needles; m. sol. water.—$NaA' 2aq$: flat needles.—$CaA'_2 5aq$: pink needles; sol. water.—$MgA'_2 5\frac{1}{2}aq$: pink leaflets; sol. hot water.—$ZnA'_2 3aq$: white needles; v. sol. hot water.

Methyl ether MeA'. [130°]. Flat needles.

Ethyl ether EtA'. White plates. V. sol. hot alcohol.

TRI-CHLORO-IODO-PHENOL $C_6HCl_3I(OH)$. [80°]. From tri-chloro-amido-phenol by diazo-reaction (Lampert, *J. pr.* [2] 33, 391). White needles (from alcohol).

Ethyl derivative $C_6HCl_3I(OEt)$. [61°].

CHLORO-IODO-PROPANE C_3H_6ClI *i.e.* $CH_3.CHCl.CH_2I$. (149°). S.G. ^{0} 1·933; ^{25} 1·889. From propylene and aqueous ICl (Maxwell Simpson, *Pr.* 12, 278; Friedel a. Silva, *A. Ch.* [2] 17, 535). Converted by $HgCl_2$ at 100° into propylene chloride. HI at 100° gives isopropyl iodide and isopropyl chloride (Sorokin, *B.* 3, 626; Silva, *C. R.* 93, 739). Alcoholic KOH gives $CH_3.CCl:CH_2$.

Chloro-iodo-propane $CH_3.CClI.CH_3$. *Chloro-iodo-acetol.* (c. 120°) at 10 mm. S.G. ^{0} 1·821. From $CH_3.CCl:CH_2$ and HI (Oppenheim, *A. Suppl.* 6, 359). Decomposed by distillation under atmospheric pressure. Moist Ag_2O gives acetone.

Di-chloro-iodo-propane $C_3H_5Cl_2I$. *Di-chloro-iodhydrin.* (c. 208°). From $C_3H_5ClI(OH)$ and PCl_5 (Henry, *B.* 4, 701).

CHLORO-IODO-PROPYL ALCOHOL $C_3H_5ClI(OH)$. *Glycerin chloroiodhydrin.* (226°). S.G. ^{12} 2·06. From epiiodhydrin and HCl; or from epichlorhydrin and HI (Reboul, *A. Suppl.* 1, 225). Conc. KOHAq gives epichlorhydrin.

CHLORO-IODO-PROPYLAMINE $C_3H_5ClI(NH_2)$. From allylamine hydrochloride and ICl (Henry, *B.* 8, 399).—$B'_2H_2PtCl_6$.

CHLORO-IODO-PROPYLENE C_3H_4ClI *i.e.* $CH_2:CCl.CH_2I$. (c. 150°). S.G. ^{15} 1·913. From di-chloro-propylene and CaI_2 at 100° (v. Romburgh, *R. T. C.* 1, 233). Combines with mercury. Heated with KOH or Ag_2O it yields α-chloro-allyl alcohol. $AgNO_3$ gives α-chloro-allyl nitrate.

Chloro-iodo-propylene C_3H_4ClI *i.e.* $CHCl:CH.CH_2I$. (162°). S.G. ^{12} 1·97. Colourless liquid, with irritating odour and sharp taste. Prepared by heating dry CaI_2 with $CHCl:CH.CH_2Cl$ at 100°, or by heating dry KI or CaI_2 in excess with allylidene chloride at 100° for 24 hours. Combines with Hg forming white plates, very soluble in alcohol. With KOH it yields β-chloro-allyl alcohol (P. v. Romburgh, *R. T. C.* 1, 233).

(α)-**CHLORO-IODO-TOLUENE** C_7H_6ClI. (243°). S.G. ^{17} 1·716. From (α)-chloro-nitro-toluene by reduction and displacement of NH_2 by I through the diazo- reaction (Wroblewsky, *Z.* [2] 6, 164; *A.* 168, 210). Liquid.

(β)-**Chloro-iodo-toluene** C_7H_6ClI. [10°]. (240°). S.G. $^{19·5}$ 1·770. From (β)-chloro-nitro-toluene (W.).

Chloro-iodo-toluene C_7H_6ClI. (240°). S.G. ^{49} 1·702. From chlorinated *o*-toluidine (Beilstein a. Kuhlberg, *A.* 156, 82).

CHLORO-ISATIN *v.* ISATIN.

CHLORO-ISATOIC ACID $C_8H_4ClNO_3$ *i.e.* $C_6H_3Cl\langle\substack{CO\\N}\rangle CO_2H$. [265°–268°]. From chloro-isatin (10 g.), CrO_3 (20 g.), and HOAc (120 g.) (Dorsch, *J. pr.* [2] 33, 49). Pearly plates (from alcohol-acetone). Insol. water, ether, and benzene. Boiling conc. HCl gives CO_2 and chloro-*o*-amido-benzoic acid. Ammonia gives CO_2 and chloro-benzamide.

Di-chloro-isatoic acid $C_6H_2Cl_2\langle\substack{CO\\N}\rangle CO_2H$. [256°]. From di-chloro-isatin (10 g.), CrO_3 (15 g.), and HOAc (60 g.) (D.). Yellow prisms (from alcohol-acetone).

CHLORO-LACTIC ACID *v.* CHLORO-OXY-PROPIONIC ACID.

CHLORO-LEVULIC ACID *v.* CHLORO-ACETYL-PROPIONIC ACID.

CHLORO-LUTIDINE *v.* CHLORO-DI-METHYL-PYRIDINE.

CHLORO-MALEÏC ACID $C_2ClH(CO_2H)_2$. [172°]. The acid so called by Perkin and Duppa is probably chloro-fumaric acid (*q. v.*).

Formation.—Among the products of the action of ClOH on benzene (Carius, *A.* 142, 139; 155, 217; *cf.* Kekulé a. Strecker, *A.* 223, 183).

Salts.—KHA'' aq.—BaA'' 5aq. Crusts.

Anhydride $C_2ClH:C_2O_3$. [0°] and [34·5°]. Formed by heating a mixture of chloro-fumaric acid and its chloride (Perkin, *C. J. Proc.* 4, 76). Dimorphous.

Di-chloro-maleïc acid $C_2Cl_2(CO_2H)_2$.

Preparation.—The chloride $C_2Cl_2(C_2Cl_4O)$ (see below) warmed with conc. H_2SO_4 dissolves with evolution of HCl. The crystals which separate (anhydride) are dissolved in water (becoming hydrated), the solution is extracted with ether, and the ethereal extract evaporated and placed over H_2SO_4. Hygroscopic crystals of the acid are formed. On sublimation they split up into H_2O and the anhydride, $C_2Cl_2(CO)_2O$. The acid may also be obtained by boiling its imide with potash.

Properties.—Hygroscopic crystals. Changes over H_2SO_4 into the anhydride. Also by boiling with ligroin (40°), in which the anhydride dissolves, but the acid does not.

Salt.—Ag_2A''. Silky needles. Explodes when heated.

Methyl ether.—Me_2A''. (225°).

Anhydride $C_2Cl_2(CO)_2O$. [120°]. Laminæ; may be sublimed. Slowly dissolves in water, changing to the acid.

Tetrachlorinated derivative of the anhydride $C_2Cl_2(C_2Cl_4O)$.

(β) Solid: [41°] (209°). V.D. (H=1) 254 (Theory 277). (? $C_2Cl_2(CCl_2)_2O$).

(α) Liquid: (194°–214°). V.D. (H=1) 236 (? $C_2Cl_2(CCl_3)COCl$).

Preparation.—By heating a mixture of $POCl_3$ (24 g.), succinyl chloride (8 g.) and PCl_5 (45 g.) in sealed tubes at 230°. The product is distilled and the fraction 125°–215° is treated with water. The heavy oil which separates is distilled with steam. It is chiefly liquid chloride. To get the solid isomeride, the liquid is heated with PCl_5 at 250°, the product poured into water and distilled with steam. The oily distillate is dried over $CaCl_2$ and distilled. The distillate deposits plates of the solid chloride, which may be recrystallised from alcohol of 90 per cent. (Kauder, *J. pr.* [2] 31, 2, 7).

Reactions.—1. Warm conc. H_2SO_4 converts both the solid and the liquid chloride into di-

118°]: needles, sol. alcohol, HOAc, and ether. . On heating with *alkalis* chloroform is split ff, and methyl-amido-benzoic aldehyde is ormed.

Salt.—B'HCl: thick prisms, v. sol. hot, v. l. sol. cold, water.

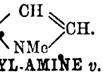
Tri-chloro-di-methyl-*p*-amido-phenyl ethyl lcohol $CCl_3.CH(OH).C_6H_4.NMe_2$. [111°]. White lates. Obtained by adding 5 pts. of powdered nCl_2 to a cooled mixture of 10 pts. of chloral ydrate and 40 pts. of dimethylaniline, and alowing the mixture to stand at about 50° for 24 ours; yield 7 pts. By boiling with aqueous or lcoholic KOH it is decomposed into chloroform nd di-methyl-*p*-amido-benzaldehyde [73°].—'HCl. Sparingly soluble colourless needles œssneck, *B.* 18, 1516).

***p*-CHLORO-TETRA-METHYL-*p*-DI-AMIDO-RI-PHENYL-METHANE** $_6H_4Cl.CH(C_6H_4.NMe_2)_2$. [143°]. Obtained by eating together di-methyl-aniline and *p*-chloro-nzaldehyde in presence of $ZnCl_2$ (Kaeswurm, . 19, 742). Small colourless concentric needles. ol. benzene, alcohol and ether, sparingly in groin, insol. water. On oxidation it gives the rbinol base which forms colourless crystals 46°], easily sol. benzene and ether, of which the inc double chloride is a bluish-green dyestuff.

Salts.—$B''H_2Cl_2PtCl_4$: easily sol. yellow rystalline pp. The chloride and sulphate re easily soluble colourless salts.

Exo-**Di-chloro-di-methyl-di-amido-di-phenyl-ethane** $CCl_2(C_6H_4NMe_2)_2$. From $CS(C_6H_4NMe_2)_2$ nd BzCl in CS_2 (Baither, *B.* 20, 3289). Conerted by water into the ketone $CO(C_6H_4NMe_2)_2$.

ω-CHLORO-METHYL-*o*-AMIDO-STYRENE $_6H_4(NHMe).CH:CHCl$. Formed by methylation f chloro-amido-styrene (Lipp, *B.* 17, 2509). iquid. V. sol. alcohol and ether, nearly insol. ater. Volatile with steam. Heated with odium ethylate at 130°–140° it is converted nto methyl-indole



$C_6H_4\left<\begin{matrix}CH\\NMe\end{matrix}\right>CH$.

ν-DI-CHLORO-METHYL-AMINE *v.* METHYL-MINE.

CHLORO-METHYL-ANILINE C_7H_8ClN *i.e.* $_6H_4Cl.NHMe$. (240°). Formed by treating $Me(CHO).C_6H_3Cl.CO_2H$ with conc. HCl (La oste a. Bodewig, *B.* 18, 430). Liquid.—'HCl: [164°].

***m*-Chloro-methyl-aniline** [3:1] $C_6H_4Cl.NHMe$. *cetyl derivative* $C_6H_4Cl.NMeAc$. [93°]. rom *m*-chloro-di-methyl aniline and AcBr Staedel, *B.* 19, 1948). Tables, v. e. sol. benzene.

***p*-Chloro-methyl-aniline** *Nitrosamine.* $_6H_4Cl.NMe.NO$. [51°]. From *p*-chloro-di-ethyl-aniline and nitrous acid (Koch, *B.* 20, 459).

***o*-Chloro-di-methyl-aniline** $C_6H_4Cl(NMe_2)$[1:2]. 206°). Formed by heating *o*-chloraniline ydrobromide (1 mol.) with methyl alcohol rather more than 2 mols.) for 10 hours at 145°. olourless fluid. The hydrochloride forms ygroscopic needles, the ferrocyanide white rystals, insol. water.—$B'_2H_2Cl_2PtCl_4$ (Heidlberg, B. 20, 149).

***m*-Chloro-di-methyl-aniline** [3:1] $C_6H_4Cl.NMe_2$. 232°). From *m*-chloro-aniline hydrobromide (a ittle over 2 mols.) and MeOH (1 mol.) by heatng for 8 hours at 145° (Baur a. Staedel, *B.* 16, 32). AcBr decomposes it in the cold, displacing Me by Ac, and forming $C_6H_4ClNMeAc$ (Staedel, *B.* 19, 1948).—B'HBr: red plates.—B'HCl: slender needles.—$B'_2H_2PtCl_6$: slender yellow needles.

***p*-Chloro-di-methyl-aniline** $C_6H_4Cl.NMe_2$[1:4]. [36°]. (230°). Prepared by the action of Cu_2Cl_2 upon the diazo- compound of *u*-di-methyl-*p*-phenylene diamine. Large flat glistening needles. Sol. alcohol, ether, and benzene, insol. water. The ferrocyanide forms microscopic prisms.—$B'_2H_2Cl_2PtCl_4$: golden-yellow prisms (Heidlberg, *B.* 20, 151).

Di-chloro-di-methyl-aniline $C_6H_3Cl_2NMe_2$. (234°). From dimethylaniline and Cl or SO_2Cl_2 (Krell, *B.* 5, 878; Wenghöffer, *J. pr.* [2] 16, 462). Liquid.—$B'_2H_2PtCl_6$.

Tri-chloro-di-methyl-aniline $C_6H_2Cl_3NMe_2$. [32°]. (257°). From di-methyl-aniline and Cl (K.).—B'HCl.—$B'_2H_2PtCl_6$.

CHLORO-METHYL-BENZENE *v.* CHLORO-TOLUENE.

Chloro-di-methyl-benzene *v.* CHLORO-XYLENE.

Chloro-tri-methyl-benzene *v.* CHLORO-MESITYLENE and CHLORO-ψ-CUMENE.

Chloro-tetra-methyl-benzene *v.* CHLORO-DURENE.

Hexa-chlor-hexa-methyl-benzene $C_{12}H_{12}Cl_6$. [269°]. S.G. ^{15} 1·609. Probably $C_6(CH_2Cl)_6$. Formed by the action of PCl_5 upon $C_6(CH_3)_6$. Colourless, flattened prisms; commences to sublime at 269°; v. sl. sol. ether, or hot $CHCl_3$. In contact with boiling water, made slightly alkaline, it very slowly loses all its chlorine, giving a body of an alcoholic nature, [180°], v. sol. acids; which is sol. alcohol, sl. sol. ether, v. sl. sol. water (Colson, *Bl.* [2] 46, 197).

Hexa-chlor-hexa-methyl benzene $C_{12}H_{12}Cl_6$. [147°]. $C_6(CCl_3)(CH_2Cl)_3(CH_3)_2$. Formed together with the preceding symmetrical isomeride by the action of PCl_5 upon $C_6(CH_3)_6$. Colourless crystals; sol. $CHCl_3$. Boiling water, slightly alkaline, removes its chlorine. The product is an alcohol-acid, probably $C_6(CH_2OH)_3(CH_3)_2(CO_2H)$ (Colson, *Bl.* [2] 46, 198).

TRI-CHLORO-TRI-METHYL-CARBINYL CHLORIDE *v.* TETRA-CHLORO-ISOBUTANE.

TRI-CHLORO-DI-METHYL CARBONATE $CO(OMe)(OCCl_3)$. (91°) at 42 mm. Formed by acting on methyl alcohol with $ClCO_2CCl_3$ (Hentschel, *J. pr.* [2] 36, 314).

Hexa-chloro-di-methyl-carbonate $CO(OCCl_3)_2$. [79°]. Distils undecomposed. Colourless crystals. Prepared by the action of Cl on methyl carbonate (Councler, *B.* 13, 1698).

CHLORO-METHYL-*pseudo*-CARBO-STYRIL *v.* CHLORO-OXY-METHYL-QUINOLINE.

β-CHLORO-α-METHYL CROTONIC ACID $CH_3.CCl:CMe.CO_2H$. [69·5°]. Solidifies at 65°. (210°). From methyl-aceto-acetic ether and PCl_5 (Isbert, *A.* 234, 188). Laminæ (from hot water).

Salts.—MgA'_2 2aq.—ZnA' 1½aq.

Reactions.—1. NaOEt forms the ethyl derivative of β-oxy-α-methyl-crotonic acid.—2. Conc. KOHAq forms methyl ethyl ketone and CO_2: chloro-butylene is not formed as Demarçay asserts.

Ethyl ether EtA'. (173°).

PER-CHLORO-TRI-METHYL-CYANIDINE *v.* *Paranitrile of* TRI-CHLORO-ACETIC ACID

CHLORO-TRIMETHYLENE GLYCOL *v.* Glycerin (β)-chlorhydrin.

CHLORO-METHYL ETHER *v.* Chloro-di-methyl oxide.

CHLORO-METHYL-ETHYL-GLYOXALINE $C_6H_9ClN_2$. *Chloro-oxal-ethyline.* (218°). S.G. ^{15} 1·142. From either di-ethyl-oxamide by PCl_5 (Wallach, *A.* 184, 37; 214, 261). Symmetrical di-ethyl-oxamide gives a good yield, the unsymmetrical a bad yield. CONEtH.CONEtH gives, doubtless, NEt:CCl.CCl:NEt as intermediate product. $CONEt_2.CONH_2$ should give $CCl_2NEt_2.CN$ as intermediate product, but this then changes to CClNEt.CClNEt by intra-molecular change. This view is supported by the production of chloro-oxal-ethyline by the action of PCl_5 on di-ethyl-oxamo-nitrile, $NEt_2.CO.CN$.

Properties.— Liquid, with narcotic odour, v. e. sol. alcohol, ether, ligroïn, and $CHCl_3$. Changed by frequent distillation into an isomeric modification (220°–224°), insol. ligroin. Water at 290° decomposes it, giving NH_3 and NH_2Et.

Reactions.—1. Br in CS_2 or $CHCl_3$ forms B'HBr, $C_6H_8BrClN_2Br_2HBr$ [113°], forming red needles, and $C_6H_8BrClN_2Br_2$ [133°]. Both bodies are unstable, and give, when boiled with water, chloro-bromo-oxal-ethyline.—2. $KMnO_4$ gives oxalic acid.—3. Dilute H_2SO_4 at 240° forms NH_3 and $NEtH_2$.—4. Conc. H_2SO_4 at 220° gives acetic acid.—5. Distilled over *lime* it forms para-oxal-methyline.—6. Na added to its solution in light petroleum forms di-oxal-ethyline, $C_{12}H_{18}N_4$.—7. P and HI at 170° reduces it to oxal-ethyline.

Salts.—$B'_2H_2PtCl_4$.—B'HI aq.—$B'_2H_2ZnCl_4$. B'HBr.—B'HCl aq.—$B'HgCl_2$.—$B'4HgCl_2$.—$B'I_2$ [110°].—$B'AgNO_3$.—$B'H_2C_2O_4$.

Methylo-iodide B'MeI: [205°]; needles (from alcohol).

CHLORO-METHYL-TRI-ETHYL-PHOSPHONIUM CHLORIDE $CH_2Cl.PEt_3Cl$. From methylene chloride and PEt_3 (Hofmann, *Pr.* 11, 290); $CH_2(PEt_3Cl)_2$ being formed at the same time. Formed also by the action of water on the compound of PEt_3 and CCl_4.—$(CH_2Cl.PEt_3Cl)_2PtCl_4$. Slightly soluble needles.

CHLORO-METHYL-GLYOXALINE $C_4H_5ClN_2$. *Chloro-oxalmethyline.* (205°). V.D. 4·1 (obs.). S.G. ^{12} 1·247.

Preparation. — Pure di-methyl-oxamide (10 pts.) is mixed with PCl_5 (33 pts.) in the cold. On warming HCl is evolved. The product is distilled under diminished pressure, and afterwards with steam, and is finally extracted by shaking with $CHCl_3$ (Wallach, *B.* 14, 422; *A.* 214, 308).

Properties.—Liquid; reduced by HI to methyl-glyoxaline.

Salts.—B'HI: needles, sol. water and alcohol.—$B'_2H_2PtCl_6$.

CHLORO-METHYL-GLYOXIM *v.* Chloro-iso-nitroso-acetone oxim.

DI-CHLORO-METHYL-INDOLE

$$C_6H_4{<}\begin{matrix}C(Cl)\\N(CH_3)\end{matrix}{>}CCl$$

[59°]. Long needles. Insol. alkalis. Formed by methylation of chloro-oxindole-chloride (Baeyer, *B.* 15, 786).

CHLORO-METHYL-(PSEUDO)-ISATIN

$$C_6H_3Cl{<}\begin{matrix}CO\\NMe\end{matrix}{>}CO$$

[191°]. Long fine red needles. Sublimable. Formed, together with the formyl derivative of chloro-methyl-amido-benzoic acid, by oxidation of the methylo-chloride of (*B.* 1or3)-chloro-quinoline with $KMnO_4$ (La Coste a. Bodewig, *B.* 18, 429).

TETRA-CHLORO-DI-METHYL-DI-KETONE (?) $CHCl_2.CO.CO.CHCl_2$ [84°]. (202°). A product of the action of $KClO_3$ and HCl on chloranilic acid (Levy a. Jedlicka, *B.* 21, 318). Large yellow tables (from ether). Pungent; sol. water. Forms a phenyl-hydrazide [186°].

PER-CHLORO-METHYL-MERCAPTAN $CCl_3.SCl$ (?). *Tri-chloro-methyl-sulphur chloride. Thiocarbonyl tetrachloride.* (149° uncor.). S.G. 1·722 at 0°; 1·7049 at 11°; 1·6953 at 17½°.

Formation.—1. From methyl sulphocyanide and dry chlorine; the yield is 83 p.c. of the sulphocyanide (James, *C. J.* 51, 272).—2. From CS_2 and chlorine (Rathke, *A.* 167, 180).—3. From $CSCl_2$ and Cl_2.

Preparation.—By passing chlorine (5 mols.) into cooled dry CS_2 (1 mol.) containing a trace of iodine; the product is freed from chloride of sulphur by treatment with water and distillation with steam, and is then fractionated *in vacuo*.

Properties.—Yellow oil, of very unpleasant strong smell. By long heating to its boiling-point it slowly decomposes, probably into CCl_4 and S.

Reactions.—1. By treatment with *chlorine* in presence of iodine it yields CCl_4 and S_2Cl_2.—2. *Alcohol* forms an oil, possibly CS_3Cl_2, and crystals of $C_3H_8O_2$ (126°).—3. *Water* at 160° splits it up into CO_2, HCl, and S. *Alkalis* act in the same way.—4. By heating with *sulphur* at 150°–160° it yields CS_2, CCl_4, $CSCl_2$, per-chloro-methyl tri-sulphide $(CCl_3)_2S_3$ and per-chloro-methyl di-sulphide $(CCl_3)_2S_2$; but the latter appears to be the primary product: $2CCl_3.SCl + S_2 = (CCl_3)_2S_2 + S_2Cl_2$. Per-chloro-methyl-di-sulphide is also formed by heating per-chloro-methyl mercaptan with silver-powder, thus: $2CCl_3.SCl + Ag_2 = (CCl_3)_2S_2 + 2AgCl$ (Klason, *B.* 20, 2376).—5. By $SnCl_2$ it is reduced to $CSCl_2$.—6. HNO_3 (S.G. 1·2) oxidises it to $CCl_3.SO.Cl$.—7. K_2SO_3 gives $C(SH)(SO_3K)_3$.—8. *Aniline* (2 mols.) forms $CCl_3.S.NHPh$; an unstable oil converted by excess of aniline into di-amid-di-phenyl sulphide, di-phenyl-thio-urea, and tri-phenyl-guanidine; and converted by alcoholic KOH into $CCl_2.S.NPh$ (?) [140°] (Rathke, *A.* 167, 211; *B.* 19, 395).—9. The analogous compound $CCl_3.S.NHC_6H_4(CH_3)$ is formed by adding (2 mols. of) *p*-toluidine to its ethereal solution. This body is crystalline, and by boiling with alcohol it is decomposed into *p*-toluidine, CO_2 and H_2S; alcoholic KOH splits off HCl, giving a body [138°], which probably has the constitution $\underbrace{CCl_2.S.N}.C_6H_4Me$ (Rathke, *B.* 19, 395).

HEXA-CHLORO-METHYL-METHYLENE DI-KETONE $(CCl_3.CO)_2.CH_2$; (258°). (c. 192°) at 20 mm. Is the final substitution product obtained by the prolonged action of chlorine upon acetyl-acetone at 120°–130°, and in direct sunlight. Colourless liquid, decomposes when distilled under ordinary pressure. Treated with NaOH (1 mol.) it gives tri-chlor-acetone and sodium tri-chlor-acetate (Combes, *A. Ch.* [6] 12, 238).

ω-CHLORO-(β)-METHYL-NAPHTHALENE $C_{10}H_7.CH_2Cl$. [47°]. (168° at 20 mm.). White glistening plates. Formed by passing chlorine into (β)-methyl-naphthalene heated to about 250° (Schulze, *B.* 17, 1529).

CHLORO-DI-METHYL OXIDE C_2H_5ClO *i.e.* $CH_2Cl.O.CH_3$. (60°). From di-methyl oxide and Cl in daylight (Friedel, *Bl.* [2] 24, 161; 28, 171; *C. R.* 84, 247; Kleber, *A.* 246, 97). Decomposed by water into HCl, MeOH, and formic paraldehyde (trioxymethylene). Ammonia forms hexamethyleneamine. KOAc gives $CH_3.O.CH_2.OAc$ (118°); which is decomposed by water.

Di-chloro-di-methyl oxide $(CH_2Cl)_2O$. (105°). V.D. 3·9 (calc. 4·0). S.G. $\frac{20}{0}$ 1·318. From Me_2O and Cl in daylight (Regnault, *A.* 34, 31; *A. Ch.* [2] 71, 396). Decomposed by boiling water into HCl, formic acid, and formic paraldehyde (Butlerow, *Z.* 1865, 618).

Tetra-chloro-di-methyl oxide $(CHCl_2)_2O$. (130°). V.D. 6·4 (calc. 6·5). S.G. $\frac{20}{0}$ 1·606. From Me_2O and Cl (Regnault, *A. Ch.* [2] 71, 396).

Hexa-chloro-di-methyl oxide $(CCl_3)_2O$. (100°). S.G. 1·597. From Me_2O and Cl in sunshine (Regnault). Decomposed on vaporisation, the V.D. being only 4·67.

Tri-**CHLORO-METHYL-PARACONIC ACID** *v.* TRI-CHLORO-OXY-ETHYL-SUCCINIC ACID.

DI-CHLORO-DI-METHYL-*p*-PHENYLENE-DIAMINE $C_6H_2Cl_2(NMe_2)(NH_2)$ [5:2:4:1]. Formed, together with di-methyl-*p*-phenylene diamine and di-chloro-*p*-phenylene-diamine by boiling nitroso-di-methyl-aniline with HCl (1·2 S.G.). By $K_2Cr_2O_7$ and H_2SO_4 it is oxidised to di-chloro-quinone [159°]. By treatment with Fe_2Cl_6 in presence of H_2S and $ZnCl_2$ it yields di-chloro-methylene blue (Möhlau, *B.* 19, 2010).

CHLORO-METHYL ISOPROPYL KETONE C_5H_9ClO *i.e.* $CH_2Cl.CO.Pr$. (c. 120°). From petroleum pentane (?) or inactive amyl chloride by treatment with CrO_2Cl_2 followed by water (Étard, *C. R.* 84, 127). Insol. water and aqueous KOH; reduces ammoniacal $AgNO_3$. Does not combine with $NaHSO_3$.

TRI-CHLORO-METHYL-PURIN

$C_5(CH_3)Cl_3N_4$ *i.e.*

$$\left.\begin{array}{l} N{:}CCl.C.N \\ |\qquad\quad \| \\ CCl{:}N.C.NMe \end{array}\right\rangle CCl$$

(?) [174°].

Small colourless crystals. Insol. alkalis. Formed by heating di-chloro-oxy-methyl-purin with PCl_5 and $POCl_3$ at 160° for eight hours. Heated with alcoholic NaOH it yields chloro-di-ethoxy-methyl-purin, which by HCl at 130° is converted into methyl-uric acid (Fischer, *B.* 17, 331, 1787).

CHLORO-α-METHYL-PYRIDINE C_6H_6ClN. *Chloro-(α)-picoline.* [21°]. (165° uncor.). S.G. $\frac{20}{0}$ 1·146. Formed by reducing the mixture of penta- and hexa-chloro- picolines obtained by heating comenamic acid with PCl_5. The mixture is heated at 240° with a solution of HI in glacial acetic acid (Ost, *J. pr.* [2] 27, 278).

Properties.—Colourless prisms. Smells like pyridine. Nearly insoluble in water, insoluble in potash, soluble in alcohol and in ether.

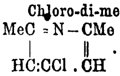
Salts.—B′HCl. Prisms.—$\{B',HCl\}_2PtCl_4$. Needles or prisms.

Chloro-methyl-pyridine C_6H_6ClN. (160°–170°). From potassium methyl-pyrrol and $CHCl_3$ (Ciamician a. Dennstedt, *B.* 14, 1162).—$B'_2H_2PtCl_6$.

Hexa-chloro-methyl-pyridine $C_5HCl_3N(CCl_3)$. [60°]. The chief product of the action of PCl_5 (7 mols.) on comenamic (di-oxy-pyridine carboxylic) acid at 290° (Ost, *J. pr.* [2] 27, 277). May be distilled with steam.

Properties.—Large oblique prisms, or plates (from alcohol). Insol. water, acids and bases.

Chloro-di-methyl-pyridine



$$\begin{array}{l} MeC = N - CMe \\ \ |\qquad\qquad \| \\ \ HC{:}CCl\ .\ CH \end{array}$$

. *Chloro-lutidine.* (178°). S.G. 1·105 at 17°. Formed by heating oxy-di-methyl-pyridine (leitidone) with PCl_5 at 140°; the yield is 50 p.c. Colourless oil. Sl. sol. water.

Salts.—The hydrochloride forms slender needles.—$B'_2H_2Cl_2PtCl_4$: orange crystalline pp.—$B'_2H_2Cl_2HgCl_2$: [155°], sl. sol. water. Chloro-di-methyl-pyridine suspended in water gives characteristic pps. with picric acid $K_2Cr_2O_7$, $CuSO_4$, and $AgNO_3$ (Conrad a. Epstein, *B.* 20, 161).

Tri-chloro-di-methyl-pyridine $C_7H_6Cl_3N$. Formed by chlorinating (β)-lutidine in presence of iodine (Greville Williams, *C. N.* 44, 308).—$B'_2H_2PtCl_6$.

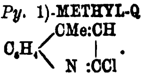
CHLORO-DIMETHYL-PYRIDINE CARBOXYLIC ACID

$$\begin{array}{l} \quad MeC = N - CMe \\ \qquad |\qquad\quad \| \\ HO_2C.C = CCl.C.CO_2H \end{array}$$

. *Chloro-lutidine-di-carboxylic acid.* [c. 224°]. Formed by the action of PCl_5 upon oxy-di-methyl-pyridine-di-carboxylic acid (lutidone-di-carboxylic acid) at 140°. White prisms. Sol. hot water (Conrad a. Epstein, *B.* 20, 164).

Penta-chloro-tri-methyl-pyridine di-carboxylic ether. *Di-chloride.* [150°]. From hydro-tri-methyl-pyridine di-carboxylic ether by chlorination (Hantzsch, *A.* 215, 19). Woolly needles (from alcohol).

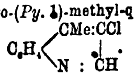
(*Py.* 3)-**CHLORO**-(*Py.* 1)-**METHYL-QUINOLINE** $C_{10}H_8NCl$ *i.e.*



$$C_6H_4\left\langle\begin{array}{l} CMe{:}CH \\ \qquad | \\ N\ {:}CCl \end{array}\right.$$

. [59°]. (296° cor.). From (*Py.* 3)-oxy-(*Py.* 1)-methyl-quinoline and PCl_5 (Knorr, *A.* 236, 97). Mass of slender needles (from dilute alcohol); v. sl. sol. water, v. sol. alcohol and ether; volatile with steam.—$B'_2H_2PtCl_6$ 2aq. Reduced by HI to (*Py.* 1)-methyl-quinoline. Water at 160° has no action: at 200° it converts it into oxy-methyl-quinoline.

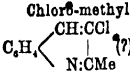
(*Py.* 2)-**Chloro**-(*Py.* 1)-**methyl-quinoline** C_9H_5MeClN *i.e.*



$$C_6H_4\left\langle\begin{array}{l} CMe{:}CCl \\ \qquad\ | \\ N\ :\ CH \end{array}\right.$$

. [54°]. From skatole, chloroform, and alcoholic NaOH (Magnanimi, *G.* 17, 252). Delicate needles. Its picric acid compound melts at 208°, and its aurochloride at 164°.

Chloro-methyl-quinoline C_9H_5MeClN *i.e.*



$$C_6H_4\left\langle\begin{array}{l} CH{:}CCl \\ \qquad | \\ N{:}CMe \end{array}\right.$$

(?). [71°]. From methyl-ketole, chloroform, and alcoholic NaOH, thus:

$$C_8H_6MeN + 2NaOH + CHCl_3$$
$$= C_9H_5MeClN + 2NaCl + 2H_2O$$

(Magnanimi, *G.* 17, 249). White needles, insol. water, sol. alcohol and ether. The picric acid compound forms pale yellow needles [223°].

(*Py* 1)-Chloro-(*Py.* 3)-methyl-quinoline C_9H_5MeClN *i.e.*  $C_6H_4<\begin{matrix}CCl:CH\\ |\\ N:CMe\end{matrix}$. (γ)-*Chloro-quinaldine*. [43°]. (270°). From PCl_5 and oxy-methyl-quinoline, the product of condensation of aceto-acetic ether with aniline (Conrad a. Limpach, *B.* 20, 944). Water at 220° gives oxy-methyl-quinoline. HI in HOAc at 260° gives methyl-quinoline. The picric acid compound melts at 178°.—$B'_2H_2PtCl_6$.—B'HBr.

(*B.* 4)-Chloro-(*B.* 1)-methyl-quinoline C_9H_5MeClN *i.e.*  $\begin{matrix}CH:CMe.C.CH:CH\\ |\quad\quad \| \quad\quad |\\ CH:CCl.C.N:CH\end{matrix}$. [49°]. From (6, 3, 1)-chloro-*m*-toluidine, nitro-benzene, glycerin, and H_2SO_4 (Gattermann a. Kaiser, *B.* 18, 2603). Needles; v. sol. alcohol, ether, and benzene. HI in HOAc converts it at 250° into (*B.* 1)-methyl-quinoline. The picric acid compound melts at 172°.—$B'HCl.HgCl_2$.—$B'_2H_2PtCl_6$.

(*Py.* 3)-Chloro-(*Py.* 2,3)-di-methyl-quinoline  $C_6H_4<\begin{matrix}CMe:CMe\\ |\\ N=CCl\end{matrix}$. [131°]. From oxy-di-methyl-quinoline and PCl_5 (Knorr, *A.* 245, 360). Crystals (from alcohol). Water at 200° forms again the di-methyl-carbostyril.—$B'_2H_2PtCl_6$ 4aq.

(*Py.* 1)-Chloro-(*Py.* 3; *B.* 2·4)-tri-methyl-quinoline $C_9H_3NClMe_3$. *o-p-Di-methyl-γ-chloro-quinaldine.* [114°]. (298°). Formed by the action of PCl_5 in presence of $POCl_3$ on (*Py.* 1:3; *B.* 2:4)-Oxy-tri-methyl-quinoline (Conrad a. Limpach, *B.* 21, 527). Flat prisms (from ether). Sublimes easily. Almost insol. water, v. sol. dilute acids, alcohol, ether, and benzene. On heating with aniline the chlorine is replaced by NHPh.—$(B'HCl)_2PtCl_4$: Needles; v. sl. sol. hot water.

Di-chloro-(*Py.* 3)-methyl-quinoline  $C_6H_2Cl_2<\begin{matrix}CH:CH\\ |\\ N:CMe\end{matrix}$. *Di-chloro-quinaldine.* [46°]. (300°). Obtained by heating di-chloro-*o*-amido-benzaldehyde with sodium acetate and aqueous NaOH (Gnehm, *B.* 17, 755).

Di-chloro-(*B.* 1)-methyl-quinoline $C_9H_4NMeCl_2$. [275°]. Formed by dissolving (*B.* 1)-methyl-quinoline in boric acid and treating this with a solution of bleaching powder (Einhorn a. Lauch, *A.* 243, 361). Needles (from acetic ether).

(*Py.* 1:2:3)-Tri-chloro-(*B.* 4)-methyl-quinoline  $C_6H_3(CH_3)<\begin{matrix}CCl:CCl\\ |\\ N:CCl\end{matrix}$. *Tri-chloro-toluquinoline.* [112°]. Formed by heating (*Py.* 2:3:1)-di-chloro-oxy-(*B.* 4)-methyl-quinoline with PCl_5 at 125°. Long colourless needles. Very volatile with steam. Peculiar smell (Rügheimer a. Hoffmann, *B.* 18, 2985).

(*Py.* 1:2:3)-Tri-chloro-(*B.* 2)-methyl-quinoline  $C_6H_3(CH_3)<\begin{matrix}CCl:CCl\\ |\\ N:CCl\end{matrix}$. *Tri-chloro-toluquinoline.* [134°]. *Formation.*—1. By the action of PCl_5 upon malon-phenyl-amic acid.—2. The acid malonate of *p*-toluidine (5 g.) is covered with benzene (50 g.) and PCl_5 (25 g.) slowly added; after standing for some time the reaction is completed by heating to boiling.

Properties.—Long colourless needles. Sol. alcohol, ether, benzene, &c., insol. water. Volatile with steam. Peculiar smell. Weak base (Rügheimer a. Hoffmann, *B.* 17, 740; 18, 2975, 2979).

(*Py.* 2:4:1)-DI-CHLORO-METHYL-ISO-QUINOLINE  $C_6H_4<\begin{matrix}CMe=CCl\\ |\\ CCl=N\end{matrix}$. [102°]. Formed by the action of $POCl_3$ upon the imide of phenyl-methyl-acetic-*o*-carboxylic acid  $C_6H_4<\begin{matrix}CHMe.CO\\ |\\ CO-NH\end{matrix}$. Long flat needles (Gabriel, *B.* 20, 2504).

DI-CHLORO-DI-METHYL-SUCCINIC ACID $C_6H_8Cl_2O_4$ *i.e.* $CO_2H.CClMe.CClMe.CO_2H$. *Di-chloro-adipic acid.* [185°]. Formed, together with pyrocinchonic acid, by the action of 'molecular' silver upon α-di-chloro-propionic acid in benzene solution (Otto a. Beckurts, *B.* 18, 847). Small crystals. Sublimable. V. sol. water and alcohol, v. sl. sol. benzene.

Reactions.—By further action of 'molecular' silver it is converted into pyrocinchonic acid $CO_2H.CMe:CMe.CO_2H$. On reduction it gives as chief product di-methyl-succinic acid $CO_2H.CHMe.CHMe.CO_2H$ [194°]. By the action of alcoholic KOH, or by heating the silver salt with water, chlorotiglic acid $C_4H_6Cl(CO_2H)$ is formed of melting-point [69°].

Salts.—$A''Na_2$: plates.—$A''K_2$ 2aq: plates.—$A''Ag_2$: white crystalline pp.

PER-CHLORO-METHYL-DI-SULPHIDE $(CCl_3)_2S_2$. (135° *in vacuo*). Obtained by the action of silver-powder upon per-chloro-methyl-mercaptan: $2CCl_3.SCl + Ag_2 = (CCl_3)_2S_2 + 2AgCl$. Also formed by heating per-chloro-methyl-mercaptan with sulphur. Thick yellowish oil, of slight turpentine-like smell. By distillation at the ordinary pressure it decomposes into $CCl_3.SCl$, $CSCl_2$, and other products. By heating with sulphur at about 170° it yields per-chloro-methyl tri-sulphide $(CCl_3)_2S_3$ (Klason, *B.* 20, 2379).

Per-chloro-methyl-tri-sulphide $(CCl_3)_2S_3$. [57°]. (190° *in vacuo*). Formed by heating per-chloro-methyl di-sulphide with sulphur at 170° (Klason, *B.* 20, 2380); or by passing chlorine into CS_2 containing iodine (Rathke, *A.* 167, 209). Flat prisms; v. e. sol. ether, CS_2, and warm alcohol. On distillation at the ordinary temperature it decomposes into $CCl_3.SCl$, $CSCl_2$, S, and other products.

TRI-CHLORO-METHYL-SULPHUR-CHLORIDE *v.* PER-CHLORO-METHYL-MERCAPTAN.

CHLORO-METHYL-UREA.

Acetyl derivative $C_4H_6Cl_2N_2O_2$ *i.e.* $CH_2Cl.NH.CO.NH.CO.CH_2Cl$. [180°]. From chloro-acetamide, Br, and aqueous KOH (Hofmann, *B.* 18, 2735). Decomposed by acids and alkalis into formic aldehyde and chloro-acetic acid.

CHLORO-MUCONIC ACID *v.* MUCONIC ACID.

(α)-CHLORO-NAPHTHALENE $C_{10}H_7Cl$ *i.e.*  $C_6H_4<\begin{matrix}CCl:CH\\ |\\ CH:CH\end{matrix}$. (251°) (F. a. S.); (263°) (Atterberg, *Bl.* [2] 28, 509). S.G. ^{14} 1·20 (C.).

Formation.—1. By heating (α)-diazonaphthalene with a large excess of HCl; the yield is

88 p.c. of the theoretical (Gasiorowski a. Waÿss, *B.* 18, 1939).—2. By boiling naphthalene dichloride $C_{10}H_8Cl_2$ with alcoholic KOH (Laurent, *A.* 8, 13; Faust a. Saame, *A.* 160, 68; *Z.* [2] 5, 705).—3. By the action of PCl_5 on (α)-nitro-naphthalene (De Koninck a. Marquart, *B.* 5, 11) or on naphthalene (α)-sulphonic acid (Carius, *A.* 114, 145). 4. From (α)-nitro-naphthalene and Cl (Atterberg, *B.* 9, 317, 927).

Preparation.—By chlorinating naphthalene, washing with alcoholic potash and fractionating (Roux, *Bl.* [2] 45, 515).

Properties.—Liquid, not solid at −17°. In CS_2 solution it is not much acted upon by Al_2Cl_6, but if (α)-chloro-naphthalene is warmed with 20 p.c. of its weight of Al_2Cl_6, some naphthalene and tarry matters are produced together with the (β)- compound. In this reaction, therefore, it behaves in a similar manner to (α)-bromonaphthalene. **Picric acid compound** [137°].

(β)-Chloro-naphthalene  $C_6H_4\left\langle\begin{matrix}CH:CCl\\ |\\ CH:CH\end{matrix}\right.$ [57°]. (252°); (265° cor.). S.G. ^{18} 1·266 (R.).

Formation.—1. By heating (β)-diazonaphthalene with a large excess of HCl; the yield is 45 p.c. of the theoretical (Gasiorowski a. Waÿss, *B.* 18, 1940; *cf.* Liebermann a. Palm, *A.* 183, 270).—2. By the action of PCl_5 on (β)-naphthol or on naphthalene (β)-sulphonic acid (Rimarenko, *B.* 9, 663; Clève, *Bl.* [2] 25, 257).—3. From $Hg(C_{10}H_7)_2$ and $SOCl_2$ (Heumann a. Köchlin, *B.* 16, 1627).—4. By intra-molecular change from (α)-chloro-naphthalene (*q. v.*).

(1:2)-Di-chloro-naphthalene $C_{10}H_6Cl_2$ [1:2] [35°]. Formed by dropping a solution of potassium nitrite (4 g.) in water (20 c.c.) into a boiling solution of (α)-chloro-(β)-naphthylamine hydrochloride (10 g.) and cuprous chloride (5 g.) in hydrochloric acid; yield—4 g. Also from (α)-chloro-(β)-naphthol and PCl_5 and from chloro-(α)-naphthylamine (obtained by reduction of di-chloro-α-naphthylamine) by replacing NH_2 by Cl. Monosymmetric tables, $a:b:c = 1{\cdot}5196:1:?$, $\beta = 76° 46'$ (Clève, *B.* 20, 1991). On nitration it yields di-chloro-di-nitro-naphthalene [170°]. CrO_3 forms di-chloro-naphthoquinone [181°].

(η)- or (1, 3′)-Di-chloro-naphthalene $C_{10}H_6Cl_2$. [48°]. From naphthalene (β)-sulphonic acid by nitration and treatment of the resulting (β)-nitro-naphthalene (β-)-sulphonic acid with PCl_5 (Clève, *Bl.* [2] 29, 499). Also from (β)-naphthylamine (γ)-sulphonic acid by exchanging NH_2 for Cl and treating the product with PCl_5 (Forsling, *B.* 20, 2105). Also from ('β')-naphthalene-di-sulphonic acid and PCl_5 (Armstrong a. Wynne); and synthetically from *m*-chloro-phenyl-isocrotonic acid (Erdmann a. Kirchhoff). Oxidation by HNO_3 gives chloro-phthalic and nitro-phthalic acids.

(θ) or (1:3)-Di-chloro-naphthalene

 $C_6H_4\left\langle\begin{matrix}CCl:CH\\ CH:CCl\end{matrix}\right\rangle$. [61° uncor.]. (286° uncor.).

Formation.—1. From (δ)-nitro-naphthalene (β)-sulphonic acid and PCl_5 (Clève, *Bl.* [2] 29, 415). — 2. From di-chloro-(α)-naphthylamine [82°] by the diazo- reaction.

Properties.—Flat glistening plates, or slender white needles; may be sublimed. By HNO_3 it is oxidised to phthalic acid (Clève, *B.* 20, 449). The so-called 'α'-di-chloro-naphthalene [38°] is a mixture of the θ and 'β'- isomerides. It gives a sulphochloride [148°].

Di-chloro-naphthalene $C_{10}H_6Cl_2$ [1:2′]. [64°].

Formation.—1. From β-chloro-naphthalene sulphonic acid and PCl_5 (Arnell, *Bl.* [2] 45, 184; Armstrong a. Wynne, *C. J. Proc.* 4, 106).—2. From (β)-naphthol-('α')-sulphonic acid (Bayer's acid) by heating with PCl_5 (Claus a. Volz, *B.* 18, 3157).—3. From (β)-naphthylamine-('α')-sulphonic acid (Badische acid) (Forsling).—4. From chloro-β-naphthol [101°] and PCl_5 (C. a. V.).—5. From *p*-chloro-phenyl-paraconic acid (Erdmann a. Kirchhoff, *A.* 247, 379).

It gives a sulphochloride [119°].

('β') or (1,4)-Di-chloro-naphthalene

$C_{10}H_6Cl_2$ *i.e.*  $C_6H_4\left\langle\begin{matrix}CCl:CH\\ |\\ CCl:CH\end{matrix}\right.$. [68°]. (287°).

Formation.—1. By distillation of naphthalene tetrachloride (Krafft a. Becker, *B.* 9, 1089; Faust a. Saame, *A.* 160, 70).—2. From naphthalene and Cl_2O (Hermann, *A.* 151, 63).—3. From (α)-chloro-naphthalene in $CHCl_3$ and Cl (Widmann, *Bn.* II, 139).—4. By the action of PCl_5 on (α)-nitro-(α)-naphthol (Atterberg, *B.* 9, 1189), on bromo-naphthalene sulphonic acid (Jolin, *Bl.* [2] 28, 516), or on chloro-naphthalene sulphonic acid, obtained from (α)-naphthylamine-*p*-sulphonic acid (Cleve, *Bl.* [2] 26, 242).

Properties.—Needles (from alcohol). Boiling dilute HNO_3 forms di-chloro-phthalic acid. CrO_3 in HOAc gives di-chloro-naphthoquinone [174°].

(ζ) or *Peri*-Di-chloro-naphthalene $C_{10}H_6Cl_2$,

probably 
(Ekstrand, *B.* 18, 2881). [83°].

Formed in small quantity on distilling 'β'-di-nitro-naphthalene with PCl_5 (Atterberg, *B.* 9, 1732). Formed also by nitrating (γ)-di-chloro-naphthalene, reducing this to chloro-naphthylamine [91°] and displacing NH_2 by Cl (Atterberg, *B.* 10, 548). Prisms.

(κ)-Di-chloro-naphthalene $C_{10}H_6Cl_2$. [94° uncor.]. Formed by heating (α)-naphthol sulphonic acid with PCl_5 (Claus a. Oeler, *B.* 15, 314). On moderate oxidation it gives (α)-naphthoquinone and by further oxidation phthalic acid.

(γ)-Di-chloro-naphthalene $C_{10}H_6Cl_2$ [1:4′]? (Ekstrand, *B.* 18, 2881). [107°]. Formed by the action of PCl_5 on (α)-nitro-naphthalene, or, better, on ('α')-di-nitro-naphthalene (Atterberg, *B.* 9, 317, 1188, 1734), and on (α)-nitro-naphthalene (α)-sulphonic acid (Cleve, *Bl.* [2] 24, 506). Also from (α)-naphthylamine sulphonic acid (Laurent's naphthalidinic acid) by diazotisation and distillation of the resulting diazo-naphthalene sulphonic acid with PCl_5 (Erdmann, *B.* 20, 3185). Formed synthetically from *o*-chloro-phenyl-paraconic acid. Scales. Gives a nitro-derivative [142°], and a di-nitro-derivative [246°]. Oxidation by HNO_3 gives chloro-nitro-phthalic acid. CrO_3 in HOAc gives *c*-chloro-phthalic acid [184°] (Guareschi, *G.* 17, 119).

(δ)-Di-chloro-naphthalene $C_{10}H_6Cl_2$. [114°]. From naphthalene-('α')-di-sulphonic acid and PCl_5 (Clève, *Bl.* [2] 26, 244). Large tables; v. sol. boiling alcohol. Dilute HNO_3 gives chloro-phthalic acid. It is perhaps $C_{10}H_6Cl_2$ [2:2′].

(ι)-Di-chloro-naphthalene $C_{10}H_6Cl_2$. [120°]. From naphthalene tetrachloride (4 pts.) and

Ag_2O (3 pts.) at 200° (Leeds a. Everhart, *Am.* 2, 211). Formed, in very small quantity, when $C_{10}H_6Cl_4$ is decomposed by alcoholic KOH (Widmann, *B.* 15, 2162). Very thin laminæ; sl. sol. cold alcohol.

(ε) or (2, 3′)?-Di-chloro-naphthalene $C_{10}H_6Cl_2$. [136°]. (285° uncor.).

Formation.—1. By distilling (β)-chloro-naphthalene-sulphonic chloride with PCl_5; the chloro-naphthalene-sulphonic acid being obtained either by sulphonation of (β)-chloro-naphthalene or by the action of cuprous chloride upon the diazo-compound from the (β)-naphthylamine sulphonic acid obtained from (β)-naphthol sulphonic acid and NH_3 (Forsling, *B.* 20, 81; Arnell, *Bl.* [2] 45, 184).—2. From naphthalene (‘β’)-disulphonic acid, and from (β)-naphthol (α)-sulphonic acid by distilling with PCl_5 (Clève, *Bl.* [2] 25, 244; Armstrong a. Graham, *C. J.* 39, 142; Claus a. Zimmermann, *B.* 14, 1483). Needles (by sublimation) or large monoclinic tables (from alcohol). Volatile with steam. Sol. ether, chloroform, and benzene, sl. sol. alcohol. On oxidation it gives chloro-phthalic acid $C_6H_3Cl(CO_2H)_2$ [4:2:1] and (‘β’)-di-chloro-(α)-naphthoquinone [149°] (Claus a. Müller, *B.* 18, 3073).

(ζ)-Tri-chloro-naphthalene $C_{10}H_5Cl_3$. [56°]. Prepared by heating di-chloro-naphthalene (β)-sulphonic chloride with PCl_5 (Widmann, *B.* 12, 962). Fine white needles. Insol. water, sl. sol. hot alcohol, v. sol. benzene.

(ε)-Tri-chloro-naphthalene $C_{10}H_5Cl_3$. [65°]. From η-di-chloro-naphthalene by nitration and treatment of the resulting $C_{10}H_5Cl_2(NO_2)$ with PCl_5 (Clève, *Bl.* [2] 29, 500). Needles, v. sol. alcohol.

(θ)-Tri-chloro-naphthalene $C_{10}H_5Cl_3$. [76°]. From nitro-naphthalene (‘α’)-di-sulphonic acid and PCl_5 at 225° (Alén, *Bn.* II, 140). Small needles (from HOAc). V. sol. alcohol, m. sol. boiling HOAc.

(‘α’)-Tri-chloro-naphthalene $C_{10}H_5Cl_3$. [82°].

Formation.—1. By the action of alcoholic KOH upon (α)-chloro-naphthalene-tetra-chloride (Faust a. Saame, *A.* 160, 71).—2. By heating (α)-naphthol-di-sulphonic chloride with PCl_5 (3 mols.) at 170°–180° (Claus a. Mielcke, *B.* 19, 1182).

Properties.—Colourless needles. V. sol. chloroform, ether, and hot alcohol. HNO_3 at 200° gives tri-chloro-nitro-phthalic acid (Widmann, *Bl.* [2] 28, 511).

(‘β’)-Tri-chloro-naphthalene  $C_6H_4\left<\begin{matrix}CCl:CCl\\ |\\ CH:CCl\end{matrix}\right.$ [90° uncor.]. (above 360°).

Formation.—1. By heating di-chloro-(α)-naphthol [101°], or sodium (α)-naphthol (β)-sulphonate with PCl_5 at 130°–140° (Claus a. Knyrim, *B.* 18, 2926).—2. By chlorinating (α)-nitro-naphthalene (Atterberg, *B.* 9, 926).

Properties.—Needles (from alcohol). May be sublimed. Insol. water, v. sol. other solvents.

Tri-chloro-naphthalene $C_{10}H_5Cl_3$. [90°]. Formed together with di-chloro-(β)-naphthol [125°], by heating sodium (β)-naphthol (β)-disulphonate with 5 mols. of PCl_5 at 210°.

Properties.—Fine white needles. Sublimable. V. sol. ether, benzene, etc., and hot alcohol, sl. sol. cold alcohol. Heated with nitric acid (S.G. 1·16), at 210° it yields a syrupy di-chloro-phthalic acid. By CrO_3 it is oxidised to the same di-chloro-phthalic acid, together with a tri-chloro-(α)-naphthoquinone which gives an anilide $C_{10}H_3Cl_2(NHPh)O_2$ which melts at [228°]. Hence it appears to be different from the tri-chloro-naphthalene of melting-point [90°] already known (Claus a. Schmidt, *B.* 19, 3174).

(γ)-Tri-chloro-naphthalene $C_{10}H_5Cl_3$. [103°]. Long white needles. Prepared by distillation of dichloro-naphthalene-(α)-sulphonic chloride with PCl_5 (Widmann, *B.* 12, 2230). Formed also by chlorinating (α)-nitro-naphthalene (Atterberg, *B.* 9, 317). Prisms. By heating to 170° with HNO_3 (1·42) it gives di-nitro-di-chloro-phthalic acid.

(η)-Tri-chloro-naphthalene $C_{10}H_5Cl_3$. [113°]. From nitro-naphthalene (β)-disulphonic chloride and PCl_5 at 190° (Alén, *Bn.* II, 140). Needles (from HOAc). V. sol. warm alcohol; v. e. sol. benzene. Volatile with steam.

(δ)-Tri-chloro-naphthalene $C_{10}H_5Cl_3$. [181°]. Formed by the action of PCl_5 on (‘β’)-di-nitro-naphthalene, nitro-(γ)-di-chloro-naphthalene, (‘α’) chloro-di-nitro-naphthalene [106°], (‘β’)-chloro-di-nitro-naphthalene, and nitro-(‘β’)-di-chloro-naphthalene (Atterberg, *B.* 9, 1187, 1733; Widmann, *Bl.* [2] 28, 511). Long needles. Oxidation gives di-chloro-phthalic acid.

(‘α’)-Tetra-chloro-naphthalene $C_{10}H_4Cl_4$. [130°]. Formed by the action of alcoholic KOH on the (‘α’)-di-chloro-naphthalene (‘α’)-tetra-chloride, obtained by chlorinating naphthalene (Faust a. Saame, *A.* 160, 72). Formed in the same way from (‘β’)-di-chloro-naphthalene tetra-chloride, and from (‘β’)-tri-chloro-naphthalene dichloride (Widmann, *Bl.* [2] 28, 511). Long needles. Oxidation gives di-chloro-phthalic acid.

Tetra-chloro-naphthalene $C_{10}H_4Cl_4$ *i.e.*  $C_6H_4\left<\begin{matrix}CCl:CCl\\ |\\ CCl:CCl\end{matrix}\right.$ (?). [140° uncor.]. Formed by heating (α)-naphthol-tri-sulphonic chloride with PCl_5 (4 mols.) at 210°–250°. Sublimes in colourless feathery needles. Crystallises from toluene in long thin needles. V. sol. hot alcohol, ether, chloroform, &c., sl. sol. cold alcohol, insol. water. On oxidation with CrO_3 or HNO_3 it is converted into di-chloro-(α)-naphthoquinone [189°],  $C_6H_4\left<\begin{matrix}CO.CCl\\ \|\\ CO:CCl\end{matrix}\right.$, together with chlorinated phthalic acids (Claus a. Mielcke, *B.* 19, 1184).

Tetra-chloro-naphthalene $C_{10}H_4Cl_4$. [141°]. Formed by the action of alcoholic KOH on (γ)-di-chloro-naphthalene tetrachloride [85°], and on tri-chloro-naphthalene di-chloride [93°] (Atterberg a. Widmann, *B.* 10, 1842). Slender needles; sl. sol. alcohol. May be identical with the preceding.

(ζ)-Tetra-chloro-naphthalene $C_{10}H_4Cl_4$. [160·5°]. Formed by acting on (ε)-di-chloro-di-nitro-naphthalene with PCl_5 (Alén, *Bl.* [2] 36, 435). Interlacing needles.

(γ)-Tetra-chloro-naphthalene $C_{10}H_4Cl_4$. [176°]. Obtained by the action of alcoholic KOH on (‘α’)-di-chloro-naphthalene (‘α’)-tetra-chloride got by chlorinating naphthalene (Widmann, *B.* 10, 1724; *Bl.* [2] 28, 512). Flat needles, sl. sol. alcohol.

(ε)-Tetra-chloro-naphthalene $C_{10}H_4Cl_4$. [180°]. From di-nitro-(γ)-di-chloro-naphthalene by distilling with PCl_5 (Atterberg a. Widmann, *B.* 10, 1843). Long needles; sl. sol. alcohol.

('β')-**Tetra-chloro-naphthalene** $C_{10}H_4Cl_4$. [194°]. Formed by chlorinating nitro-naphthalene (Atterberg, *B.* 9, 318). Needles, v. sl. sol. alcohol.

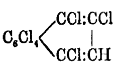
Penta-chloro-naphthalene $C_{10}H_3Cl_5$ *i.e.*

$C_6Cl_4<\begin{matrix}CH:CH\\ |\\ CCl:CH\end{matrix}$. [169°]. (above 360°). Prepared by heating di-chloro-(α)-naphthoquinone with twice its weight of PCl_5 to 250° (Graebe, *A.* 149, 8; Claus a. Lippe, *B.* 16, 1016). Needles (from alcohol). On oxidation with fuming HNO_3 at 110° it gives tetra-chloro-naphthoquinone. Dilute HNO_3 at 100° gives tetra-chloro-phthalic acid.

('β')-**Penta-chloro-naphthalene** $C_{10}H_3Cl_5$. [177°]. From nitro-(δ)-tetra-chloro-naphthalene and PCl_5 (Atterberg a. Widmann, *B.* 10, 1843). Needles. Oxidises to tri-chloro-phthalic acid.

Hexa-chloro-naphthalene $C_{10}H_2Cl_6$. [143°]. Formed by chlorinating tri-chloro-naphthalene (Laurent). Six-sided columns; v. sl. sol. alcohol, m. sol. ether. May be oxidised to hexa-chloro-naphthoquinone.

(β)-**Hepta-chloro-naphthalene**



$C_6Cl_4<\begin{matrix}CCl:CCl\\ |\\ CCl:CH\end{matrix}$ [194° uncor.]. Formed by heating tetra-chloro-(α)-naphthoquinone (1 pt.) with PCl_5 (2 pts.) for 6 or 8 hrs. at 250°. Small colourless needles. Sublimable. By heating with HNO_3 (1·5 S.G.) it is oxidised to penta-chloro-(α)-naphthoquinone [217°], and tetra-chloro-phthalic acid [250°] (Claus a. Wenzlik, *B.* 19, 1165; *cf.* Claus a. Lippe, *B.* 16, 1019)

Per-chloro-naphthalene $C_{10}Cl_8$. [203° uncor.]. (403°). Formed by heating tetra-chloro-oxy-naphthoquinone [265°], penta-chloro-(α)-naphthoquinone [217°], or (α)-naphthol-tri-sulphonic chloride, with PCl_5 at 250°. Prepared by the protracted chlorination of naphthalene in presence of $SbCl_5$ (Berthelot a. Jungfleisch, *Bl.* [2] 9, 446; *A. Ch.* [4] 15, 332). Colourless needles. Sublimable (Claus a. Wenzlik, *B.* 19, 1169; Claus a. Mielcke, *B.* 19, 1186). By heating with $SbCl_5$ at 290° it is split up into C_6H_6, C_2Cl_6, and CCl_4 (Ruoff, *B.* 9, 1048). It is partially converted into naphthalene by passing with hydrogen through a red-hot tube.

DI-CHLORO-NAPHTHALENE TETRA-BROMIDE $C_{10}H_6Cl_2Br_4$. [c. 100°]. From di-chloro-naphthalene and Br.

(α)-CHLORO-NAPHTHALENE TETRA-CHLORIDE $C_{10}H_7Cl_5$. [131°]. Formed by the action of Cl on naphthalene (Faust a. Saame, *A.* 160, 67) or on (α)-chloro-naphthalene (Widmann, *B.* 10, 1724; *Bl.* [2] 28, 505). Monoclinic prisms (from chloroform). Oxidation gives phthalic acid. Alcoholic KOH forms ('α')-tri-chloro-naphthalene.

(β)-**Chloro-naphthalene tetra-chloride** $C_{10}H_7Cl_5$. From (β)-chloro-naphthalene and Cl (W.). Oil.

Di-chloro-naphthalene tetra-chloride $C_{10}H_6Cl_6$. [85°]. From (γ)-di-chloro-naphthalene and Cl (Atterberg a. Widmann, *B.* 10, 1841). Prisms. Alcoholic KOH gives (δ)-tetra-chloro-naphthalene.

Di-chloro-naphthalene tetra-chloride $C_{10}H_6Cl_6$. [172°]. Formed by the action of Cl on ('α') or ('β')-di-chloro-naphthalene (Widmann, *Bl.* [2] 28, 506). Monoclinic prisms (from $CHCl_3$). V. e. sol. HOAc and benzene. Oxidation gives di-chloro-phthalic acid. Alcoholic KOH gives ('α') tetra-chloro-naphthalene.

Di-chloro-naphthalene tetra-chloride $C_{10}H_6Cl_6$. Formed, together with the preceding, by the union of Cl with ('α')-di-chloro-naphthalene. Oil. Alcoholic KOH gives (γ)-tetra-chloro-naphthalene.

('α')-**Tri-chloro-naphthalene di-chloride** $C_{10}H_5Cl_5$. [93°]. From (γ)-di-chloro-naphthalene and Cl (Atterberg a. Widmann, *B.* 10, 1842). Alcoholic KOH converts it into (δ)-tetra-chloro-naphthalene.

('β')-**Tri-chloro-naphthalene di-chloride** $C_{10}H_5Cl_5$ [152°]. Formed, together with $C_{10}H_5Cl_5HOAc$ [195°], by passing chlorine into a solution of (α)-chloro-naphthalene in glacial HOAc (Widmann, *Bl.* [2] 28, 507). Short prisms, sl. sol. alcohol.

CHLORO-NAPHTHALENE SULPHINIC ACID $C_{10}H_6Cl.SO_2H$. Formed by the action of sodium amalgam on (α)-chloro-naphthalene sulphonic bromide (?) [115°] obtained from bromo-naphthalene sulphonic acid by PCl_5 (Gessner, *B.* 9, 1504). Slender needles (from alcohol).—BaA'_2 1½aq.

(α)-CHLORO-NAPHTHALENE (α)-SULPHONIC ACID $C_{10}H_7ClSO_3$ *i.e.* $C_{10}H_6Cl(SO_3H)$ [1:4]. Obtained by heating (α)-diazo-(α)-naphthalene-sulphonic acid with HCl. V. sol. colourless tables (containing 2aq).

Salts.—A'K: silvery needles.—A'Na: thin scales.—A'Ag: thin tablets, v. sl. sol. cold water. A'_2Ba aq: sparingly soluble powder.

Ethyl ether A'Et: [46°]; large monosymmetrical prisms, $a:b:c = 1·6785:1:?$, $\beta = 68° 58'$.

Chloride $C_{10}H_6Cl(SO_2Cl)$: [95°]; large crystals (from chloroform).

Amide $C_{10}H_6Cl(SO_2NH_2)$: [226°]; sparingly soluble silvery scales (Clève, *B.* 20, 72).

(α)-**Chloro-naphthalene** (β)-**sulphonic acid** $C_{10}H_7ClSO_3$ *i.e.* $C_{10}H_6Cl(SO_3H)$ [1 : 2′or3′]. Obtained by the action of Cu_2Cl_2 upon the diazo-compound of the naphthylamine sulphonic formed by reduction of the 'β'-nitro-naphthalene (β)-sulphonic acid (sparingly soluble Ba salt), which is one of the products of the nitration of naphthalene (β)-sulphonic acid.

Properties.—V. sol. colourless rhombic tables. When heated in a current of steam it yields (α)-chloro-naphthalene.

Salts.—A'Ag: thin glistening tables, sol. hot water, sl. sol. cold.—A'_2Ba aq: sparingly sol. crystalline powder.

Ethyl ether A'Et: [111°]; monosymmetrical crystals, $a:b:c = ·4307:1:?$, $\beta = 86° 45'$; v. e. sol. hot alcohol.

Chloride $C_{10}H_6Cl(SO_2Cl)$: [114°]; small scales.

Amide $C_{10}H_6Cl(SO_2NH_2)$: [216°]; thin plates (Clève, *B.* 20, 74).

(α)-**Chloro-naphthalene** *p*-**sulphonic acid** $C_{10}H_7ClSO_3$ *i.e.* $C_{10}H_6Cl(SO_3H)$ [1:4].

Formation.—1. By sulphonation of (α)-chloro-naphthalene (Zinin, *J. pr.* 33, 36).—2. From (α)-naphthylamine-*p*-sulphonic acid (naphthionic acid) by the action of Cu_2Cl_2 upon its diazo- compound.

Properties.—Silvery plates. Converted by Br into chloro-bromo-naphthalene [67°].

Salts. — KA'. — BaA'_2. — ZnA'_2 6aq. — CuA'_2 7aq.—AgA' aq (Arnell, *Bn.* ii. 153).

Ethyl ether EtA': [104°]; large thin monoclinic tables, $a:b:c = 1{\cdot}3281:1:1{\cdot}1262$, $\beta = 80°\ 59'$.

Chloride $C_{10}H_6Cl(SO_2Cl)$: [95°]; gives, with PCl_5, ('β')-di-chloro-naphthalene [68°] (Arnell, *Bl.* [2] 39, 62).

Amide $C_{10}H_6Cl(SO_2NH_2)$: [187°] (Cleve, *B.* 20, 73).

(α) - Chloro - naphthalene sulphonic acid $C_{10}H_6Cl.SO_3H$. Formed in small quantity, together with the preceding, by sulphonating chloro-naphthalene with $Cl.SO_3H$ (Armstrong a. Williamson, *C. J. Proc.* 2, 234).

Chloride $C_{10}H_6Cl.SO_2Cl$: [127°]; short thick prisms.

(β) - Chloro - naphthalene sulphonic acid $C_{10}H_6Cl(SO_3H)$. Sparingly sol. water.

Formation.—1. By sulphonation of (β)-chloro-naphthalene by H_2SO_4 or $ClSO_3H$ (Arnell, *Bl.* [2] 45, 184). It appears to be formed by isomeric change from the preceding by heating to 150° (Armstrong a. Wynne, *C. J. Proc.* 3, 22, 145).—2. By the action of cuprous chloride upon diazotised (β)-naphthylamine-sulphonic acid obtained by treatment of (β)-naphthol sulphonic acid with NH_3.

Salts.—BaA'_2.—KA' ½aq.

Chloride $C_{10}H_6Cl(SO_2Cl)$: [110°]; needles; by distillation with PCl_5 it gives (ε)-di-chloro-naphthalene [136°].

Amide $C_{10}H_6Cl(SO_2NH_2)$: [184°]; needles (Forsling, *B.* 20, 80).

(β)-Chloro-naphthalene sulphonic acid $C_{10}H_6Cl.SO_3H$ [2:3']?

Formation.—1. By heating (β)-chloro-naphthalene with fuming H_2SO_4, and separated from the preceding acid through the greater solubility of its lead salt (Arnell, *Bl.* [2] 45, 184).—2. By diazotising (β)-naphthylamine sulphonic acid, and boiling with conc. HCl (Forsling, *B.* 19, 1715).

Properties. — Trimetric scales.—BaA'_2 4aq: laminæ.—KA' aq: small scales.

Chloride [129°]. Converted by PCl_5 into di-chloro-naphthalene [61·5°].

Di-chloro-naphthalene (α)-sulphonic acid $C_{10}H_5Cl_2(SO_3H)$. Prepared by boiling the tetrachloride of (α)-naphthalene-sulphonic chloride with alcoholic KOH (Widmann, *B.* 12, 2228). Long flat needles. M. sol. cold water.

Salts.—A'K 2aq: fine needles.—A'Na aq: long flat prisms.—A'Ag 2aq: white needles.—A'_2Ca 4aq: slightly soluble leaflets.

Chloride [145°]. Scales or needles. Sol. benzene and hot acetic acid. By distillation with PCl_5 it gives (γ)-tri-chloro-naphthalene.

Amide [about 250°]. Flat feathery crystals.

Di-chloro-naphthalene (β)-sulphonic acid $C_{10}H_5Cl_2(SO_3H)$. Prepared by boiling the tetrachloride of naphthalene-(β)-sulphonic chloride ($C_{10}H_7(SO_2Cl)Cl_4$) with alcoholic KOH (Widmann, *B.* 12, 959). Readily sol. hot water, less in cold. Strong acid.

Salts.—A'K 5aq: very fine needles. S. 2·5 at 15°.—A'K 1½aq.—A'K 2½aq: small prisms.—A'Ag aq: crystalline powder.—A'_2Ba 4aq: fine sparingly soluble needles.—A'_2Ca 2aq.

Chloride [133°]; fine white needles. Sol. C_6H_6 and CS_2.

Amide [245°]; fine needles. Insol. water, sol. alcohol.

Tri- and Tetra-chloro-naphthalene sulphonic acids have been described by Laurent (*A.* 72, 299), but not sufficiently characterised.

CHLORO-NAPHTHALIC ACID *v.* CHLORO-OXY-(α)-NAPHTHOQUINONE.

CHLORO - NAPHTHOHYDROQUINONE *v.* CHLORO-HYDRO-NAPHTHOQUINONE.

CHLORO-(α)-NAPHTHOIC ACID

$C_{10}H_6Cl(CO_2H)$, probably  [245°].

Formation.—1. By chlorination of (α)-naphthoic acid in acetic acid solution.—2. By the action of cuprous chloride upon the diazo- compound obtained from nitro-(α)-naphthoic acid [239°].—3. From the nitrile.

Properties.—Sublimes in white needles. By fuming HNO_3 it is converted into chloro-nitro-(α)-naphthoic acid [225°] and chloro-di-nitro-naphthalene [175°] (Ekstrand, *B.* 17, 1604; 18, 2881).

Salt.—A'_2Ca 2aq: needles; S. ·86.

Ethyl ether A'Et: [42°]; quadratic tables.

Amide $C_{10}H_6Cl(CONH_2)$. [239°]. Formed by boiling the nitrile with alcoholic KOH (Ekstrand, *Bn.* ii. 925).

Nitrile $C_{10}H_6Cl.CN$ [145°]. White needles. Formed by chlorination of (α)-naphthonitrile (Ekstrand, *B.* 17, 1604).

Chloro-(β)-naphthoic acid $C_{10}H_6Cl.CO_2H$. [261°]. From the nitrile and fuming HCl at 150° (Ekstrand, *Bn.* ii. 931). Needles (from alcohol).

Ethyl ether EtA'. [45°]. Needles.

Nitrile $C_{10}H_6Cl.CN$. [138°]. From (β)-naphthonitrile in HOAc by chlorinating in presence of iodine.

Di-chloro-(β)-naphthoic acid $C_{10}H_5Cl_2.CO_2H$ [291° uncor.]. Sublimable. Colourless needles. Sparingly soluble in alcohol and in acetic acid. Formed by chlorination of (β)-naphthoic acid.

Salts.—A'_2Ca 2½aq: small sparingly soluble prisms.

Ethyl ether A'Et: [66°]; long needles. S. ·03 (Ekstrand, *B.* 17, 1605).

(α₁α₄) CHLORO-NAPHTHOL $C_{10}H_6Cl(OH)$[1:4]. [57°]. Formed by the action of PCl_5 on (α)-naphthol-sulphonic acid. Small felted needles. On moderate oxidation it gives (α)-naphthoquinone, and by further oxidation phthalic acid (Claus a. Oehler, *B.* 15, 312).

Chloro-(α)-naphthol $C_{10}H_6Cl(OH)$. [109°]. Formed by distilling the compound $C_{10}H_8(HOCl)_2$ with aqueous HCl (Grimaux, *Bl.* [2] 18, 208). Slender needles.

(β)-Chloro-(α)-naphthol $C_{10}H_6Cl(OH)$[2:1] [c. 54°]. Is contained in the mother liquors obtained by passing chlorine into a solution of (α)-naphthol in HOAc (Cleve, *B.* 21, 894).

V. e. sol. most menstrua; only crystallisable from petroleum ether.

Chlorine forms di-chloro-naphthol [106°]. PCl_5 yields tri-chloro-naphthalene [92°].

Chloro-(β)-naphthol, $C_{10}H_6Cl(OH)$[1:2]. [68°] (S.); [70°] (C.). Formed by the action of chlorine on (β)-naphthol sodium suspended in CS_2 (Schall, *B.* 16, 1901), or dissolved in HOAc (Cleve, *B.* 21, 895).

Needles or monoclinic plates (from chloroform); *a*:*b*:*c* = 1·96:1:1·956; β = 66° 54′. Volatile with steam. Converted by PCl_5 into chloronaphthyl phosphate $(C_{10}H_6Cl)_3PO_4$ [152°] or, at a higher temperature, into (1, 2)-di-chloronaphthalene [34°].

(2:3)-Chloro-(β)-naphthol

$C_6H_4\left<\begin{array}{l}CH{:}C(OH)\\ \qquad|\\ CH{:}CCl\end{array}\right.$.

[101° uncor.]. (308°). Formed by heating sodium (β)-naphthol (β)-sulphonate (Rumpf's acid) (1 mol.) with PCl_5 (2 mols.) at 150°–160°. Fine colourless needles. V. e. sol. alcohol, ether, etc., sl. sol. water. Volatile with steam. By further action of PCl_5 it yields di-chloro-naphthalene [61°] (Claus a. Volz, *B.* 18, 3157).

Chloro-(β)-naphthol $C_{10}H_6Cl.OH$. [115° uncor.]. Formed, together with (ε)-di-chloronaphthalene, by heating potassium (β)-naphthol-sulphonate with PCl_5 (3 mols.) to 170° (Claus a. Zimmermann, *B.* 14, 1484). Fine needles or prisms. Sol. alcohol, ether, and hot water. Not volatile with steam.

Di-chloro-(α)-naphthol

$C_6H_4\left<\begin{array}{l}C(OH){:}CCl\\ \qquad\quad|\\ CH\quad{:}CCl\end{array}\right.$.

[101° uncor.]. Formed by heating sodium (α)-naphthol-(β)-sulphonate (1 mol.) with PCl_5 (2–2½ mols.) at 100°–120°. Sublimes in white needles. V. sol. ordinary solvents. By further treatment with PCl_5 it is converted into tri-chloro-naphthalene [90°]. By dilute HNO_3 at 200° it is oxidised to phthalic acid. By boiling with an acetic solution of CrO_3 it is oxidised to di-chloro-(α)-naphthoquinone

$C_6H_4\left<\begin{array}{l}CO.CCl\\ \quad\ \|\\ CO.CCl\end{array}\right.$ [189°].

(Claus a. Knyrim, *B.* 18, 2926).

Di-chloro-(α)-naphthol $C_{10}H_5Cl_2(OH)$ [1:3:4]. [106°] (C.); [108°] (Zincke, *B.* 21, 1027). Formed by passing chlorine into a cold solution of (α)-naphthol in HOAc (Cleve, *B.* 21, 891). Needles. Sol. alcohol, chloroform, benzene. Crystallises from HOAc as $C_{10}H_5Cl_2OH + HOAc$ losing HOAc at 40°–50°.

Reactions.—1. Yields on heating a substance $C_{20}H_{10}Cl_2O_2$ (?).—2. Dilute HNO_3 forms yellow needles of a quinone-like substance and phthalic acid.—3. Oxidation with chromic acid forms chloro-naphthoquinone [116°], which on heating with aniline forms the anilide [208°] (*cf.* Knapp and Schultz, *A.* 210, 189).—4. PCl_5 forms (1,3,4) tri-chloro-naphthalene.

Acetyl derivative $C_{10}H_5Cl_2OAc$. [76°].

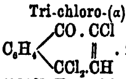
Di-chloro-(β)-naphthol $C_{10}H_5Cl_2(OH)$. [125° uncor.]. Formed, together with tri-chloronaphthalene [90°], by heating sodium (β)-naphthol-(β)-di-sulphonate with PCl_5 at 210°. Colourless felted needles. Sublimable. V. sol. alcohol, ether, etc., sl. sol. hot water (Claus a. Schmidt, *B.* 19, 3174).

Tri-chloro-(α)-naphthol $C_{10}H_4Cl_3(OH)$[4:3:2:1]. [160°]. From tri-chloro-naphthol dichloride and $NaHSO_3$ (Zincke, *B.* 21, 1027). Silky needles (from HOAc). CrO_3 oxidises it to di-chloro-(α)-naphthoquinone.

Acetyl derivative $C_{10}H_4Cl_3OAc$. [124°].

Tri-chloro-(α)-naphthol

$C_6H_4\left<\begin{array}{l}CO.CCl_2\\ \qquad|\\ CCl{:}CH\end{array}\right.$ or



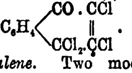
$C_6H_4\left<\begin{array}{l}CO\,.\,CCl\\ \qquad\|\\ CCl_2.CH\end{array}\right.$. *Tri-chloro-(α)-ketonaphthalene.*

[121°]. From (α)-naphthol in HOAc by chlorination (Z.). Flat monoclinic prisms; v. e. sol. benzene. Boiling dilute alcohol converts it into chloro-(α)-naphthoquinone. Hydroxylamine hydrochloride appears to form an **oxim** [c. 148°], a compound $C_{10}H_5Cl_3(NO)$, and a third body [205°].

Tetra-chloro-(α)-naphthol

$C_6H_4\left<\begin{array}{l}CO.CCl_2\\ \qquad|\\ CCl{:}CCl\end{array}\right.$

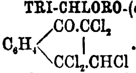
or



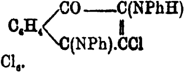
$C_6H_4\left<\begin{array}{l}CO\,.\,CCl\\ \qquad\|\\ CCl_2.CCl\end{array}\right.$. *Tetra-chloro-(α)-ketonaphthalene.* Two modifications, corresponding perhaps to the above formulæ, are formed by chlorinating tri-chloro-(α)-naphthol (Z.), viz. rhombohedra [105°] and prisms [94°]. Boiling dilute alcohol or dilute HOAc convert both into di-chloro-(α)-naphthoquinone. Dilute alcoholic KOH forms chloro-oxy-naphthoquinone. KOH in absolute alcohol appears to form

$C_6H_4\left<\begin{array}{l}CO\ \text{——}\ CO\\ \qquad\qquad|\\ C(OEt){:}CCl\end{array}\right.$. [149°].

TRI-CHLORO-(α)-NAPHTHOL DICHLORIDE



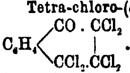
$C_6H_4\left<\begin{array}{l}CO.CCl_2\\ \qquad|\\ CCl_2.CHCl\end{array}\right.$. [157°]. From Cl and (α)-naphthol in cold HOAc (Zincke, *B.* 21, 1027). Monoclinic plates (from benzene). $NaHSO_3$ in presence of HOAc reduces it to tri-chloro-(α)-naphthol. Dilute alcohol or dilute HOAc at 130° form di-chloro-(α)-naphthoquinone. Alcoholic aniline forms



$C_6H_4\left<\begin{array}{l}CO\ \text{——}\ C(NPhH)\\ \qquad\qquad\ \|\\ C(NPh).CCl\end{array}\right.$

[157°] whence $B'_2H_2PtCl_6$.

Tetra-chloro-(α)-naphthol dichloride



$C_6H_4\left<\begin{array}{l}CO\,.\,CCl_2\\ \qquad|\\ CCl_2.CCl_2\end{array}\right.$. [130°]. From tetra-chloro-(α)-naphthol, MnO_2, and HCl (Z.). V. sol. benzene and hot alcohol, sl. sol. ether. Does not react with aniline. May be reduced to tri-chloro-(α)-naphthol. Alcoholic KOH forms $CCl_2{:}CCl.CO.C_6H_4.CO_2H$ [128°].

CHLORO-(α)-NAPHTHOQUINONE $C_{10}H_5ClO_2$ *i.e.*

$C_6H_4\left<\begin{array}{l}CO.CCl\\ \quad\ \|\\ CO.CCl\end{array}\right.$ [111°] (P.); [116°] (Clève, *B.* 21, 891); [118°] (Zincke, *B.* 21, 1027). A by-product in the preparation of di-chloro-(α)-naphthoquinone [189°] by treating di-nitro-(α)-naphthol with $KClO_3$ and HCl (Plagemann, *B.* 15, 485).

The following **amides** are formed by treating di-chloro-(α)-naphthoquinone with the corresponding amine in alcoholic solution (P.):

Methylamide $C_{10}H_4ClO_2NMeH$. [150°]. Orange needles, v. sol. alcohol.

Di-methyl-amide $C_{10}H_4ClO_2NMe_2$. [85°]. Scarlet needles, v. sol. alcohol.

Ethylamide $C_{10}H_4ClO_2NEtH$. [110°]. Brownish-red needles, v. sol. alcohol.

Anilide $C_{10}H_4ClO_2.NHC_6H_5$ [208°] (P.); [202°] (K. a. S.; C.). Red metallic needles. Sol.

acetic acid and alkalis, sl. sol. alcohol. Its *solution in conc. H_2SO_4 is of a magenta colour.* $SnCl_2$ reduces it to a dihydride [170°] (Knapp a. Schultz, *A.* 210, 189).

Nitrosamine $C_{10}H_4ClO_2N(NO)C_6H_5$: [126°]; yellow needles or plates, sol. benzene, sl. sol. ligroïn; formed by passing nitrous acid into the anilide suspended in acetic acid (Plagemann, *B.* 16, 895).

p-Bromo-anilide $C_{10}H_4ClO_2.NHC_6H_4Br$. [262°]. Formed by bromination of chloro-naphthoquinone-anilide; or by the action of *p*-brom-aniline on di-chloro-naphthoquinone. Sol. in NaOH to a red solution, sl. sol. alcohol and acetic acid.

m-Nitro-anilide $C_{10}H_4ClO_2.NHC_6H_4(NO_2)$. [245°]. Formed by the action of *m*-nitraniline on di-chloro-naphthoquinone. Yellowish-red sparingly soluble needles.

p-Nitro-anilide $C_{10}H_4ClO_2.NH.C_6H_4(NO_2)$. [282°]. Formed by the action of *p*-nitraniline on di-chloro-naphthoquinone; or by nitration of chloro-naphthoquinone-anilide. Red felted needles. Sl. sol. alcohol and acetic acid, sol. alkalis to a violet solution. *Nitrosamine* $C_{10}H_4ClO_2N(NO)C_6H_4(NO_2)$. [126°].

o-Toluide $C_{10}H_4ClO_2.NHC_6H_3(CH_3)H$. [152°]. Red metallic crystals. Formed by the action of *o*-toluidine on di-chloro-naphthoquinone.

p-Toluide $C_{10}H_4ClO_2.NHC_6H_4(CH_3)$. [196°]. Formed by the action of *p*-toluidine on di-chloro-naphthoquinone. Metallic red crystals. Sol. acetic acid, sl. sol. alcohol. Dissolves in NaOH to a violet solution.

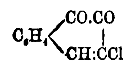
Bromo-o-toluide $C_{10}H_4ClO_2.NHC_6H_3(CH_3)Br$. [212°]. Formed by bromination of chloro-naphthoquinone-*o*-toluide. Sl. sol. alcohol and acetic acid.

Bromo-p-toluide $C_{10}H_4ClO_2.NHC_6H_3(CH_3)Br$. [185°]. Formed by bromination of chloro-naphthoquinone-*p*-toluide. Red needles. Sl. sol. alcohol, dissolves in NaOH to a violet solution.

Nitro-o-toluide $C_{10}H_4ClO_2.NH.C_6H_3(CH_3)(NO_2)$. [230°]. Formed by nitrating the *o*-toluide (P.).

Nitro-p-toluide $C_{10}H_4ClO_2.NHC_6H_3(CH_3)(NO_2)$. [236°-240°]. Formed by nitration of chloro-naphthoquinone-*p*-toluide. Red felted needles. Sl. sol. alcohol and acetic acid. Dissolves in NaOH to a violet solution.

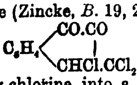
Chloro-(β)-naphthoquinone



$C_6H_4\left\langle\begin{matrix}CO.CO\\ |\\ CH:CCl\end{matrix}\right.$

[172°]. Obtained by passing chlorine gas into (β)-naphthoquinone suspended in ten times its weight of acetic acid. Red needles. Sol. hot alcohol, acetic acid, benzene, and chloroform. Dissolves in dilute caustic alkalis with a reddish-brown colour forming chloro-oxy-(α)-naphthoquinone. With alcoholic NH_3 or aniline it yields respectively the imide or anilide of chloro-oxy-(α)-naphthoquinone (Zincke, *B.* 19, 2497).

Dichloride



$C_6H_4\left\langle\begin{matrix}CO.CO\\ |\\ CHCl.CCl_2\end{matrix}\right.$

[128°]. Formed by passing chlorine into a solution of (β)-naphthoquinone in HOAc (Zincke, *B.* 20, 2890). Thin needles (containing 2aq). In the hydrated condition it melts at 112°. Methylamine forms

$C_6H_4\left\langle\begin{matrix}CO.C(OH)\\ \diagdown\diagdown\\ C(NMe).CCl\end{matrix}\right.$

[200°].

Di-chloro-(α)-naphthoquinone $C_{10}H_4Cl_2O_2$ i.e.

$C_6H_4\left\langle\begin{matrix}CO.CCl\\ \|\\ CO.CCl\end{matrix}\right.$

[189°].

Formation.—1. From chloro-naphthalene tetrachloride $C_{10}H_7Cl_5$ and boiling HNO_3 (Laurent, *A. Ch.* [2] 74, 35; *Rev. Scient.* 13, 591).—2. From di-nitro-naphthol, $KClO_3$ and HCl (Graebe, *A.* 149, 3).—3. From naphthalene in HOAc and CrO_2Cl_2 (Carstanjen, *B.* 2, 633).—4. Together with chlorinated phthalic acids by oxidation of tetra-chloro-naphthalene [140°] (from (α)-naphthol-tri-sulphonic chloride and PCl_5) with CrO_3 or HNO_3.

Properties.—Sublimes in yellow needles. Insol. water, sl. sol. cold alcohol and ether. By alkalis it is converted into chloro-oxy-(α)-naphthoquinone which forms yellow needles [215°]. With aniline it yields $C_{10}H_4Cl(NHPh)O_2$, splendid violet-red crystals [203° uncor.] (Claus a. Mielcke, *B.* 19, 1184). Oxidation gives phthalic acid. PCl_5 forms penta-chloro-naphthalene.

Di-chloride $C_{10}H_4Cl_4O_2$. [117° uncor.]. Formed by heating di-chloro-(α)-naphthoquinone (10 pts.) with HCl of S.G. 1·2 (48 pts.) and MnO_2 (10 pts.) for 10 hours at 230°. Large colourless prisms. Sublimes unaltered. By $SnCl_2$ or other reducing agent it is re-converted into di-chloro-(α)-naphthoquinone (Claus, *B.* 19, 1142).

('β')-Di-chloro-(α)-naphthoquinone $C_{10}H_4Cl_2O_2$ probably

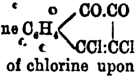
$C_6H_3Cl\left\langle\begin{matrix}CO.CCl\\ \|\\ CO.CH\end{matrix}\right.$

[149° uncor.]. Formed, together with chloro-phthalic acid $C_6H_3Cl(CO_2H)_2$ [4:2:1], by oxidation of (ε)-di-chloro-naphthalene in acetic acid solution by CrO_3. Yellow needles. Sublimable without decomposition. Dissolves in aqueous KOH with a red colour. By boiling with alkalis it is converted into ('β')-chloro-oxy-naphthoquinone $C_{10}H_4Cl(OH)O_2$. (Claus a. Müller, *B.* 18, 3073).

Di-chloro-(α)-naphthoquinone $C_{10}H_4Cl_2O_2$. [153°]. Formed, together with the isomeride [189°] by chlorinating di-nitro-naphthol (P.).

p-Di-chloro-(α)-naphthoquinone $C_{10}H_4Cl_2O_2$. [174°]. Formed, together with di-chloro-phthalide, by oxidation of di-chloro-naphthalene [68°] with CrO_3 and glacial acetic acid. Long yellow needles. Sublimable. Sol. alcohol and ether, nearly insol. water. By NaOH it is converted into chloro-oxy-(α)-naphthoquinone. With aniline it forms $C_{10}H_4Cl(NHPh)O_2$, garnet red needles, [185°] (Guareschi, *B.* 19, 1155).

Di-chloro-(β)-naphthoquinone



$C_6H_4\left\langle\begin{matrix}CO.CO\\ |\\ CCl:CCl\end{matrix}\right.$

[184°]. Formed by the action of chlorine upon (β)-naphthoquinone, or better (α)-amido-(β)-naphthol in acetic acid. Red plates, long flat needles, thick rhombi or monoclinic tables. Sol. chloroform, sl. sol. alcohol. Sublimable. With alcoholic NH_3 or aniline it yields the imide or anilide of chloro-oxy-(α)-naphthoquinone. It dissolves in cold dilute NaOH to a colourless solution forming an acid $C_{10}H_6Cl_2O_3$ which possibly has the constitution  $C_6H_4\left<\begin{array}{l}C(OH).CO_2H\\ CCl.CCl\end{array}\right.$. (Zincke, *B.* 19, 2499). This acid crystallises in slender needles (containing aq) [100°]; it forms a *methyl-ether* $C_{10}H_4Cl_2(OH).CO_2Me$ [138°] and an *acetyl-methyl ether* $C_{10}H_4Cl_2(OAc)CO_2Me$ [76°].

Tri-chloro-(α)-naphthoquinone $C_{10}H_3Cl_3O_2$. Formed by oxidation of tri-chloro-naphthalene [90°] (from (β)-naphthol-(β)-di-sulphonic acid and PCl_5) with CrO_3 and acetic acid. It was not isolated, but by treatment with aniline was converted into the anilide $C_{10}H_4Cl_2(NHPh)O_2$, which formed reddish-violet plates [228°] uncor., sublimable (Claus a. Schmidt, *B.* 19, 3177).

Tetra-chloro-(α)-naphthoquinone  $C_6Cl_4\left<\begin{array}{l}CO.CH\\ \quad\;\|\\ CO.CH\end{array}\right.$ [160° uncor.]. Long yellow needles. Sublimable. Prepared by oxidation of penta-chloro-naphthalene with fuming HNO_3 at 110°. PCl_5 converts it into hepta-chloro-naphthalene (Claus a. Lippe, *B.* 16, 1018).

Penta-chloro-(α)-naphthoquinone  $C_6Cl_4\left<\begin{array}{l}CO.CCl\\ \quad\;\|\\ CO.CH\end{array}\right.$ [217° uncor.]. Formed together with tetra-chloro-phthalic acid, by oxidation of hepta-chloro-naphthalene [194°] with HNO_3 (1·5 S.G.) at 100°. Glistening golden plates (from chloroform). Sublimes in long glistening needles. By alkalis it is converted into salts of tetra-chloro-oxy-naphthoquinone  $C_6Cl_4\left<\begin{array}{l}CO.C(OH)\\ \quad\;\|\\ CO.CH\end{array}\right.$. With aniline it yields  $C_6Cl_4\left<\begin{array}{l}CO.C(NHC_6H_5)\\ \quad\;\|\\ CO.CH\end{array}\right.$, which crystallises from alcohol or acetic acid in glistening red plates [240° uncor.]. By heating with PCl_5 at 250° it is converted into per-chloro-naphthalene [203°] (Claus a. Wenzlik, *B.* 19, 1166).

DI-CHLORO-(β)-NAPHTHOQUINONE DI-CHLORIDE  $C_6H_4\left<\begin{array}{l}CO.CO\\ \quad\;|\\ CCl_2.CCl_2\end{array}\right.$ [91°]. Formed by passing chlorine into a solution of (1, 2)-amido-naphthol in HOAc (Zincke, *B.* 21, 495). Yellowish crystals (from ether); v. sol. ether, HOAc, and petroleum ether.

DI-CHLORO-(α)-NAPHTHOQUINONE SULPHONIC ACID $C_{10}H_3Cl_2O_2(SO_3H)$ [2:3:1:4:3′]. From sodium di-nitro-(α)-naphthol sulphonate ((α)-*naphthol yellow*), $KClO_3$ and HCl (Claus, *J. pr.* [2] 37, 181). Light yellow plates, v. sol. water and alcohol, insol. ether. Converted by potash-fusion into (β)-oxy-phthalic acid. Aniline forms $C_{10}H_3Cl(NPhH)O_2(SO_3H)$ [190°], a colouring matter crystallising in dark-red plates.

Salts.—NaA′: yellow crystalline powder (from water) or yellow plates (from alcohol).—CaA′₂.—BaA′₂.

DI-CHLORO-NAPHTHOSTYRIL *v.* DI-CHLORO-AMIDO-NAPHTHOIC LACTAM.

TETRA-CHLORO-(ββ)-DINAPHTHYL $C_{20}H_{10}Cl_4$. Amorphous (Smith a. Poynting, *C. J.* 27, 854).

Hexa-chloro-(αα)-dinaphthyl $C_{20}H_8Cl_4$. Amorphous (Lossen, *A.* 144, 77).

CHLORO-(α)-NAPHTHYL-AMINE $C_{10}H_8ClN$ *i.e.*  $C_6H_4\left<\begin{array}{l}C(NH_2):CH\\ \qquad\quad|\\ CH{=}CCl\end{array}\right.$ or  $C_6H_4\left<\begin{array}{l}C(NH_2):CCl\\ \qquad\quad|\\ CH{=}CH\end{array}\right.$. [56°]. Obtained by reduction of di-chloro-(α)-naphthylamine [82°] with tin and HCl. Thin white needles. Very unpleasant smell. Sl. sol. hot water. Very volatile with steam. Its salts are decomposed by water.

Salts. — B′HCl aq: silky needles. — $B'HClSnCl_2$: thin glistening plates.—$B'H_2SO_4$aq: slender white needles (Clève, *B.* 20, 450).

Chloro-(α)-naphthylamine $C_{10}H_6Cl(NH_2)$. [86°]. From chloro-nitro-naphthalene by reduction (Atterberg, *B.* 10, 548).—B′HCl.

Chloro-(α)-naphthylamine $C_{10}H_6Cl(NH_2)$. [94°]. Formed by reducing (γ)-di-chloro-nitro-naphthalene (Atterberg, *B.* 9, 1730). Fe_2Cl_6 gives a greyish-green coloration. Displacement of NH_2 by Cl forms (ζ)-di chloro-naphthalene (Atterberg, *B.* 10, 548).—B′HCl aq.—$B'HSnCl_3$.—$B'H_2SO_4$.

Chloro-(α)-naphthylamine $C_{10}H_6Cl(NH_2)$. [98°]. Formed by the slow action of $SnCl_4$ on a solution of (α)-naphthylamine hydrochloride exposed to air (Seidler, *B.* 11, 1201).

Acetyl derivative $C_{10}H_6Cl(NHAc)$. [184°].

(α)-Chloro-(β)-naphthylamine $C_{10}H_6Cl.NH_2$ [1:2]. [59°]. From the acetyl derivative and HCl. Elimination of NH_2 gives (α)-chloro-naphthalene.—B′HCl aq.

Acetyl derivative $C_{10}H_6Cl.NHAc$. [147°]. Formed by passing chlorine into a solution of acetyl (β)-naphthylamine in dilute HOAc (Clève, *B.* 20, 1989).

Di-chloro-(α)-naphthylamine $C_{10}H_5Cl_2(NH_2)$. [101°]. Formed by reducing ('β')-di-chloro-nitro-naphthalene [68°]. Needles (from alcohol). B′HCl.—$B'HSnCl_3$.—$B'_2H_2PtCl_6$ 2aq.—$B'H_2SO_4$.

(η)-Di-chloro-naphthylamine $C_{10}H_5Cl_2(NH_2)$. [94° ?]. Formed by reducing (η)-di-chloro-nitro-naphthalene (Clève, *Bl.* [2] 29, 500).—B′HCl.

Di-chloro-(α)-naphthylamine $C_{10}H_7Cl_2N$ probably  $C_6H_4\left<\begin{array}{l}C(NH_2):CCl\\ \qquad\quad|\\ CH{=}CCl\end{array}\right.$. [82°]. Obtained by saponifying its acetyl derivative, which is formed by passing chlorine (2 mols.) into an acetic acid solution of acetyl-(α)-naphthylamine (1 mol.). Crystalline solid, of disagreeable odour. V. e. sol. alcohol. Volatile with steam. Non-basic. By HNO_3 it is oxidised to phthalic acid. By elimination of the NH_2 group by the diazo-reaction, di-chloro-naphthalene [61°] is formed. By tin and HCl it is reduced to mono-chloro-(α)-naphthylamine [56°].

Acetyl derivative $C_{10}H_5Cl_2.NHAc$: [214°]; long thin white needles; sol. acetic acid, alcohol and chloroform; sublimable (Clève, *B.* 20, 448).

DI-CHLORO-DI-(β)-NAPHTHYL-AMINE $(C_{10}H_6Cl)_2NH$.

Benzoyl derivative $(C_{10}H_6Cl)_2NBz$. [203° uncor.]; small white needles; sol. alcohol, benzene, and chloroform. Formed by the action of PCl_5 on the benzoyl derivative of di-(β)-naphthylamine (Claus a. Richter, *B.* 17, 1590).

DI-CHLORO-NAPHTHYLENE-DIAMINE $C_{10}H_4Cl_2(NH_2)_2$. [205°]. Formed by reduction of di-chloro-di-nitro-naphthalene [253°] by tin, HCl, and HOAc (Alén, *Bl.* [2] 36, 435).

DI-CHLORO-(α)-DINAPHTHYLENE-OXIDE $C_{20}H_{10}Cl_2O$. [151°]. Prepared by the action of PCl_5 on (α)-dinaphthylene-oxide (Knecht a. Unzeitig, *B.* 18, 1725). Sublimes and crystallises in yellow needles. V. sol. benzene and acetic acid, sl. sol. alcohol, ether, and chloroform.

Di-chloro-(β)-dinaphthylene-oxide $C_{20}H_{10}Cl_2O$. [245°]. Prepared by the action of PCl_5 on (β)-dinaphthylene-oxide (K. a. U.). Yellow glistening needles (from benzene).

TRI-CHLORO- (α) and (β) -DI-NAPHTHYL-ETHANE $CCl_3.CH(C_{10}H_7)_2$. Formed together by the action of H_2SO_4 on a mixture of naphthalene and chloral, thus: $CCl_3.CH.O + 2C_{10}H_8 = CCl_3.CH(C_{10}H_7)_2 + H_2O$.

Preparation.—6 pts. of H_2SO_4 mixed with 6 pts. of fuming H_2SO_4 are added to a mixture of 3 pts. of chloral, 8 pts. of naphthalene, and 6 pts. of chloroform (Grabowski, *B.* 11, 298).

(β)-*modification* [156°]. Crystals. Insol. cold, sl. sol. hot, alcohol and ether. Separated from the (α)-modification by its sparing solubility in alcohol. On distillation it loses HCl forming dichloro-(β)-dinaphthyl-ethylene.

Tetra-nitro-derivative [258°]. Yellow powder. Insol. alcohol, ether, C_6H_6, &c.

(α)-*modification.* Not isolated in the pure state. V. sol. alcohol.

DI-CHLORO-(α)-DI-NAPHTHYL-ETHYLENE $CCl_2:CH(C_{10}H_7)_2$. [150°]. Sl. sol. cold, v. sol. hot, alcohol. Long colourless needles. Less stable than the (β)-modification. Prepared by distilling crude trichloro-(α)-di-naphthyl-ethane with 20 p.c. of lime (Grabowski, *B.* 11, 299).

Tetra-nitro-derivative. [214°].

Di-chloro-(β)-di-naphthyl-ethylene $CCl_2:CH(C_{10}H_7)_2$. [219°]. (above 360°). Distils without decomposition. Short prismatic pillars. Sl. sol. alcohol. Prepared by the distillation of tri-chloro-(β)-di-naphthyl-ethane.

Tetra-nitro-derivative. [293°] (Grabowski, *B.* 11, 299).

CHLORO-(β)-NAPHTHYL-PHOSPHORIC ACID $C_{10}H_6Cl.OPO(OH)_2$. [205° uncor.]. Formed as a by-product in the action of PCl_5 (2 mols.) on potassium (β)-naphthol-sulphonate (1 mol.) at 150° (Claus a. Zimmermann, *B.* 14, 1483). Small plates. By boiling alkalis it is decomposed into chloro-(β)-naphthol and phosphate.

CHLORO-NICOTINIC ACID *v.* CHLORO-PYRIDINE-CARBOXYLIC ACID.

ω-DI-CHLORO-o-NITRO-ACETOPHENONE. $C_6H_4(NO_2).CO.CHCl_2$. [73°]. *Nitro-phenyl di-chloro-methyl ketone.* Formed by chlorination of $C_6H_4(NO_2).CO.Me$ (Gevekoht, *A.* 221, 328). Plates (from benzoline).

CHLORO-NITRO-AMIDO-PHENOL $C_6H_5ClN_2O_3$ *i.e.* $C_6H_2Cl(NO_2)(NH_2)(OH)$ [2:4:6:1]. [160°]. Formed by reducing chloro-di-nitro-phenol [110°] with ammonium sulphide (Griess a. Kolbe, *A.* 109, 286; Faust a. Miller, *A.* 173, 315; *Z.* 1871, 339; Armstrong, *C. J.* 25, 14). Slender brass-yellow needles (containing ½ aq) (from hot water). When dried at 100° it is scarlet. Elimination of NH_2 gives chloro-nitro-phenol [110°].—B'HCl: yellowish needles.—$B'_2H_2SO_4$.—$NH_4(C_6H_4ClN_2O_3)$.—$Ba(C_6H_4ClN_2O_3)_2$ 4aq: slender black needles.

Chloro-nitro-amido-phenol. ***Methyl ether*** $C_6H_2(Cl)(NO_2)(OMe)(NH_2)$. *Chloro-nitro-anisidine.* ***Acetyl derivative*** [185°], yellow needles, sol. alcohol and ether, insol. cold water (Herold, *B.* 15, 1686).

Chloro-di-nitro-amido-phenol. ***Methyl ether*** $C_6H(Cl)(NO_2)_2(OMe)(NH_2)$. ***Acetyl derivative*** [165°], yellow needles (H.).

Chloro-tri-nitro-amido-phenol. ***Methyl ether*** $C_6(Cl)(NO_2)_3(OMe)(NH_2)$. ***Acetyl derivative*** [198°], orange-yellow needles (H.).

CHLORO-NITRO-AMIDO-DI-PHENYL-AMINE *v.* CHLORNITROPHENYL-PHENYLENE-DIAMINE.

CHLORO-NITRO-ANILINE $C_6H_3Cl(NO_2)(NH_2)$ [4:3:1]. [103° uncor.].

Formation.—1. By nitration of *p*-chloro-aniline dissolved in 10 pts. of H_2SO_4; the yield is 50 p.c. of the chloraniline.—2. Together with a much larger quantity of the (6:3:1)-isomeride by reduction of chloro-di-nitro-benzene $C_6H_3Cl(NO_2)_2$ [4:3:1] in alcoholic solution with $SnCl_2$ and HCl.

Properties.—Small yellow glistening needles (from hot petroleum-ether), or long thin needles (from boiling water). V. sol. alcohol, ether and chloroform, m. sol. hot water, nearly insol. cold water. Weak base. By elimination of the NH_2 group it gives *o*-chloro-nitro-benzene [33°]. By replacement of the NH_2 group by Cl, di-chloro-nitro-benzene [55°] is formed.

Acetyl derivative $C_6H_3Cl(NO_2)(NHAc)$ [100°]; small yellow needles (Claus a. Stiebel *B.* 20, 1379).

Chloro-nitro-aniline $C_6H_3Cl(NO_2)(NH_2)$ [2:4:1]. [105°]. Prepared by heating (1, 2, 4)-di-chloro-nitro-benzene [43°] with ammonia at 210° (Beilstein a. Kurbatoff, *A.* 182, 98). Appears also to be formed in small quantity by nitrating acetyl-*o*-chloro-aniline. Light yellow needles. Elimination of NH_2 gives *m*-chloro-nitro-benzene.

Acetyl derivative $C_6H_3Cl(NO_2)(NHAc)$. [139°].

Chloro-nitro-aniline $C_6H_3Cl(NO_2)(NH_2)$ [4:2:1]. [115°]. (B. a. K.); [116°] (K.). From (1,4,2)-di-chloro-nitro-benzene and alcoholic NH_3 at 165°. Formed also by nitrating acetyl *p*-chloro-aniline (Körner, *G.* 4, 373; Beilstein a. Kurbatoff, *B.* 9, 633; *A.* 182, 94). Orange-yellow needles (from water) or spherical groups of brick-red needles (from alcohol). Elimination of NH_2 gives *m*-chloro-nitro-benzene. Reduction to chloro-phenylene-diamine followed by treatment with sodium-amalgam gives *o*-phenylene-diamine (Körner).

Chloro-nitro-aniline $C_6H_3Cl(NO_2)(NH_2)$ [6:3:1]. [117°].

Formation.—1. Together with a smaller quantity of the (4:3:1)-isomeride by reduction of chloro-di-nitro-benzene $C_6H_3Cl(NO_2)_2$ [4:3:1] in alcoholic solution with $SnCl_2$ (Claus a. Stiebel, *B.* 20, 1379).—2. By nitration of acetyl-*o*-chloro-aniline (B. a. K.).

Properties.—Yellow needles. Elimination of NH_2 gives *p*-chloro-nitro-benzene.

Acetyl derivative $C_6H_3Cl(NO_2)(NHAc)$. [154°].

Chloro-nitro-aniline $C_6H_3Cl(NO_2)(NH_2)$ [3:6:1]. [125°].

Formation.—1. By heating (3,6,1)-di-chloro-nitro-benzene [33°] with alcoholic NH_3 for 10 hours at 160° (Körner, *G.* 4, 373).—2. From chloro-di-nitro-benzene [89°] and NH_3 (Laubenheimer, *B.* 9, 1826).—3. By nitrating acetyl *m*-chloro-aniline (B. a. K.).

Properties.—Thin yellow laminæ (from alcohol). Elimination of NH_2 gives *p*-chloro-nitro-benzene. Reduction by tin and HCl gives chloro-phenylene-diamine whence sodium-amalgam produces *o*-phenylene-diamine (Körner).

Acetyl derivative $C_6H_3Cl(NO_2)(NHAc)$. [115°].

Chloro-nitro-aniline $C_6H_3Cl(NO_2)(NH_2)$ [3:4:1]. [157°]. Formed, together with the preceding, by nitrating acetyl *m*-chloro-aniline (B. a. K.). Yellow laminæ (from benzene). Elimination of NH_2 gives *o*-chloro-nitro-benzene [32·5°].

Acetyl derivative [142°].

Chloro-di-nitro-aniline $C_6H_2Cl(NO_2)_2(NH_2)$ [4:2:6:1]. [145°]. From di-chloro-di-nitro-benzene [104°] and alcoholic NH_3. Formed also by chlorinating di-nitro-aniline [138°] and by treating the methyl ether of chloro-di-nitro-phenol [65°] with NH_3 (Körner). Orange needles. Alcoholic KOH converts it into chloro-di-nitro-phenol.

Di-chloro-nitro-aniline $C_6H_2Cl_2(NO_2)(NH_2)$ [3:6:2:1]. [68°]. From its acetyl derivative, which is formed, together with the (3,6,4,1)-isomeride [153°], by the nitration of $C_6H_3Cl_2(NHAc)$ [3:6:1] (Beilstein a. Kurbatow, *A.* 192, 232). Also from (3,6,2,1)-di-chloro-di-nitro-benzene and alcoholic NH_3 (Körner). Yellow needles. Displacement of NH_2 by Cl gives (3,6,1,2)-tri-chloro-nitro-benzene [89°].

Acetyl derivative $C_6H_2Cl_2(NO_2)(NHAc)$. [205°].

Di-chloro-nitro-aniline $C_6H_2Cl_2(NO_2)(NH_2)$ [3:5:6:1]. [79°]. Prepared together with the (3,5,4,1)-isomeride [171°] by nitration of acetyl-(1,3,5)-di-chloro-aniline. Yellow needles. Converted by elimination of NH_2 into di-chloro-nitro-benzene [33°].

Acetyl derivative [139°]. Sol. CS_2 (Beilstein a. Kurbatow, *B.* 11, 1979).

Di-chloro-nitro-aniline $C_6H_2Cl_2(NO_2)(NH_2)$ [4:3:2:1]. [96°]. Prepared together with the (4,3,6,1)-isomeride [175°] by nitration of acetyl-(4,3,1)-di-chloro-aniline. Yellow needles.

Acetyl derivative [153°] (Beilstein a. Kurbatow, *B.* 11, 1978).

Di-chloro-*o*-nitro-aniline $C_6H_2Cl_2(NO_2)(NH_2)$ [2:4:6:1]. [99°]. Formed by passing chlorine into a solution of *o*-nitraniline in conc. HCl (Langer, *A.* 215, 111). Formed also by nitration of acetyl-(4,2,1)-di-chloro-aniline, or by chlorination of acetyl-(4,2,1)-chloro-nitro-aniline, and decomposition of the resulting acetyl derivative by HCl (Witt, *B.* 7, 1603; 8, 820). Slender orange needles (from benzoline). V. sol. alcohol, ether, or benzoline. Elimination of NH_2 gives di-chloro-nitro-benzene [65°].

Acetyl derivative $C_6H_2Cl_2(NO_2)(NHAc)$. [188°].

Di-chloro-nitro-aniline $C_6H_2Cl_2(NO_2)(NH_2)$ [3:6:4:1]. [153°]. Prepared, together with the (3,6,2,1)-isomeride [68°], by nitration of acetyl-(3,6,1)-di-chloro-aniline. Yellow needles.

Acetyl derivative [146°] (Beilstein a. Kurbatow, *B.* 11, 1978; *A.* 196, 235).

Di-chloro-nitro-aniline $C_6H_2Cl_2(NO_2)(NH_2)$ [3:2:6:1]. [168°]. Formed by heating $C_6H_2Cl_3(NO_2)$ [56°] with alcoholic NH_3 at 210° (Beilstein a. Kurbatow, *A.* 192, 235). By elimination of NH_2 it gives di-chloro-nitro-benzene [43°].

Di-chloro-nitro-aniline $C_6H_2Cl_2(NO_2)(NH_2)$ [3:5:4:1]. [171°]. Large yellow needles. Prepared, together with the (3,5,6,1)-isomeride [79°], by nitration of acetyl-(5,3,1)-di-chloro-aniline. Elimination of NH_2 gives di-chloro-nitro-benzene [71°].

Acetyl derivative. [222°]. Insol. in CS_2 (Beilstein a. Kurbatow, *A.* 196, 227; *B.* 11, 1979).

Di-chloro-nitro-aniline $C_6H_2Cl_2(NO_2)(NH_2)$ [3:4:6:1]. [175°]. Prepared by the action of alcoholic NH_3 on trichloronitrobenzene [58°] or, together with the (4,3,2,1)-isomeride [96°], by the nitration of acetyl-(4,3,1)-di-chloro-aniline. Yellow needles. Displacement of NH_2 by Cl gives tri-chloro-nitro-benzene [58°].

Acetyl derivative [124°]. Less sol. alcohol than the isomeride (1;4,5;6) (Beilstein a. Kurbatow, *A.* 196, 225; *B.* 11, 1978).

Di-chloro-nitro-aniline $C_6H_2Cl_2(NO_2)(NH_2)$ [2:6:4:1]. [188°]. Formed by chlorination of *p*-nitro-aniline (Körner, *G.* 4, 276; Witt, *B.* 8, 143). Lemon-yellow needles. Elimination of NH_2 gives di-chloro-nitro-benzene [65°].

Acetyl derivative $C_6H_2Cl_2(NO_2)(NHAc)$. [210°].

Di-chloro-di-nitro-aniline $C_6HCl_2(NO_2)_2(NH_2)$ [3:4:2:6:1]. [128°]. Formed by nitrating acetyl-(4,3,1)-di-chloro-aniline, and eliminating Ac by H_2SO_4 (Beilstein a. Kurbatow, *A.* 196, 235; *B.* 11, 1978). Large red needles.

Acetyl derivative $C_6HCl_2(NO_2)_2(NHAc)$ [246°].

Tri-chloro-*m*-nitro-aniline $C_6HCl_3(NO_2)(NH_2)$ [5:4:2:3:1]. [98°]. From *m*-nitraniline (1 pt.), conc. HCl (25 pts.) and water (20 pts.), by passage of a mixture of air and chlorine (Langer, *A.* 215, 110). Long, broad yellow needles (from light petroleum).

Tri-chloro-nitro-aniline $C_6HCl_3(NO_2)(NH_2)$ [2:4:5:6:1]. [124°]. Prepared by nitration of acetyl-tri-chloro-aniline [185°], and elimination of Ac by HCl. Yellow needles.

Acetyl derivative $C_6HCl_3(NO_2)(NHAc)$. [193°] (Beilstein a. Kurbatow, *A.* 196, 235; *B.* 11, 1980).

CHLORO-NITRO-ANISIDINE *v. Methyl ether* of CHLORO-NITRO-AMIDO-PHENOL.

CHLORO-NITRO-ANISOL *v. Methyl ether* of CHLORO-NITRO-PHENOL.

***o*-CHLORO-NITRO-BENZENE** $C_6H_4Cl(NO_2)$ [1:2]. Mol. w. 157½. [32·5°]. (243°). S.G. ^{22} 1·368.

Formation.—1. Together with the *p*-isomeride, by nitrating chloro-benzene (Jungfleisch, *A. Ch.* [4] 15, 186; Laubenheimer, *B.* 7, 1765; 8, 1621; Sokoloff, *Z.* 1866, 621; Lesimple, *Z.* [2] 4, 225). 2. From chloro-nitro-aniline [157°] by elimination of NH_2 through the diazo- reaction (Beilstein a. Kurbatoff, *B.* 9, 633; *A.* 182, 107).—3. In small quantity by the action of PCl_5 on *o*-nitro-phenol (Engelhardt a. Latschinoff, *Z.* [2] 6, 225).

Properties.—Needles; converted by aqueous NaOH at 130° into *o*-nitro-phenol. Not attacked by alcoholic KCy.

***m*-Chloro-nitro-benzene** $C_6H_4Cl(NO_2)$ [1:3]. [45°]. (236° cor.).

Formation.—1. By chlorination of nitro-benzene in presence of iodine (Laubenheimer, *B.* 7, 1765) or $SbCl_3$ (Beilstein a. Kurbatoff, *A.* 182, 102).—2. From *m*-nitro-aniline by displacement of NH_2 by Cl through the diazo- reaction (Griess, *Pr.* 13, 381).

Preparation.—1. From nitro-benzene (500 g.) and Fe_2Cl_6 (10 g.) by chlorination (Varnholt, *J. pr.* [2] 36, 25).—2. By running a solution of $NaNO_2$ into a hot solution of *m*-nitro-aniline and Cu_2Cl_2 in dilute HCl (Sandmeyer, *B.* 17, 2650).

Properties. — Trimetric crystals; *a:b:c* = ·561:1:·498. Sublimes in flat needles. V. sol. ether, benzene, chloroform, CS_2, HOAc, and hot alcohol.

Reactions.—1. *Nitration* forms $C_6H_3Cl(NO_2)_2$ [39°].—2. Alcoholic KOH gives $(C_6H_4Cl)_2N_2O$. [97°].—3. Alcoholic KCy gives *o*-chloro-benzonitrile (Richter, *B.* 8, 1418).

***p*-Chloro-nitro-benzene** $C_6H_4Cl(NO_2)$ [1:4]. [83°]. (242°). S.G. ^{22} 1·38.

Formation.—1. Together with the *o*-isomeride, by nitration of chloro-benzene (Riche, *A.* 121, 357; Jungfleisch, *A. Ch.* [4] 15, 186).—2. From *p*-nitro-aniline by displacement of NH_2 by Cl (Griess, *Pr.* 13, 381).—3. From *p*-nitrophenol and PCl_5 (Engelhardt a. Latschinoff, *Z.* 1870, 230).—4. From (3,6,1)-chloro-nitro-aniline by elimination of NH_2 (Beilstein a. Kurbatoff, *A.* 182, 105).

Properties.—Trimetric plates.

Reactions.—1. Heating with aqueous Na_2CO_3 and NaOH at 130° slowly forms *p*-nitro-phenol. 2. Alcoholic KOH gives $(C_6H_4Cl)_2N_2O$ and, at 180°, $C_6H_4Cl.N_2.C_6H_4Cl$. If the alcohol be dilute $C_6H_4Cl.OEt$ is formed.—3. Alcoholic KCy gives *m*-chloro-benzonitrile.

Chloro-di-nitro-benzene $C_6H_3Cl(NO_2)_2$ [1:3:4?]. Mol. w. 202½. According to Laubenheimer (*B.* 9, 760, 768) the chloro-di-nitro-benzene formed by nitrating *m*-chloro-benzene, exists in four modifications, viz.:

(α). [36°]. Thick monoclinic prisms: *a:b:c* = 1·887:1:·981; β = 114° 14′. Gradually passes into the (γ) modification.

(β). [37°]. Monoclinic prisms, *a:b:c* = ·625:1:·560; β = 91° 27′. Gradually passes into the (γ) modification.

(γ). [39°]. Thin trimetric needles.

(δ). Liquid.

Reactions.—1. Aqueous NaOH forms chloro-nitro-phenol [89°]. — 2. *Aniline* forms $C_6H_3Cl(NO_2)(NPhH)$.—3. *Tin* and HCl reduce it to chloro-phenylene-diamine [72°].—4. Boiled with a solution of sodium sulphite it gives chloro-nitro-benzene-sulphonic acid and $NaNO_2$ (Laubenheimer, *B.* 15, 597).—5. *Phenyl-hydrazine* forms $C_6H_3Cl(NO_2).N_2H_2Ph$ [140°] (Willgerodt, *J. pr.* [2] 37, 355).

Chloro-di-nitro-benzene $C_6H_3Cl(NO_2)_2$ [1:2:4]. [53·5°]. (315°). S.G. ^{18} 1·697.

Formation.—1. By nitration of *o*- or *p*-chloro-nitro-benzene (Jungfleisch, *A. Ch.* [4] 15, 186).—2. From di-nitro-phenol and PCl_5 (Clemm, *Z.* 1870, 274).

Properties.—Trimetric crystals; v. sl. sol. cold alcohol, v. sol. boiling alcohol and ether. Jungfleisch describes a physical isomeride [42°].

Reactions.—1. *Tin* and HCl form chloro-nitro-aniline [89°].—2. Strong aqueous KOH forms di-nitro-phenol.—3. Alcoholic NH_3 at 110° forms di-nitro-aniline [175°].—4. Alcoholic NMe_3 forms $C_6H_3(NO_2)_2(NMe_2)$ [78°].—5. *Di-methyl-aniline* gives $C_6H_3(NO_2)_2(NPhMe)$ [167°] (Leymann, *B.* 15, 1233).—6. By the action of KOH dissolved in an alcohol, it gives the ether of the di-nitro-phenol corresponding to the alcohol used (Willgerodt, *B.* 12, 762).—7. *Phenyl-hydrazine* in the cold forms $C_6H_3(NO_2)_2.N_2H_2Ph$ [120°] crystallising in red plates and converted by boiling HOAc into $C_6H_3(NO)_2.N_2Ph$ [247°] (Willgerodt, *J. pr.* [2] 37, 347, 449).

Chloro-tri-nitro-benzene $C_6H_2Cl(NO_2)_3$. [1:2:4:6]. *Picryl chloride.* Mol. w. 247½. [83°]. From tri-nitro-phenol (picric acid) and PCl_5 (Pisani, *A.* 92, 326; Clemm, *J. pr.* [2] 1, 145; *Z.* [2] 6, 444). Amber-yellow monoclinic tables (from ether) or nearly colourless needles (from alcohol). V. sol. boiling alcohol, sl. sol. ether. Combines with benzene and other aromatic hydrocarbons (Liebermann a. Palm, *B.* 8, 378).

Reactions.—1. *Water* or aqueous Na_2CO_3 converts it into tri-nitro-phenol.—2. *Ammonia* forms tri-nitro-aniline.—3. Alcoholic KOH forms $C_6H_2(NO_2)_3OEt$. — 4. *Ethyl-hydrazine* forms $C_6H_2(NO_2)_3N_2H_2Et$ [200°] (Fischer, *A.* 199, 299).—5. *Phenyl-hydrazine* forms $C_{12}H_7N_5O_6$ [225°] (238°) (Willgerodt, *J. pr.* [2] 37, 357).—6. Alcoholic *di-methyl-amine* gives rise to $C_6H_2(NO_2)_3NMe_2$ [114°] (Van Romburgh, *R. T. C.* 2, 105).

Di-chloro-nitro-benzene $C_6H_3Cl_2(NO_2)$ [1:3:4]. [33°]. Formed by nitrating *m*-di-chloro-benzene (Körner, *G.* 4, 305; *J.* 1875, 323; Beilstein a. Kurbatoff, *A.* 182, 97). Long needles (from alcohol). Converted by alcoholic NH_3 at 210° into $C_6H_3Cl(NH_2)(NO_2)$ [1:3:4] [125°]. Aqueous Na_2CO_3 has no action even at 290°. Alcoholic NaOH readily forms $C_6H_3Cl(OEt)(NO_2)$.

Di-chloro-nitro-benzene $C_6H_3Cl_2(NO_2)$ [1:2:4]. [43°]. From $C_6H_2Cl_2(NO_2)(NH_2)$ [1:2:4:3] and [6:2:4:3] by displacement of NH_2 by H (Beilstein a. Kurbatoff, *A.* 192, 235). Formed also by nitration of *o*-di-chloro-benzene (B. a. K., *A.* 176, 41). Long needles (from alcohol). Converted by alcoholic ammonia at 210° into $C_6H_3Cl(NH_2)(NO_2)$ [105°].

Di-chloro-nitro-benzene $C_6H_3Cl_2(NO_2)$ [1:4:6]. [55°]. (266°). S.G. ^{22} 1·669.

Formation.—1. By passing chlorine into cold nitro-benzene (75 g.) containing Fe_2Cl_6 (11·5 g.) (B. a. K.; Page, *A.* 225, 208).—2. By nitration of *p*-di-chloro-benzene (Jungfleisch).—3. From $C_6H_3Cl(NO_2)(NH_2)$ [4:3:1] by the action of Cu_2Cl_2 upon the diazo- compound (Claus a. Stiebel, *B.* 20, 1381).

Properties.—Triclinic crystals (from CS_2). Volatile with steam. Alcoholic KOH converts it into $C_6H_3(OH)Cl(NO_2)$ [1:4:6] [86°], together with $(C_6H_3Cl_2)_2N_2O$ and di-chloro-aniline [50°] (Laubenheimer, *B.* 7, 1600). By alcoholic NH_3 at 200° it is converted into chloro-nitro-aniline [115°].

Di-chloro-nitro-benzene $C_6H_3Cl_2(NO_2)$ [1:3:5]. [65°]. From the di-chloro-nitro-anilines $C_6H_2(NH_2)Cl_2(NO_2)$ [1:2:4:6] and [1:2:6:4] by eliminating NH_2 (Körner, *G.* 4, 376; Witt, *B.* 7, 1604; *B.* 8, 144) Long thin laminæ (from alcohol). Volatile with steam. Alcoholic NH_3 does not act upon it.

Di-chloro-di-nitro-benzene $C_6H_2Cl_2(NO_2)_2$. [103°]. Formed by nitrating *m*-di-chloro-benzene (Körner, *G.* 4, 305; *J.* 1875, 323). Yellowish prisms. Converted by aqueous KOH into a chloro-di-nitro-phenol.

Di-chloro-di-nitro-benzene $C_6H_2Cl_2(NO_2)_2$ [1:4:2:6]. [87°] (J.); [104°] (Engelhardt a. Latschinoff). (312°). S.G. ^{16} 1·710. Formed, together with the following, by nitrating *p*-di-chloro-benzene (Jungfleisch). Small monoclinic plates. Boiling aqueous Na_2CO_3 converts it into di-chloro-phenol [80°].

Di-chloro-di-nitro-benzene $C_6H_2Cl_2(NO_2)_2$ [1:4:2:3 or 5] [107°] (J.); [101°] (E. a. L.). (318°). S.G. ^{16} 1·695. Formed as above. Monoclinic needles. Boiling aqueous Na_2CO_3 converts it into chloro-di-nitro-phenol [70°]. Alcoholic NH_3 at 160° forms $C_6H_2Cl_2(NH_2)(NO_2)$ [66°] (Körner, *G.* 4, 350).

Tri-chloro-nitro-benzene $C_6H_2Cl_3(NO_2)$ [1:2:4:5]. [57°]. (288°). S.G. ^{22} 1·790. Formed by nitrating $C_6H_3Cl_3$ [1:2:4] (Lesimple, *Bl.* [2] 6, 161; *A.* 137, 123). Sulphur-yellow monoclinic prisms (from CS_2). Converted by NH_3 into $C_6H_2(NH_2)Cl_2(NO_2)$ [1:3:4:6].

Tri-chloro-nitro-benzene $C_6H_2Cl_3(NO_2)$ [1:2:3:4]. [56°]. From *c*-tri-chloro-benzene and fuming HNO_3 (Beilstein a. Kurbatow, *A.* 192, 235). Colourless silky needles (from alcohol). V. sol. ether and CS_2, m. sol. dilute (50 per cent.) acetic acid, sl. sol. alcohol. May be reduced to tri-chloro-aniline [68°]. Alcoholic NH_3 forms $C_6H_2Cl_2(NH_2)(NO_2)$ [1:2:3:4] [163°].

Tri-chloro-nitro-benzene $C_6H_2Cl_3(NO_2)$ [1:3:5:2]. [68°]. From *s*-tri-chloro-benzene and fuming HNO_3 (Beilstein a. Kurbatoff, *A.* 192, 233). Long needles (from alcohol). V. sol. CS_2 and light petroleum. Ammonia at 230° forms $C_6H_2(NH_2)_2Cl(NO_2)$ [1:3:5:2].

Tri-chloro-nitro-benzene $C_6H_2Cl_3(NO_2)$ [1:3:6:2]. [89°]. Formed from $C_6H_2Cl_2(NH_2)(NO_2)$ [3:6:1:2] by diazo-reaction (B. a. K.). Colourless needles (from light petroleum). V. sol. alcohol, less sol. light petroleum.

Tri-chloro-di-nitro-benzene $C_6HCl_3(NO_2)_2$. [103·5°]. (335°). S.G. ^{25} 1·85. Formed by nitration of *u*-tri-chloro-benzene (Jungfleisch). Light yellow six-sided prisms. Insol. cold alcohol, sol. hot alcohol and ether.

Tri-chloro-di-nitro-benzene $C_6HCl_3(NO_2)_2$. [1:3:5:2:4]. [130°]. Formed by nitrating *s*-tri-chloro-benzene (Jackson a. Wing, *Am.* 9, 353). Thick white prisms (from alcohol). Sol. cold alcohol and ether; v. sol. benzene, CS_2, and chloroform.

Tri-chloro-tri-nitro-benzene $C_6Cl_3(NO_2)_3$ [1:3:5:2:4:6]. [187°]. Formed by nitrating the preceding (Jackson a. Wing, *Am.* 9, 354). Thick white needles (from alcohol). V. sl. sol. water, sol. alcohol, v. sol. ether, benzene, and CS_2.

Tetra-chloro-nitro-benzene $C_6H(NO_2)Cl_4$ [1:2:3:4:6]. [22°]. From *u*-tetra-chloro-benzene and fuming HNO_3 (Beilstein a. Kurbatoff, *A.* 192, 238). Colourless needles. V. sol. benzene, CS_2, and hot alcohol.

Tetra-chloro-nitro-benzene $C_6HCl_4(NO_2)$ [1:2:3:4:5]. [64·5°]. From *c*-tetra-chloro-benzene and fuming HNO_3 (Beilstein a. Kurbatoff, *A.* 192, 239). Small needles, sl. sol. alcohol.

Tetra-chloro-nitro-benzene $C_6H(NO_2)Cl_4$ [1:2:3:5:6]. [99°]. (304°). S.G. ^{18} 1·744. From *s*-$C_6H_2Cl_4$ and fuming HNO_3. Some chloranil is also formed, but light petroleum dissolves the $C_6H(NO_2)Cl_4$ only (Beilstein a. Kurbatow, *A.* 192, 236; *cf.* Jungfleisch, *loc. cit.*). Formed also by passing chlorine at 100° into nitro-benzene containing Fe_2Cl_6 (Page, *A.* 225, 208). Needles (from alcohol).

Penta-chloro-nitro-benzene $C_6Cl_5(NO_2)$. [146°]. (328°). S.G. ^{25} 1·718. Formed by heating penta-chloro-benzene with fuming HNO_3 (Jungfleisch). Slender needles (from alcohol) or monoclinic tables (from CS_2). V. sol. boiling alcohol, CS_2, and chloroform.

CHLORO-NITRO-BENZENE-SULPHONIC ACID $C_6H_3(Cl)(NO_2)SO_3H$ [1:4:3]. Formed by boiling (1:3:4)-chloro-di-nitro-benzene with a solution of sodic sulphite.—NaA′ 2aq: glistening prisms or needles, sol. water and alcohol.

Amide [159°]. Plates or needles. Sol. alcohol, sl. sol. water (Laubenheimer, *B.* 15, 597).

***m*-Chlor-nitro-benzene sulphonic acid** $C_6H_3(Cl)(NO_2)(SO_3H)$ [1:3:*x*]. Prepared by sulphonation of *m*-chloro-nitro-benzene. On reduction it gives a chloro-amido-phenyl-mercaptan which does not form anhydro- compounds.

Salts.—A'_2Ba^x: white sparingly soluble needles.—A'_2Pb^x: soluble needles.—A′K: white soluble needles (Allert, *B.* 14, 1434).

(α)-Chloro-nitro-benzene-sulphonic acid $C_6H_3(Cl)(NO_2)SO_3H$ [1:3:?]. Formed together with an isomeric (β)-acid by sulphonation of *m*-chloro-nitro-benzene.

Salts.—A′K: needles or plates, sol. alcohol. A′Na $2\frac{1}{2}$aq: yellow needles.—A'_2Ba 2aq: small brown needles or plates, v. sol. alcohol.—A'_2Sr $\frac{1}{2}$aq: thick brown plates, sol. alcohol (Post a. Meyer, *B.* 14, 1606).

(β)-Chloro-nitro-benzene-sulphonic acid $C_6H_3(Cl)(NO_2)SO_3H$ [1:3:?]. Formed together with the preceding by sulphonation of *m*-chloro-nitro-benzene.

Salts.—A′K $\frac{1}{2}$aq: light yellow prisms.—A'_2Ba $\frac{1}{2}$aq: small yellow needles, insol. alcohol.—A'_2Sr: yellow crystalline powder (Post a. Meyer, *B.* 14, 1606).

***m*-Chloro-nitro-benzene di-sulphonic acid** $C_6H_2(Cl)(NO_2)(SO_3H)_2$ [1:3:?:?]. Prepared by sulphonating *m*-chloro-nitro-benzene with boiling H_2SO_4.—$A''K_2$: pearly scales (Allert, *B.* 14, 1436).

CHLORO-NITRO-BENZOIC ACID $C_6H_3Cl(NO_2)(CO_2H)$ [2:4:1]. [137°]. Formed by oxidising chloro-nitro-toluene [65°] by alkaline $KMnO_4$ (Wachendorff, *A.* 185, 275; Lellmann, *B.* 17, 534).

Chloro-nitro-benzoic acid $C_6H_3Cl(NO_2)(CO_2H)$ [3:2:1]. [137°]. Formed by the action of H_2SO_4 and HNO_3 on the di-chloro-benzoic acid [156°] obtained by direct chlorination of benzoic acid (Claus a. Bücher, *B.* 20, 1624). Either this or the following acid ought to be identical with the isomeride [235°].

Chloro-nitro-benzoic acid $C_6H_3Cl(NO_2)(CO_2H)$ [3:4:1]. [136°]. Obtained by the action of H_2SO_4 and HNO_3 on the di-chloro-benzoic acid [201°] formed by chlorination of benzoic acid (C. a. B.).—BaA'_2 4aq (B. a. K.)

(β)-Chloro-nitro-benzoic acid $C_6H_3Cl(NO_2)(CO_2H)$ [3:6:1]. [138°]. One of th

products of the nitration of *m*-chloro-benzoic acid (Ulrich, *A.* 222, 97).

Salts.—BaA'_2.—CaA'_2aq.—PbA'_2.—KA' 2½aq.

Ethyl ether EtA'. [282°] (Cunze a. Hübner, *A.* 135, 113).

Anilide $C_6H_3Cl(NO_2)(CONPhH)$: [164°]; needles.

Chloro-nitro-benzoic acid $C_6H_3Cl(NO_2)CO_2H$ [4:2:1]. [139°]. From $C_6H_3Cl(NO_2)Me$ [4:2:1] by oxidation with HNO_3 (S.G. 1·1) (Varnholt, *J. pr.* [2] 36, 30). Formed also by saponifying its nitrile with dilute H_2SO_4. Long needles; sl. sol. cold water and CS_2, m. sol. chloroform.

Nitrile $C_6H_3Cl(NO_2)CN$. [98°]. From the corresponding chloro-nitro-aniline by Sandmeyer's reaction (Claus, *J. pr.* [2] 37, 197). Needles, v. sol. ether and alcohol, m. sol. cold water.

Chloro-nitro-benzoic acid $C_6H_3Cl(NO_2)CO_2H$ [1:3:5]. [147°]. From $C_6H_3(NH_2)(NO_2)CO_2H$, conc. HCl, and nitrous acid gas (Hübner, *A.* 222, 89). Small needles. V. sol. alcohol, ether and glacial acetic acid.

Salts.—BaA'_2 4aq.—PbA'_2.

Chloro-nitro-benzoic acid $C_6H_3Cl(NO_2)CO_2H$ [2:5:1]. [164°]. S. ·361 at 15°. Formed by nitration of *o*-chloro-benzoic acid (Wilkens a. Rack, *A.* 222, 195; *cf.* Kekulé, *A.* 117, 153). Formed also by the action of PCl_5 on nitro-*o*-oxy-benzoic acid (Hübner, *Z.* [2] 2, 614). Long thin monoclinic needles (from dilute HCl). V. sol. hot water, sl. sol. cold water, v. e. sol. alcohol, ether and benzene.

Salts. — NH_4A'. — NaA'. — BaA'_2 3aq. — SrA'_2 4½aq.—CaA'_2 2aq.—ZnA'_2 5½aq.—CdA'_2 5aq. —PbA'_2.

Ethyl ether EtA'. [29°].

Nitrile $C_6H_3Cl(NO_2)CN$. [106°]. Formed by nitrating the nitrile of *o*-chloro-benzoic acid (Henry, *B.* 2, 493).

Chloro-nitro-benzoic acid $C_6H_3Cl(NO_2)CO_2H$ [4:3:1]. [180°]. Formed by nitration of *p*-chloro-benzoic acid (Reveill, *A.* 222, 182). Formed also by oxidising the corresponding chloro-nitro-toluene (Hübner, *Z.* [2] 2, 614).

Salts.—BaA'_2 4aq.—CaA'_2 5½aq.—MgA'_2 5aq.

Ethyl ether EtA'. [59°].

Anilide $C_6H_3Cl(NO_2)CO.NPhH$. [131°].

Nitrile $C_6H_3Cl(NO_2)CN$. [101°]. From the corresponding chloro-nitro-aniline by Sandmeyer's reaction with cuprous cyanide (Claus, *J. pr.* [2] 37, 197). Needles, sl. sol. cold water.

Chloro-nitro-benzoic acid $C_6H_3Cl(NO_2)CO_2H$ [3:4:1]. [186°]. From the nitrile by saponification with dilute H_2SO_4 (Claus, *J. pr.* [2] 37, 200). White needles. V. sol. hot water, alcohol, ether, chloroform, sl. sol. cold water, CS_2.—**Salts.**—BaA'_2 2aq. — CaA'_2 2aq. — AgA': needles (from water).

Nitrile $C_6H_3Cl(NO_2)CN$. [87°]. From the corresponding chloro-nitro-aniline by displacement of NH_2 by Cy. Colourless needles, sl. sol. cold, v. sol. hot, water.

(a)-Chloro-nitro-benzoic acid $C_6H_3Cl(NO_2)(CO_2H)$ [3:2:1]. [235°]. From *m*-chloro-benzoic acid and fuming HNO_3. Separated by water from the more soluble (*β*)-isomeride [137°] (Ulrich, *A.* 222, 95). Long thin needles, or six-sided tables. V. sl. sol. water, v. sol. ether.

Salts.—BaA'_2 4aq.—CaA'_2 3aq.

Anilide $C_6H_3Cl(NO_2)(CONPhH)$. [186°].

Chloro-di-nitro-benzoic acid $C_6H_2Cl(NO_2)_2CO_2H$ [2:(3 or)5:3?:1]. [238°]. By nitration of *o*-chloro-benzoic acid (Wilkens a. Rack, *A.* 222, 201). Small colourless needles (from petroleum). V. sol. water, alcohol, ether, or petroleum, sl. sol. benzene.

Di-chloro-nitro-benzoic acid $C_6H_2Cl_2(NO_2)(CO_2H)$ [4:3:x:1]. [160°]. Obtained by nitration of (4,3,1)-di-chloro-benzoic acid [201°], which is formed by direct chlorination of benzoic acid (Claus a. Bücher, *B.* 20, 1621). Small needles. Sol. water.

Di-chloro-nitro-benzoic acid $C_6H_2Cl_2(NO_2)(CO_2H)$ [3:2:x:1]. [215°]. Prepared by nitrating (3,2,1)-di-chloro-benzoic acid [156°], which is got by chlorinating benzoic acid (Claus a. Bücher, *B.* 20, 1621). Sl. sol. boiling water.—BaA'_2 4aq: lens-shaped aggregates of small needles.

Tri-chloro-nitro-benzoic acid $C_6HCl_3(NO_2)(CO_2H)$ [2:4:6:3:1]. [220°]. From $C_6HCl_3(CO_2H)$ [2:4:6:1] by nitration (Beilstein a. Kuhlberg, *A.* 152, 239). Small needles (from water). V. sl. sol. boiling water. —CaA'_2 1½aq.—BaA'_2 2aq: crystalline powder.

Tetra-chloro-nitro-benzoic acid $C_6Cl_4(NO_2)CO_2H$ [5:4:3:2:6:1]. Formed by nitration of tetra-chloro-benzoic acid [5:4:3:2:1], by a mixture of fuming HNO_3 and conc. H_2SO_4. Silvery plates. Sol. water. By tin and HCl it is reduced to tetra-chloro-amido-benzoic acid.

Salts.—A'_2Ba 2½aq: v. sol. water, small colourless needles.—A'_2Ca: easily soluble glistening plates (Tust, *B.* 20, 2441).

CHLORO-NITRO-BENZOIC ALDEHYDE $C_6H_3Cl(NO_2)CHO$ [3:4:1]. [62°]. From [3,4,1]-chloro-nitro-toluene by chlorinating and treating the resulting $C_6H_3Cl(NO_2).CH_2Cl$ with lead or copper nitrate solution (Landsberg, *D. P. J.* 262, 139). White needles (from water).

Di-chloro-*o*-nitro-benzoic aldehyde $C_6H_2Cl_2(NO_2)CHO$. [138°]. Obtained by nitration of di-chloro-benzoic aldehyde with a mixture of HNO_3 and H_2SO_4 (Gnehm, *B.* 17, 753). Pearly plates or needles. By treatment with acetone and NaOH it yields tetra-chloro-indigo.

CHLORO-NITRO-CAMPHOR *v.* CAMPHOR.

α-CHLORO-*p*-NITRO-CINNAMIC ACID $C_6H_4(NO_2).CH:CCl.CO_2H$. [224°]. From α-chloro-*p*-nitro-*β*-oxy-*β*-phenyl-propionic acid and HCl (S.G. 1·1) at 180° (Lipp, *B.* 19, 2646). Prisms (from alcohol).

CHLORO-DI-NITRO-CYMENE $C_6HCl(NO_2)_2(CH_3)(C_3H_7)$ [2:?:?:1:4]. [109°]. Monoclinic prisms. Prepared by nitration of chloro-cymene [214°] (Gerichten, *B.* **11**, 1091).

Chloro-di-nitro-cymene $C_6HCl(NO_2)_2(CH_3)(C_3H_7)$ [3:?:?:1:4]. [101°]. From di-nitro-thymol and PCl_5 (Ladenburg a. Engelbrecht, *B.* 10, 1220). Light yellow prisms.

ω-Di-chloro-nitro-cymene $C_6H_3(CHCl_2)(NO_2)(C_3H_7)$ [1:3:4]. From nitro-cuminic aldehyde $C_6H_3(CHO)(NO_2)(C_3H_7)$ and PCl_5 (Widmann, *B.* 15, 167). Oil.

CHLORO-DI-NITRO-ETHANE $C_2H_3Cl(NO_2)_2$? A liquid formed when ethylidene chloride is *heated in a sealed tube with HNO_3 at 100°* (Lauterbach, *B.* 12, 677).

Tetra-chloro-di-nitro-ethane $C_2Cl_4N_2O_4$. Formed by direct union of tetra-chloro-ethylene with nitric peroxide (Hoch a. Kolbe, *J. pr.* [2] 4, 30). Feathery needles (from alcohol); insol. water. Volatile with steam. Decomposes at 140°. Alcoholic KOH forms long prisms of $C_2Cl_3(NO_2)_2(OK)$.

CHLORO-NITRO-ETHYL-ANILINE $C_8H_9ClN_2O_2$ *i.e.* $C_6H_3Cl(NO_2).NHEt$ [5:2:1]. [84°]. From chloro-di-nitro-benzene and an alcoholic solution of ethyl-aniline (Laubenheimer, *B.* 11, 1156). Golden needles; sl. sol. cold alcohol.

DI-CHLORO-NITRO-ETHYL-BENZENE $C_6H_5.CHCl.CHCl.NO_2$. [30°]? Formed by the union of Cl with $C_6H_5CH:CH.NO_2$ (Priebs, *A.* 225, 344). Usually an oil. Volatile with steam. Aqueous NaOH forms $C_6H_5.CCl:CH.NO_2$.

Di-chloro-nitro-ethyl-benzene $C_6H_2Cl_2(NO_2)Et$ [1:4:*x*:2]. [175°]. Formed by boiling di-chloro-ethyl-benzene with HNO_3 and H_2SO_4 for 50 hours (Istrati, *Bl.* [2] 48, 41). Crystalline plates, sol. hot water. Gives a yellowish-white pp. with Fe_2Cl_6.

Di-chloro-tri-nitro-ethyl-benzene $C_6Cl_2(NO_2)_3Et$. [195°]. Formed at the same time as the preceding (Istrati). Groups of small crystals; insol. water, v. sol. alcohol. Fe_2Cl_6 pps. its alcoholic solution.

Tetra-chloro-nitro-ethyl-benzene $C_6Cl_4(NO_2)(C_2H_5)$ [1:3:4:5:2:6]. [30°]. Formed by passing C_2H_4 into a mixture of Al_2Cl_6 and $C_6HCl_4(NO_2)$ (Istrati, *A. Ch.* [6] 6, 498). Gelatinous solid, v. sol. ether and $CHCl_3$. Decomposes on distillation, giving tetra-chloro-di-ethyl-benzene.

TRI-CHLORO-NITRO-ETHYLENE $C_2Cl_3NO_2$(?) Formed by adding C_2Cl_4 to a cooled mixture of H_2SO_4 and fuming HNO_3 (Hoch, *J. pr.* [2] 6, 95). Pungent yellow oil; decomposed by water and alkalis. Br at 150° converts it into $C_2Cl_3Br_2(NO_2)$ [c. 120°]. Liquid nitric peroxide at 115° forms feathery crystals of an unstable compound $C_2Cl_3(NO_2)_3$.

CHLORO-NITRO-MESITYLENE $C_9H_{10}ClNO_2$ *i.e.* $C_6HCl(NO_2)Me_3$ [2:4:1:3:5]. [57°]. Formed by nitrating chloro-mesitylene (Fittig a. Hoogewerff, *A.* 150, 324; *Z.* [2] 5, 168). Pale yellow spicular crystals, v. sol. alcohol.

Chloro-di-nitro-mesitylene $C_6Cl(NO_2)_2Me_3$. [179°]. The chief product of the action of fuming HNO_3 on chloro-mesitylene (F. a. H.). Long colourless needles (from alcohol). Sl. sol. cold alcohol. May be sublimed.

CHLORO-NITRO-METHANE $CH_2Cl(NO_2)$. (123°). S.G. ^{15} 1·466. Formed by the action of chlorine-water on sodium nitro-methane: $CH_2Na(NO_2) + Cl_2 = NaCl + CH_2Cl(NO_2)$. The presence of Cl and the chlorous nitroxyl (NO_2) render the hydrogen displaceable by sodium: hence the liquid dissolves in alkali.

Chloro-di-nitro-methane $CClH(NO_2)_2$.

Potassium salt $CKCl(NO_2)_2$: large yellow crystals, sol. water, explodes at 145° (Losanitsch, *B.* 17, 849).

Di-chloro-di-nitro-methane $CCl_2(NO_2)_2$. (above 100°). S.G. ^{15} 1·685 (M.). Formed by passing chlorine into an aqueous solution of $CKCl(NO_2)_2$ (Losanitsch, *B.* 17, 848).

Preparation.—*Crude naphthalene tetrachloride (200 grms.) is treated with fuming HNO_3 (400 c.c.) in a large retort*; when the reaction is over, the mixture is distilled as long as the residue in the retort froths strongly. The distillate is diluted with twice its bulk of water and the di-chloro-di-nitro-methane distilled off with steam; the yield is 4 p.c. of the naphthalene tetrachloride (Marignac, *A.* 88, 16; Raschig, *B.* 18, 3326).

Properties.—Pungent oil: volatile with steam. On reduction with $SnCl_2$ it yields hydroxylamine.

Tri-chloro-nitro-methane $CCl_3(NO_2)$. *Chloropicrin. Nitro-chloroform.* Mol. w. 164½. (112° cor.). S.G. $\frac{0}{4}$ 1·6923 (Thorpe). C.E. (0°-10°) ·001106; (0°-100°) ·0012256. S. (alcohol of 80·5 p.c.) ·743 (Cossa, *G.* 2, 181). S.V. 110·49. μ, 1·4679 (Gladstone, *C. J.* 23, 101).

Formation.—1. By distilling picric acid and other nitro- compounds with bleaching-powder (Stenhouse, *A.* 66, 241; *P. M.* [3] 33, 53; Gerhardt a. Cahours, *Compt. chim.* 1849, 34, 170).—2. By distilling chloral with conc. HNO_3 (Kekulé, *A.* 106, 144).—3. From chloroform and HNO_3 (Mills, *C. J.* 24, 641).—4. By distilling alcohol with sodic chloride, KNO_3 and H_2SO_4 (Kekulé, *A.* 101, 212).

Preparation.—A saturated (at 30°) solution of picric acid (1 pt.) is mixed with bleaching powder (10 pts.) previously made into paste with water, and the mixture distilled (Hofmann, *A.* 139, 111).

Properties.—Pungent liquid. V. sl. sol. water, v. sol. alcohol and ether.

Reactions.—1. May be *reduced* by iron and acetic acid to methylamine (Geisse, *A.* 109, 282). 2. Fuming HI at 100° forms NH_3, HCl, and CO_2 (Mills, *C. J.* 17, 153).—3. NaOEt in absolute alcohol gives orthocarbonic ether $C(OEt)_4$ (Bassett, *C. J.* 17, 198).—4. KCy and dilute alcohol forms chloro-nitro-malonitrile $C(NO_2)ClCy_2$, an unstable compound which gives with aqueous lead acetate a pp. $C(NO_2)ClCy_2 3PbO$ and with silver nitrate $(C(NO_2)ClCy_2)_3(AgNO_3)_4 8aq$ (Bassett, *C. J.* 19, 352).—5. Alcoholic *ammonia* forms guanidine $C(NH)(NH_2)_2$ (Hofmann, *C. J.* 19, 249).—6. Alcoholic KOH gives KCl and KNO_2 (S.).—7. Alcoholic KOAc at 100° gives KCl, K_2CO_3, and KNO_2 (Bassett, *C. J.* 18, 31).—8. K_2SO_3 forms $CH(NO_2)(SO_3K)_2$ (Rathke, *A.* 161, 149).—9. With benzene in presence of Al_2Cl_6 it yields tri-phenyl-carbinol and tri-phenyl-methane (Elbs, *B.* 16, 1274).—10. With phenol and Al_2Cl_6 the chief product is aurin (tri-oxy-tri-phenyl-carbinol) (E.).—11. With naphthalene and Al_2Cl_6 it yields tri-naphthyl-carbinol (E.).

DI-CHLORO-NITRO-TETRA-METHYL-DI-AMIDO-TRI-PHENYL-METHANE $C_{23}H_{23}N_3Cl_2O_2$ *i.e.* $C_6H_4(NO_2).CH(C_6H_3Cl.NMe_2)_2$. [208°]. From *m*-chloro-di-methyl-aniline, *p*-nitro-benzoic aldehyde, $ZnCl_2$, and HCl (Kock, *B.* 20, 1562). Lemon-yellow scales (from benzene). May be reduced to $C_{23}H_{25}N_3Cl_2$ [181°].

Picrate $C_{35}H_{29}N_9O_{16}Cl_2$. [189°].

CHLORO-NITRO-DI-METHYL-ANILINE $C_6H_3Cl(NO_2)(NMe_2)$ [4:3:1]. [56°]. Formed together with other products by the action of nitrous acid upon *p*-chloro-di-methyl aniline (Koch, *B.* 20, 2459; *cf.* Heidlberg, *B.* 20, 149).

CHLORO-NITRO-NAPHTHALENE $C_{10}H_6Cl(NO_2)$ [1:4]. [85°]. From (α)-chloro-naphthalene and cold HNO_3 (S.G. 1·4). Extremely slender, light yellow concentric needles. PCl_5 gives ('β')-di-chloro naphthalene. Tin and HCl reduce it to (α)-naphthylamine (Atterberg, *B.* 9, 927).

('α')-Chloro-di-nitro-naphthalene $C_{10}H_5Cl(NO_2)_2$ [1:4:1']. [106°]. Formed, together with the foregoing by treating (α)-chloro-naphthalene with warm HNO_3 (S.G. 1·4) (A.; Faust a. Saame, *A.* 160, 68). Long yellow pliable needles, v. sol. hot alcohol. PCl_5 converts it into (δ)-tri-chloro-naphthalene.

('β')-Chloro-di-nitro-naphthalene probably 
. [180°] (A.); [175°] (E.). Obtained by the action of hot fuming HNO_3 on (α)-chloro-naphthalene (Atterberg). Formed by the action of HNO_3 upon chloro-nitro-(α)-naphthoic acid [225°] (Ekstrand, *B.* 18, 2881). Glistening yellow needles (from alcohol). Sl. sol. boiling alcohol.

('β')-Di-chloro-nitro-naphthalene $C_{10}H_5Cl_2(NO_2)$ [1:4:1']. [92°]. From ('β')-di-chloro-naphthalene and HNO_3 (S.G. 1·45) (Widmann, *Bl.* [2] 28, 509). With PCl_5 it gives (δ)-tri-chloro-naphthalene.

Di-chloro-nitro-naphthalene $C_{10}H_5Cl_2(NO_2)$. [95° ?]. Formed, together with an isomeride [142°], by the action of cold conc. HNO_3 on (δ)-di-chloro-naphthalene (Alén, *Bl.* [2] 36, 433).

Di-chloro-nitro-naphthalene $C_{10}H_5Cl_2(NO_2)$. [c. 114°]. From (ε)-di-chloro-naphthalene and cold fuming HNO_3 (Alén, *Bl.* [2] 36, 435). Yellowish needles.

(η)-Di-chloro-nitro-naphthalene $C_{10}H_5Cl_2(NO_2)$. [119°]. Formed by adding fuming HNO_3 to a solution of (γ)-di-chloro-naphthalene in HOAc (Clève, *Bl.* [2] 29, 499). Golden-yellow needles; m. sol. boiling alcohol. PCl_5 forms (ε)-tri-chloro-naphthalene.

Di-chloro-nitro-naphthalene $C_{10}H_5Cl_2(NO_2)$. [139°]. Formed, together with the isomeride [114°], by treating (ε)-di-chloro-naphthalene with cold fuming HNO_3 (Alén, *Bl.* [2] 36, 435). Needles, turning brownish-violet in the air.

Di-chloro-nitro-naphthalene $C_{10}H_5Cl_2(NO_2)$. [142°]. From (δ)-di-chloro-naphthalene and cold conc. HNO_3 (Alén, *Bl.* [2] 36, 433). Needles, turning green in the air.

(γ)-Di-chloro-nitro-naphthalene $C_{10}H_5Cl_2(NO_2)$. [142°]. From (γ)-di-chloro-naphthalene and cold HNO_3 (S.G. 1·4) (Atterberg, *B.* 9, 928). Short sulphur-yellow brittle prisms (from HOAc). PCl_5 gives (δ)-tri-chloro-naphthalene.

('β')-Di-chloro-di-nitro-naphthalene $C_{10}H_4Cl_2(NO_2)_2$. [158°]. Formed by adding HNO_3 (S.G. 1·48) to a solution of ('β')-di-chloro-naphthalene in HOAc (Widmann, *Bl.* [2] 28, 510). Long yellow needles: sl. sol. alcohol.

(γ)-Di-chloro-di-nitro-naphthalene $C_{10}H_4Cl_2(NO_2)_2$. [246°]. From (γ)-di-chloro-nitro-naphthalene [142°] and HNO_3 mixed with H_2SO_4 (Atterberg, *B.* 9, 1730). Light yellow brittle prismatic needles; v. sl. sol. all solvents. PCl_5 gives (ε)-tetra-chloro-naphthalene.

(δ)-Di-chloro-di-nitro-naphthalene $C_{10}H_4Cl_2(NO_2)_2$. [246°]. Formed by adding fuming HNO_3 to a solution of (δ)-di-chloro-naphthalene in HOAc (Alén, *Bl.* [2] 36, 434). Pale yellow prisms, turning green in air.

(ε)-Di-chloro-di-nitro-naphthalene $C_{10}H_4Cl_2(NO_2)_2$. [253°]. Formed by acting on (ε)-di-chloro-naphthalene dissolved in glacial acetic acid with fuming HNO_3 (Alén, *Bl.* [2] 36, 435; Claus a. Dehne, *B.* 15, 320). Pale yellow needles, turning red in air. PCl_5 gives (ζ)-tri-chloro-naphthalene. Alcoholic KOH forms $C_{10}H_4(OEt)_2(NO_2)_2$.

Di-chloro-tri-nitro-naphthalene $C_{10}H_3Cl_2(NO_2)_3$. [178°]. From ('α')-di-chloro-naphthalene, H_2SO_4, and HNO_3 (S.G. 1·48) (Widmann, *Bl.* [2] 28, 505). Brittle yellow prisms (from HOAc); sl. sol. alcohol, v. sol. chloroform.

(ε)-Di-chloro-tri-nitro-naphthalene $C_{10}H_3Cl_2(NO_2)_3$. [200°]. Formed by boiling (ε)-di-chloro-naphthalene with fuming HNO_3 (Alén, *Bl.* [2] 36, 435). Pale yellow needles. PCl_5 gives (η)-tetra-chloro-naphthalene [160°].

Di-chloro-tri-nitro-naphthalene $C_{10}H_3Cl_2(NO_2)_3$. [201°]. Formed by acting on (δ)-di-chloro-naphthalene with fuming HNO_3 at 100° (Alén, *Bl.* [2] 36, 434). Pale yellow needles, turning greenish in the air.

Tetra-chloro-nitro-naphthalene $C_{10}H_3Cl_4(NO_2)$. [155°]. From (δ)-tetra-chloro-naphthalene and conc. HNO_3 (Atterberg a. Widmann, *B.* 10, 1841). Large pale-yellow trimetric prisms (from alcohol-toluene). PCl_5 gives ('β')-penta-chloro-naphthalene.

CHLORO-NITRO-(α)-NAPHTHOIC ACID $C_{10}H_5Cl(NO_2)(CO_2H)$ probably 
. [225°]. Formed by nitration of chloro-(α)-naphthoic acid [245°]. Prismatic needles.

Ethyl ether A'Et: [121°]; tables (from alcohol) (Ekstrand, *B.* 18, 2881).

TRI-CHLORO-TETRA-NITRO-DI-(β)-NAPHTHYL-ETHANE $C_{22}H_{11}(NO_2)_4Cl_3$. [258°]. From tri-chloro-di-(β)-naphthyl-ethane $(C_{10}H_7)_2CH.CCl_3$ and HNO_3 (Grabowski, *B.* 11, 298). Crystalline powder, insol. alcohol, ether, and HOAc.

DI-CHLORO-TETRA-NITRO-DI-(α)-NAPHTHYL-ETHYLENE $C_{22}H_{10}(NO_2)_4Cl_2$. [214°]. From di-chloro-di-(α)-naphthyl-ethylene $(C_{10}H_7)_2C:CCl_2$ and fuming HNO_3 (Grabowski, *B.* 11, 299).

Di-chloro-tetra-nitro-di-(β)-naphthyl-ethylene $C_{22}H_{10}(NO_2)_4Cl_2$. [293°]. Formed by nitrating di-chloro-di-(β)-naphthyl-ethylene (G.).

CHLORO-NITRO-o-OXY-BENZOIC ACID $C_6H_2(Cl)(NO_2)(OH)CO_2H$ [5:?:2:1]. [163°]. Prepared by nitration of *m*-chloro-salicylic acid (Smith a. Peirce, *B.* 13, 34; *Am.* 1, 176). Short needles.

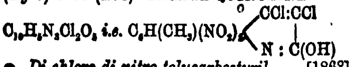
Salts.—A'K: soluble yellow needles.—A'_2Ba: sparingly soluble orange needles.—A'Ag: insol. pp.

Ethyl ether A'Et: [89°]; colourless flat needles.

Amide [199°]. Sl. sol. water, v. sol. alcohol.

Chloro-di-nitro-o-oxy-benzoic acid $C_6HCl(NO_2)_2(OH).CO_2H$. [78°]. From chloro-salicylic acid and fuming HNO_3 (Hasse, *B.* 10, 2191). Long yellow needles (from water).

(*Py.* 1:2)-DI-CHLORO-(*B.* 1:3or4)-DI-NITRO-(*Py.* 3)-OXY-(*B.* 2)-METHYL-QUINOLINE



$C_{10}H_5N_3Cl_2O_5$ *i.e.* $C_6H(CH_3)(NO_2)_2\left\langle\begin{matrix}CCl:CCl\\ |\\ N:C(OH)\end{matrix}\right.$

Di-chloro-di-nitro-tolucarbostyril. [186°]. Formed by nitration of (*Py.* 1:2:3)-di-chloro-oxy-(*B.* 2)-methyl-quinoline in cold H_2SO_4 solution by means of N_2O_3. Long yellow needles with greenish reflex (Rügheimer a. Hoffmann, *B.* 18, 2982).

β-CHLORO-o-NITRO-α-OXY-β-PHENYL-PROPIONIC ACID $C_9H_8ClNO_5$ *i.e.* $[2:1]C_6H_4(NO_2).CHCl.CH(OH).CO_2H$. [126°]. From *o*-nitro-α-oxy-cinnamic acid and fuming HCl (Lipp, *B.* 19, 2649). Needles (from ether-ligroïn). Alcoholic KOH re-converts it into *o*-nitro-α-oxy-cinnamic acid.

β-Chloro-*p*-nitro-α-oxy-β-phenyl-propionic acid $[4:1]C_6H_4(NO_2).CHCl.CH(OH).CO_2H$. [168°]. From *p*-nitro-α-oxy-cinnamic acid and fuming HCl (L.). Small glittering needles; sl. sol. cold water. The Ba salt is split up by boiling water into CO_2, $BaCl_2$, and *p*-nitro-phenyl-acetic aldehyde. Alcoholic KOH gives *p*-nitro-α-oxy-cinnamic acid.

α-Chloro-*o*-nitro-β-oxy-β-phenyl-propionic acid $[2:1]C_6H_4(NO_2).CH(OH).CHCl.CO_2H$. [120°]. Formed by passing chlorine into a solution of *o*-nitro-cinnamic acid in dilute aqueous NaOH (Baeyer, *B.* 13, 2261). Crystalline mass (from benzene-ligroïn). Sol. ether. Converted by NaOH and $FeSO_4$ into indole. Alcoholic KOH gives *o*-nitro-β-oxy-cinnamic acid.

α-Chloro-*p*-nitro-β-oxy-phenyl-propionic acid $[4:1]C_6H_4(NO_2).CH(OH).CHCl.CO_2H$. [165°]. Prepared in the same way from *p*-nitro-cinnamic acid (Beilstein a. Kuhlberg, *A.* 163, 142). Trimetric plates (from water). HCl (S.G. 1·1) at 150° gives chloro-nitro-cinnamic acid. Na_2CO_3Aq gives, on warming, *p*-nitro-β-oxy-cinnamic acid.

CHLORO-o-NITRO-PHENOL $C_6H_4ClNO_3$ *i.e.* $C_6H_3Cl(NO_2)(OH)$ [3:6:1]. Mol. w. 173½. [39°] (L.). [40° and 82½°] (U.).

Formation.—1. By boiling (3,6,1)-chloro-di-nitro-benzene with aqueous NaOH (Laubenheimer, *B.* 9, 768).—2. By nitrating *m*-chloro-phenol (Uhlemann, *B.* 11, 1161).

Properties.—Lemon-yellow needles or prisms (from water).

Salts.—$C_6H_3Cl(NO_2)(ONa)$: scarlet prisms, m. sol. cold water.—BaA'_2 aq: slender scarlet needles.—AgA'.

Methyl ether $C_6H_3Cl(NO_2)(OMe)$. [70·5°]. Needles.

Chloro-*o*-nitro-phenol $C_6H_3Cl(NO_2)(OH)$ [6:2:1]. [70°]. Formed, together with the isomeride [111°], by treating *o*-chloro-phenol with nitric acid (S.G. 1·36) diluted with an equal weight of water (Faust a. Müller, *A.* 173, 309). Flat yellow needles (from chloroform). Volatile with steam. HNO_3 gives chloro-di-nitro-phenol [111°].

Salts.—$C_6H_3Cl(NO_2)(OK)$: long dark-red needles, v. sol. water.—CaA'_2 aq: reddish-brown prisms, m. sol. water.—BaA'_2 aq: short copper-brown plates, sl. sol. water.—AgA': carmine-red scales, sl. sol. water.

Chloro-*o*-nitro-phenol $C_6H_3Cl(NO_2)(OH)$ [4:2:1]. [87°].

Formation.—1. The sole product of the action of dilute HNO_3 on *p*-chloro-phenol (Faust, *B.* 6, 132; *A.* 173, 317; *Suppl.* 7, 190; *Z.* [2] 5, 450). 2. By chlorination of *o*-nitro-phenol (Armstrong a. Prevost, *B.* 7, 922).—3. One of the products of the action of alcoholic KOH on (4,2,1)-chloro-di-nitro-benzene (Laubenheimer, *B.* 7, 1601).

Properties.—Light yellow monoclinic prisms (from $CHCl_3$). V. sl. sol. water, m. sol. alcohol. Volatile with steam. Br and water at 100° give chloro-bromo-nitro-phenol [125°] (Ling, *C. J.* 51, 786). But Br in HOAc gives an isomeric chloro-bromo-nitro-phenol [120°].

Salts.—$C_6H_3Cl(NO_2)(ONH_4)$: orange-red needles.—NaA' aq: red prisms.—BaA'_2 4aq: short red prisms.—AgA'.

Ethyl ether $C_6H_3Cl(NO_2)(OEt)$. [62°]. From AgA' and EtI. Formed also by nitrating the ethyl ether of *p*-chloro-phenol (Hallock, *Am.* 2, 258; *B.* 14, 37).

Chloro-*p*-nitro-phenol $C_6H_3Cl(NO_2)(OH)$ [2:4:1]. [111°].

Formation.—1. By chlorinating *p*-nitro-phenol (Armstrong, *C. J.* 25, 12; Faust a. Müller, *A.* 173, 309; Kollrepp, *A.* 234, 4).—2. Together with the isomeride [70°], by treating *o*-chloro-phenol with dilute HNO_3 (F. a. M.).—3. From chloro-di-nitro-phenol [111°] by reduction to chloro-nitro-amido-phenol followed by displacement of NH_2 by Cl through the diazo- reaction (Faust, *Z.* 1871, 339).

Properties.—White silky needles, m. sol. boiling water, v. sol. alcohol, ether, and chloroform. Very slightly volatile with steam. HNO_3 converts it into chloro-di-nitro-phenol [111°].

Salts.—$C_6H_3Cl(NO_2)(OK)$aq: brown needles, v. sol. water.—CaA'_2 4aq: tufts of canary-yellow needles, v. sol. water.—BaA'_2 7aq: long dark-yellow needles.—AgA': copper-brown flattened needles, sl. sol. water.

Methyl ether $C_6H_3Cl(NO_2)(OMe)$. From the methyl ether of nitro-*o*-amido-phenol by displacement of NH_2 by Cl. Needles.

Ethyl ether $C_6H_3Cl(NO_2)(OEt)$. *Chloro-nitro-phenetol.* [78°]. Formed by chlorinating the ethyl ether of *p*-nitro-phenol by HCl and $KClO_3$ (Hallock, *B.* 14, 37; *Am.* 3, 21).

Chloro-nitro-phenol. *Methyl ether* $C_6H_3Cl(NO_2)(OMe)$ [2:x:1]. *Chloro-nitro-anisol.* [94°]. Prepared by nitration of the methyl ether of *o*-chloro-phenol (Fischli, *B.* 11, 1461). Colourless spikes.

Chloro-di-nitro-phenol $C_6H_2Cl(NO_2)_2(OH)$ [4:2:6:1]. [81°].

Formation.—1. From *p*-chloro-phenol and HNO_3 (S.G. 1·4) (Dubois, *Z.* 1867, 205).—2. By nitration of *p*-chloro-phenol sulphonic acid (Petersen a. Praderi, *A.* 157, 156).—3. By nitrating chloro-nitro-phenol [87°] (Faust a. Saame).—4. From di-chloro-di-nitro-benzene [104°] and boiling aqueous NaOH (Engelhardt a. Latschinoff, *Z.* 1870, 234; Körner, *G.* 4, 395).—5. By chlorinating ('β')-di-nitro-phenol (Armstrong, *B.* 6, 649).—6. In small quantity, together with the isomeride [111°], by the action of ICl on tri-nitro-phenol (picric acid) (Petersen, *B.* 6, 869; Armstrong, *loc. cit.*).—7. By boiling chloro-di-nitro-aniline [145°] with aqueous KOH (Körner).—8. By dissolving chloro-*o*-oxy-benzoic acid in fuming HNO_3 (Smith a. Peirce, *A. Ph. S.* 17, 707; *Am.* 1, 176; *B.* 18, 35).

Properties.—Yellow monoclinic prisms (from chloroform). Sl. sol. hot water, v. sol. alcohol. Combines with aniline, forming $C_6H_3ClN_2O_5NH_2C_6H_5$ [137°] (S. a. P.); decomposed by boiling water.

Salts.—$C_6H_2Cl(NO_2)_2(OK)$: long red needles with green lustre; v. sol. hot, v. sl. sol. cold water.—NH_4A': deep orange needles.—NaA′3aq: scarlet moss-like forms.—BaA'_2aq: pale, saffron-yellow needles, v. sl. sol. hot water.—CuA'_2 2aq: saffron-yellow needles.—PbA'_2aq: yellow needles. AgA′: red needles.

Methyl ether $C_6H_2Cl(NO_2)$ (OMe): [65°].

Ethyl ether $C_6H_2Cl(NO_2)_2(OEt)$: [55°].

Chloro-di-nitro-phenol $C_6H_2Cl(NO_2)_2(OH)$. [80°]. Formed, together with the preceding, with which it is perhaps identical, by nitrating chloro-*o*-oxy-benzoic acid (Smith a. Peirce, *A. Ph. S.* 17, 707). Solidifies at 25°, whereas the preceding solidifies at 69°.—KA′ 1½aq: orange needles, much more soluble in water than the K salt of the preceding.—AgA′: bronzed needles.

Chloro-di-nitro-phenol $C_6H_2Cl(NO_2)_2(OH)$ [2:4:6:1]. [111°] (F. a. S.); [96°] (Zehenter, *M.* 6, 527). S. ·052 at 10°.

Formation.—1. From *o*-chloro-phenol and conc. HNO_3 (Griess, *A.* 109, 286; Armstrong, *C. J.* 25, 96; Faust a. Müller, *A.* 173, 312).—2. From *o*- or *p*-nitro-phenol by successive chlorination and nitration (Faust a. Saame, *A. Suppl.* 7, 195; Seifart, *A. Suppl.* 7, 198).—3. The chief product of the action of ICl on picric acid (Petersen, *B.* 6, 368).—4. By chlorinating di-nitro-phenol [114°] (Armstrong, *C. J.* 25, 12; Faust, *Z.* 1871, 339).—5. By nitrating (2,4,1)-chloro-nitro-phenol (Armstrong; F. a. M.). 6. By nitrating (2,6,1)-chloro-nitro-phenol (F. a. M.).—7. From di-nitro-amido-phenol (picramic acid), by displacing NH_2 by Cl through the diazo-reaction (F.).—8. By the action of HNO_3 on di-chloro-phenol *p*-sulphonic acid (Armstrong, *C. J.* 24, 1112).—9. From di-chloro-*p*-nitro-phenol and HNO_3 (X.).—10. By nitrating *o*-chloro-phenol sulphonic acid (Armstrong a. Prevost, *B.* 7, 405).

Properties.—Yellowish laminæ (from alcohol) or irregular six-sided tables (from $CHCl_3$). Sl. sol. hot water, m. sol. alcohol and ether. Tastes bitter.

Salts.—$C_6H_2Cl(NO_2)_2(OK)$aq: short slender yellow needles.—NaA′ 1½aq: short yellow needles. —NH_4A' 1½aq.—NH_4A' (G.).—NH_4A'aq (F. a. S.). —BaA'_2 9aq (F. a. S.).—BaA'_2 10aq (F. a. M.).— CaA'_2 7aq: flat golden needles.—MgA'_2 7aq.— MgA'_2 10aq.—CuA'_2 8aq: greenish-yellow hair-like needles.—AgA′ aq.

Chloro-di-nitro-phenol $C_6H_2Cl(NO_2)_2(OH)$. [70°]. From di-chloro-di-nitro-benzene and aqueous NaOH (Engelhardt a. Latschinoff, *Z.* 1870, 234; Körner, *G.* 4, 395). Long needles.— BaA'_2 8aq: yellow needles.

Di-chloro-nitro-phenol $C_6H_2Cl_2(NO_2)(OH)$ [2:4:6:1]. [122°].

Formation.—1. By nitrating di-chloro-phenol [43°] (Fischer, *A. Suppl.* 7, 185; Chandelon, *B.* 16, 1752) or its sulphonic acid (Armstrong, *C. J.* 24, 1119; 25, 98).—2. By passing chlorine into an aqueous solution of *o*-nitro-phenol *p*-sulphonic acid (Schmitt a. Glutz, *B.* 2, 52).—3. By chlorinating chloro-nitro-phenol [87°] (Faust a. Saame, *A. Suppl.* 7, 195).—4. From *o*-chloro-phenol by successive nitration and chlorination (A.).— 5. By chlorinating chloro-nitro-phenol sulphonic acid (A.).—6. From di-chloro-*o*-oxy-benzoic acid by dissolving in HOAc and treating with HNO_3 (Smith a. Knerr, *Am.* 8, 95).

Properties.—Yellow laminæ (from alcohol). Sl. sol. water, forming a deep yellow solution. V. sol. alcohol and ether. Volatile with steam. Explodes when heated suddenly. HNO_3 forms chloro-di-nitro-phenol [81°]. Bromine and water at 100° form chloro-tri-bromo-quinone (Ling, *C. J.* 51, 781).

Salts. — $C_6H_2Cl_2(NO_2)(ONH_4)$: orange needles; may be sublimed.—NaA′: nodular groups of orange-red needles.—KA′: needles of the colour of CrO_3.—KA′aq (Faust, *A.* 173, 317). BaA'_2 2aq: orange needles, v. sl. sol. water.— MgA'_2 2aq.—PbA′(OH).—ZnA'_2 2aq.

Ethyl ether $C_6H_2Cl_2(NO_2)(OEt)$. [29°]. Pearly prisms.

Acetyl derivative $C_6H_2Cl_2(NO_2)(OAc)$. [77°]. From NaA′ and AcCl.

Di-chloro-nitro-phenol $C_6H_2Cl_2(NO_2)(OH)$ [6:2:4:1]. [125°].

Formation. — 1. By chlorinating *p*-nitro-phenol (Seifart, *A. Suppl.* 7, 198; Kollrepp, *A.* 234, 8).—2. By nitrating di-chloro-phenol sulphonic acid (Armstrong, *C. J.* 24, 1112; Faust, *Z.* 1871, 338).

Properties. — Slightly yellowish prisms or tables (from ether), or colourless needles (from chloroform). V. sl. sol. hot water; not volatile with steam. Converted by heat into di-chloro-quinone, NO, and N (Armstrong a. Brown, *B.* 7, 926). HNO_3 (S.G. 1·45) forms chloro-di-nitro-phenol [111°]. Bromine and water at 100° form di-chloro-di-bromo-quinone (Ling, *C. J.* 51, 786).

Salts.—$C_6H_2Cl_2(NO_2)(ONH_4)$ aq: shining yellow needles, becoming anhydrous and colourless over H_2SO_4.—NaA′ 5aq: yellow needles.— KA′aq: orange needles.—BaA'_2 3½aq: red needles (Ling, *C. J.* 51, 786).—BaA'_2 4aq (S.): brown-red laminæ or red needles.—BaA'_2 8aq: yellow needles (F. a. M.; *A.* 173, 311).—CaA'_2 9aq: golden needles or laminæ, v. sol. water.— CdA'_2 3½aq. — PbA'_2 4½aq. — CuA'_2 5aq. — MgA'_2 10aq: rosettes of yellow needles.—AgA′: colourless needles.

Ethyl ether $C_6H_2Cl_2(NO_2)(OEt)$ [85°].

Di-chloro-nitro-phenol $C_6H_2Cl_2(NO_2)(OH)$. Formed in small quantity by nitrating di-chloro-phenol with $ClSO_3H$ (Armstrong, *Z.* 1871, 679). Short yellow needles (from water).

Tri-chloro-nitro-phenol $C_6HCl_2(NO_2)(OH)$ [6:4:2:3:1]. [69°]. Obtained by saponifying its nitro-benzoyl derivatives, which are obtained by nitrating benzoyl-tri-chloro-phenol (Daccomo, *B.* 18, 1164). Glistening colourless needles. V. sol. alcohol, ether, and benzene, sl. sol. water. Fe_2Cl_6 gives a violet-blue colouration.

Salts.—$A'NH_4$: small yellow needles.— A′K aq.—A′Ag: small yellow needles.—A'_2Ba aq yellow plates.

o-Nitro-benzoyl derivative $C_6HCl_2(NO_2).OCO.C_6H_4(NO_2)$: [106° cor.]; colourless glistening scales; sol. alcohol and ether *m-Nitro-benzoyl derivative* $C_6HCl_3(NO_2).OCO.C_6H_4(NO_2)$: [146° cor.]; large colourless tables; sol. alcohol and ether, insol. water.

Ethyl ether (?) [54°]. From tri-chloro-phenetol and cold H_2SO_4 and HNO_3 (Faust, *A.* 149, 152).

Tri-chloro-nitro-phenol $C_6HCl_3(NO_2)(OH)$ [2:3:5:4:1]. [146°]. From tri-chloro-phenol [54°] and HNO_3. White needles. Reduces to tri-chloro-*p*-amido-phenol (Lampert, *J. pr.* [2] 33, 382).

Ethyl ether $C_6HCl_3(NO_2)(OEt)$. [69°].

Tri-chloro-di-nitro-phenol. *Ethyl ether* $C_6Cl_3(NO_2)_2(OEt)$. [100°]. From tri-chloro-phenetol and warm HNO_3 mixed with H_2SO_4 (Faust, *A.* 149, 152).

CHLORO-NITRO-PHENOL SULPHONIC ACID $C_6H_2Cl(NO_2)(OH)(SO_3H)$ [2:6:1:4]. From di-chloro-phenol sulphonic acid and cold HNO_3 (Armstrong, *C. J.* 24, 1117). Formed also by nitrating *o*-chloro-phenol sulphonic acid (Armstrong a. Prévost, *B.* 7, 404). An isomeric acid is formed by chlorinating nitro-phenol sulphonic acid (Armstrong a. Brown, *C. J.* 25, 872). HNO_3 converts it into chloro-di-nitro-phenol [111°]. Chlorine forms di-chloro-nitro-phenol [121°].

Salts.—$C_6H_2ClNSO_6K_2$: orange-red six-sided plates, v. e. sol. hot water.—$C_6H_3ClNSO_6K\frac{1}{2}aq$: yellow needles.

DI-CHLORO-DI-NITRO-DIPHENYL $C_6H_3(NO_2)Cl.C_6H_3(NO_2)Cl$. [140°]. Prepared by the nitration of di-chloro-diphenyl. [4:1] $C_6H_4Cl.C_6H_4Cl$ [1:4] (Schmidt a. Schultz, *B.* 12, 494). Small needles or long prisms. Sl. sol. cold, v. sol. hot, alcohol, and C_6H_6.

CHLORO-NITRO-DI-PHENYL-AMINE $C_{12}H_9ClN_2O_2$ *i.e.* $C_6H_5.NH.C_6H_3Cl(NO_2)$. [109°]. Slowly formed, together with benzene-azo-aniline (amido-azo-benzene) by mixing (1,3,4)-chloro-di-nitro-benzene [39°] (1 mol.) with aniline (3 mols.) (Laubenheimer, *B.* 9, 771). Long red needles (from alcohol). Does not combine with acids.

Nitrosamine $C_6H_5.N(NO).C_6H_3Cl(NO_2)$. [111°]. Yellow, six-sided laminæ, m. sol. cold alcohol.

CHLORO-DI-NITRO-DI-PHENYL-AMINE-*o*-CARBOXYLIC ACID $C_6H_2(NO_2)_2Cl.NH.C_6H_4.CO_2H$ [256°]. Formed by mixing alcoholic solutions of di-chloro-di-nitro-benzene $C_6H_2Cl_2(NO_2)_2$[1:4:2:6] and anthranilic acid $C_6H_4(NH_2)CO_2H$[1:2] and adding NH_3 (Jourdan, *B.* 18, 1454). Glistening red prisms. Sol. hot alcohol and acetic acid, insol. water.

Chloro-di-nitro-di-phenyl-amine-*o*-carboxylic acid $C_6H_3(NO_2)_2.NH.C_6H_3Cl.CO_2H$. [282° uncor.]. Obtained by mixing alcoholic solutions of chloro-di-nitro-benzene $C_6H_3Cl(NO_2)_2$[1:2:4] and chloro-amido-benzoic acid $C_6H_3Cl(NH_2)CO_2H$[1:4:5], and adding NH_3 (Jourdan, *B.* 18, 1450). Fine orange needles. V. sl. sol. cold alcohol and acetic acid, insol. water, benzene, and ligroïn. A'_2Ca: sl. sol. water.

TRI-CHLORO-DI-NITRO-DI-PHENYL-BUTANE $C_{16}H_{11}Cl_3(NO_2)_2$. From tri-chloro-di-phenyl-butane and fuming HNO_3 (Hepp, *B.* 7, 1420). Small yellowish tables (from alcohol). Sl. sol. CS_2, v. sol. ether.

CHLORO-NITRO-PHENYLENE-DIAMINE $C_6H_2Cl(NO_2)(NH_2)_2$[1:4:3:5]. [192°–194°]. From $C_6H_2Cl_3(NO_2)$[1:3:5:2] and alcoholic NH_3 at 200° for several days (Beilstein a. Kurbatoff, *A.* 192, 233). Red needles. V. sol. alcohol, sol. dilute (50 per cent.) acetic acid or benzene, sl. sol. light petroleum.

DI-CHLORO-NITRO-PHENYL-ETHANE *v.* DI-CHLORO-NITRO-ETHYL-BENZENE.

Penta-chloro-di-nitro-di-phenyl-ethane $C_{14}H_7Cl_5N_2O_4$ *i.e.* $CCl_3.CH(C_6H_3Cl.NO_2)_2$. [148°]. From $CCl_3.CH(C_6H_4Cl)_2$ and fuming HNO_3 (Zeidler, *B.* 7, 1181). Needles (from alcohol).

CHLORO-NITRO-PHENYL MERCAPTAN $C_6H_4ClNSO_2$ *i.e.* $C_6H_3Cl(NO_2)(SH)$ [3:6:1]. [171°]. From (3,6,1)-chloro-di-nitro-benzene and alcoholic KSH (Beilstein a. Kurbatoff, *A.* 197, 82). Yellow needles, v. sol. chloroform, v. sl. sol. alcohol.

Chloro-nitro-phenyl mercaptan $C_6H_3Cl(NO_2)(SH)$ [4:2:1]. [213°]. From (1,4,2)-di-chloro-nitro-benzene and alcoholic KSH (Beilstein a. Kurbatoff, *A.* 197, 79). Yellow tables (from HOAc). Sl. sol. alcohol. Alcoholic ammonium sulphide converts it into $C_{12}H_8Cl_2N_2S_2$ [147°], which crystallises in yellow needles, and is converted by HNO_3 into $C_6H_3ClN_2S$ [104°].

CHLORO-NITRO-PHENYL-*m*-PHENYLENE-DIAMINE $NH_2.C_6H_4.NH.C_6H_3Cl(NO_2)$. [151°]. Red needles. Sl. sol. cold alcohol. Prepared by warming an alcoholic solution of *m*-phenylene-diamine and (1,3,4)-chloro-di-nitro-benzene. Forms with acids unstable yellow salts (Laubenheimer, *B.* 11, 1158).

(*Py.* 4:1:2)-**CHLORO-NITRO-PHENYL-ISO-QUINOLINE** $C_{15}H_9ClO_2N_2$ *i.e.* C_6H_4
$$C_6H_4\left\langle\begin{array}{l}C(NO_2){:}CPh\\ \qquad\quad|\\ CCl{=\!=}N\end{array}\right.$$

[156°]. Formed by heating nitro-oxy-phenyl-isoquinoline (nitro-iso-benzal-phthalimidine) with $POCl_3$ (Gabriel, *B.* 19, 834). Small yellow needles or prisms. V. sol. hot acetic acid, benzene, chloroform, ether, and CS_2; sl. sol. alcohol, v. sl. sol. ligroïn. By HI and P it is reduced to amido-phenyl-isoquinoline. Heated with alcoholic sodium ethylate it yields the ethyl-ether of nitro-oxy-phenyl-isoquinoline.

DI-CHLORO-DI-NITRO-DI-PHENYL-SULPHIDE $(C_6H_3Cl.NO_2)_2S$. [150°]. Yellow needles. Almost insol. alcohol, sl. sol. acetic acid. Prepared by the action of alcoholic K_2S on (1, 4, 6)-di-chloro-nitro-benzene (Beilstein a. Kurbatow, *B.* 11, 2056; *A.* 197, 79).

CHLORO-NITRO-PHENYL-*p*-TOLYL-AMINE $C_6H_4Me.NH.C_6H_3Cl(NO_2)$. [124°]. Small red needles. Sl. sol. cold alcohol. Prepared by the action of a cold alcoholic solution of *p*-toluidine on (1, 3, 4)-chloro-di-nitro-benzene (Laubenheimer, *B.* 11, 1157).

DI-CHLORO-DI-NITRO-DI-PHENYL-UREA $C_{13}H_8Cl_2N_4O_5$ *i.e.* $CO(NH.C_6H_3Cl.NO_2)_2$. [210°]. From di-chloro-di-phenyl-guanidine and HNO_3 (Losanitsch, *Bl.* [2] 32, 170). Yellow tables, insol. water, sl. sol. alcohol.

CHLORO-NITRO-PHTHALIC ACID $C_8H_4ClNO_6$ *i.e.* $C_6H_2Cl(NO_2)(CO_2H)_2$. From (γ) di-chloro-naphthalene and HNO_3 (Atterberg, *B.* 10, 547).—K_2A'': crystals; explodes above 300°

Di-chloro-nitro-phthalic acid. From (ζ)-tri chloro-naphthalene and HNO_3 (S.G. 1·2) at 150 (Widmann, *B.* 12, 960).

Tri-chloro-nitro-phthalic acid $C_8H_2Cl_3NO_6$. From ('α')-tri-chloro-naphthalene and HNO_3 (Atterberg a. Widmann, *B.* 10, 1844).

DI-CHLORO-DI-NITRO-PROPANE $C_3H_4Cl_2(NO_2)_2$ (?). From di-chloro-propylene (from tri-chloro-butyric aldehyde) and fuming HNO_3 (Pinner, *A.* 179, 49). Oil; converted by tin and HCl into $C_3H_4Cl_2$ (1 9°), $C_3H_4Cl_2(NH_2)_2$, and tri-chloro-nitro-propane

Tri-chloro-nitro-propane $C_3H_4Cl_3(NO_2)$. (c. 193°). Formed as above.

DI-CHLORO-NITRO-PROPYLENE $C_3H_3Cl_2(NO_2)$. (c. 159°). Formed by the action of aqueous NaOH upon di-chloro-di-nitro-propane and upon tri-chloro-nitro-propane (Pinner, *A.* 179, 57).

CHLORO-NITRO-QUINOLINE $C_9H_5Cl(NO_2)N$ [120°–128°]. Formed, together with the isomeride [186°], by nitration of (*B.* 1 or 3)-chloro-quinoline (La Coste a. Bodewig, *B.* 17, 927). V. sol. hot alcohol, sl. sol. water.

Chloro-nitro-quinoline $C_9H_5Cl(NO_2)N$. [186°]. Formed, together with the preceding, by nitration of (*B.* 1 or 3)-chloro-quinoline (La Coste a. Bodewig, *B.* 17, 927). Long colourless needles. Sl. sol. alcohol.

CHLORO-NITRO-QUINONE *Anilide* $C_6HCl(NO_2)(NHPh)O_2$ [6 or 2:3:2 or 6:4:1]. [208°]. Small red trimetric tables. Formed by the action of aniline in alcoholic solution upon di-chloro-nitro-quinone $C_6HCl_2(NO_2)O_2$ [6:2:3:4:1] (Guareschi a. Daccomo, *B.* 18, 1172).

Di-chloro-nitro-quinone $C_6HCl_2(NO_2)O_2$ [6:2:3:4:1]. [220°]. Formed by the action of a mixture of HNO_3 and H_2SO_4 upon the propionyl derivative of tri-chloro-phenol (Guareschi a. Daccomo, *B.* 18, 1171). Small yellow needles. Sol. cold alcohol, sl. sol. ether and CS_2, v. sl. sol. hot water.

CHLORO-ISO-NITROSO-ACETIC ETHER $N(OH):CCl.CO_2Et$(?). *Chloro-oximido-acetic ether.* [80°]. From chloro-aceto-acetic ether (*v.* Allihn, *B.* 11, 567) and fuming HNO_3 (Pröpper, *A.* 222, 50). Glittering columns (from ether). V. e. sol. alcohol and ether. Boiling water splits it up into hydroxylamine, oxalic acid, and alcohol.

CHLORO-ISO-NITROSO-ACETONE $CH_2.CO.CCl(NOH)$. *Mono-oxim of ω-chloro-pyruvic aldehyde.* [110°]. Formed in small quantity by treating chloro-acetone with fuming HNO_3 (Glutz, *Z.* 1870, 529; Barbaglia, *B.* 6, 321). Formed also by heating the product of the action of nitrous acid gas upon acetone ($(CH_3)_2C(ONO_2).C(NOH).CO.CH_3$(?)), with dilute HCl; acetone and HNO_2 are formed at the same time (Sandmeyer, *B.* 20, 640). Prisms or tables; v. sol. water, alcohol, and ether.

Oxim $CH_2.C(NOH).CCl(NOH)$. *Di-oxim of ω-chloro-pyruvic aldehyde. Chloro-methyl-glyoxim.* [171°]. Small white needles.

α-CHLORO-o-NITRO-STYRENE $C_8H_6ClNO_2$ *i.e.* $C_6H_4(NO_2).CCl:CH_2$. *Nitro-phenyl-chloro-ethylene.* From *o*-nitro-acetophenone and PCl_5 (Gevekoht, *A.* 221, 329). Oil.

α-Chloro-*p*-nitro-styrene $C_6H_4(NO_2).CCl:CH_2$ [64°]. From *p*-nitro-acetophenone and PCl_5 (Drewsen, *A.* 212, 162). Concentric groups of slender needles (from benzoline).

α-Chloro-ω-nitro-styrene $Ph.CCl:CH.NO_2$ [49°]. From $PhCHCl.CHCl.NO_2$ and aqueous NaOH (Priebs, *A.* 225, 345). Golden plates (from light petroleum). Insol. water, soluble, when finely divided, in alkalis.

ω-Chloro-*o*-nitro-styrene $C_6H_4(NO_2).CH:CHCl$. [59°]. Formed as a by-product in the preparation of chloro-*o*-nitro-oxy-phenyl-propionic acid by the action of hypochlorous acid on *o*-nitro-cinnamic acid (Lipp, *B.* 17, 1070). Glistening needles or prisms. V. sol. ether and hot alcohol, sl. sol. hot water, insol. cold water.

TRI-CHLORO-NITRO-THIOPHENE $C_4SCl_3(NO_2)$. [86°] Formed by nitration of tri-chloro-thiophene. Reddish-yellow felted needles. V. sol. benzene and ether, less in alcohol (Rosenberg, *B.* 12, 652).

CHLORO-NITRO-TOLUENE $C_6H_3(CH_3)Cl(NO_2)$ [1:4:3]: [9°]. (260° i. V.). S.G. $\frac{12}{22}$ 1·297.

Formation.—1. Together with the (1:2:4)-isomeride by nitration of *p*-chloro-toluene (10 pts.) with a cold mixture of conc. HNO_3 (12 pts.) and conc. H_2SO_4 (17 pts.) (Engelbrecht, *B.* 7, 797; Goldschmidt a. Hönig).—2. From *m*-nitro-*p*-toluidine $C_6H_3(CH_3)(NO_2)(NH_2)$ [1:3:4] by the action of Cu_2Cl_2 upon the diazo- compound (Gattermann a. Kaiser, *B.* 18, 2599).

Reaction.—On reduction it gives *p*-chloro-*m*-toluidine [28°] (Goldschmidt a. Hönig, *B.* 19, 2438).

(α)-Chloro-nitro-toluene $C_6H_3(CH_3)Cl(NO_2)$ [1:2:*x*]. (250°). Oil. Formed by nitration of *o*-chloro-toluene. On reduction it gives a chloro-toluidine [83°] (Goldschmidt a. Hönig, *B.* 19, 2443; *cf.* Wroblewsky, *A.* 168, 200).

Chloro-nitro-toluene $C_6H_3(CH_3)Cl(NO_2)$ [1:4:2]. [38°]. (240° at 718 mm.).

Formation.—1. Together with the [1:3:4] isomeride, by nitration of *p*-chloro-toluene (10 pts.) with a cold mixture of conc. HNO_3 (12 pts.) and conc. H_2SO_4 (17 pts.) (Engelbrecht, *B.* 7, 797; Goldschmidt a. Hönig, *B.* 19, 2438).—2. From *o*-nitro-*p*-toluidine by the action of Cu_2Cl_2 upon the diazo- compound (Beilstein a. Kuhlberg, *A.* 158, 336).

Properties.—Needles; sl. sol. cold alcohol, volatile with steam. On reduction it gives *p*-chloro-*o*-toluidine [22°] (Goldschmidt a. Hönig, *B.* 19, 2438).

Chloro-nitro-toluene $C_6H_3MeCl(NO_2)$ [1:2:5] [44°]. (248°) at 711 mm. Obtained by the action of Cu_2Cl_2 upon diazotised nitro-*o*-toluidine $C_6H_3Me(NH_2)(NO_2)$ [1:2:5]. Needles (from ether) (Goldschmidt a. Hönig, *B.* 20, 199).

Chloro-nitro-toluene $C_6H_3(CH_3)Cl(NO_2)$ [1:3:5]. [55°]. Formed from *m*-nitro-*m*-toluidine $C_6H_3Me(NO_2)NH_2$ [1:3:5] by the action of cuprous chloride upon the diazo- compound. Yellow needles (from alcohol). Volatile with steam (Hönig, *B.* 20, 2419).

Chloro-nitro-toluene $C_6H_3(CH_3)(Cl)(NO_2)$ [1:2:4]. [65½°]. Formed by the action of PCl_5 on *p*-nitro-toluene (Lellmann, *B.* 17, 534; *cf.* Wachendorff, *A.* 185, 273). Colourless crystals. V. sol. alcohol. Volatile with steam. On reduction it gives chloro-*p*-toluidine [26°] (238°).

Chloro-di-nitro-toluene $C_6H_2(CH_3)Cl(NO_2)_2$ [1:4:3:5]. [48°]. Formed by nitration of chloro-nitro-toluene $C_6H_3(CH_3)Cl(NO_2)$ [1:4:3]. Long white needles (Hönig, *B.* 20, 2420).

Chloro-di-nitro-toluene $C_6H_2(CH_3)(NO_2)_2Cl$ [1:2?:6?:4]. [76°]. Small yellow needles (from ether). Formed by nitration of *p*-chloro-toluene with fuming HNO_3 (Goldschmidt a. Hönig, *B.* 19, 2439).

Chloro-di-nitro-toluene $C_6H_2(CH_3)Cl(NO_2)_2$ [1:4:2:6]. [101°]. Formed by nitration of *p*-chloro-*o*-nitro-toluene $C_6H_3(CH_3)(NO_2)Cl$ [1:2:4]. Long white needles (Hönig, *B.* 20, 2420).

Di-chloro-nitro-toluene $C_6H_2(CH_3)Cl_2(NO_2)$. [-14°]. (274°). S.G. ^{11} 1·455. From di-chloro-toluene and fuming HNO_3 (Wroblewsky, *A.* 168, 212). Oil.

(β)-Di-chloro-nitro-toluene $C_6H_2(CH_3)Cl_2(NO_2)$ [1:2:4:?]. [53°]. Formed by the action of conc. HNO_3 on (α)-dichlorotoluene (Seelig, *A.* 237, 163). Long needles (from methyl alcohol).

(α)-Di-chloro-di-nitro-toluene $C_6H(CH_3)Cl_2(NO_2)_2$ [1:2:3:?:?]. [122°]. Formed by the action of HNO_3 (2 pts.) and H_2SO_4 (1 pt.) on (α)-di-chloro-toluene (10 pts.) (Seelig, *A.* 237, 163). Needles (from methyl alcohol). Yields on reduction a diamine which is apparently meta.

(β)-Di-chloro-di-nitro-toluene $C_6H(CH_3)Cl_2(NO_2)_2$ [1:2:4:5:6]. [102°]. Formed by the action of a mixture of HNO_3 (2 pts.) and H_2SO_4 (1 pt.) on (β)-chloro-toluene (10 pts.) (Seelig, *A.* 237, 163). Needles.

(α)-Tri-chloro-nitro-toluene $C_6H(CH_3)Cl_3(NO_2)$. [92°]. S. (alcohol) 4·5 at 20° (Schultz, *A.* 187, 277). Formed by dissolving (α)-trichlorotoluene in conc. HNO_3 (Seelig, *A.* 237, 139; *B.* 18, 422; Beilstein a. Kuhlberg, *A.* 152, 240). Colourless plates (from alcohol).

(β)-Tri-chloro-nitro-toluene $C_6H(CH_3)Cl_3(NO_2)$. [60°]. Formed by dissolving (β)-trichlorotoluene in conc. HNO_3 (Seelig, *A.* 237, 140). Long yellow needles.

(α-) Tri-chloro-di-nitro-toluene $C_6(CH_3)Cl_3(NO_2)_2$. [227°]. Formed by warming (α)-trichlorotoluene with a mixture of conc. HNO_3 and H_2SO_4 (Schultz, *A.* 187, 280; Seelig, *A.* 237, 140; *B.* 18, 422). White plates or needles; v. sl. sol. alcohol. Reduced by tin and HCl to tri-chloro-tolylene-*p*-diamine.

(β-) Tri-chloro-di-nitro-toluene $C_6(CH_3)Cl_3(NO_2)_2$. [141°]. Formed by warming (β)-trichlorotoluene with a mixture of conc. HNO_3 and H_2SO_4 (Seelig, *A.* 237, 140; *B.* 18, 422). Light yellow needles, sl. sol. alcohol. Alcoholic NH_3 at 100° gives tri-chloro-nitro-toluidine [191°].

CHLORO-NITRO-TOLUENE SULPHONIC ACID $C_7H_6ClNSO_5$ *i.e.* $C_6H_2(CH_3)Cl(NO_2)(SO_3H)$. From liquid (α)-chloro-nitro-toluene and fuming sulphuric acid (Wroblewsky, *A.* 168, 204).—BaA'_2 4aq: needles, sl. sol. water.

(α)-TRI-CHLORO-NITRO-TOLUIDINE $C_6(CH_3)(NO_2)Cl_3(NH_2)$. [191°]. Formed by the action of alcoholic NH_3 upon tri-chloro-di-nitro-toluene [227°] (Seelig, *B.* 18, 423; *A.* 237, 140). Orange-yellow needles (from alcohol).

(β)-Tri-chloro-nitro-toluidine $C_6(CH_3)(NO_2)Cl_3(NH_2)$. [192°]. Formed by the action of alcoholic NH_3 upon tri-chloro-di-nitro-toluene [141°] (Seelig, *B.* 18, 423). Orange-red needles (from alcohol).

TRI-CHLORO-DI-NITRO-DI-TOLYL-ETHANE $C_{16}H_{13}Cl_3(NO_2)_2$. [122°]. From tri-chloro-di-tolyl-ethane $(C_7H_7)_2CH.CCl_3$ and fuming HNO_3 (O. Fischer, *B.* 7, 1191). Short yellowish prisms.

DI-ω-CHLORO-NITRO-XYLENE $C_6H_3(NO_2)(CH_2Cl)_2$. [45°]. From di-ω-chloro-*p*-xylene and fuming HNO_3 (Grimaux, *Z.* 1871, 598). Small plates. V. sol. ether.

Di-chloro-di-nitro-xylene $C_6(CH_3)_2Cl_2(NO_2)_2$. [225°]. Formed by nitrating di-chloro-*p*-xylene (Kluge, *B.* 18, 2098). Needles.

CHLORO-OCTANE *v.* Octyl chloride.

Di-chloro-octane $C_8H_{16}Cl_2$ *i.e.* $C_6H_{13}.CCl_2.CH_3$. (c. 195°). From methyl hexyl ketone and PCl_5 (Dachauer, *A.* 106, 271).

Di-chloro-octane $C_8H_{16}Cl_2$. (c. 199°). From Cl and the octylene from castor oil (D.; *cf.* Béhal, *Bl.* [2] 47, 33).

Di-chloro-octane $C_8H_{16}Cl_2$. (c. 235°). Formed by the action of Cl on a mixture of octylene and octane derived from paraffin (Thorpe a. Young, *A.* 165, 16).

CHLORO-OCTYL ALCOHOL $C_8H_{17}ClO$. S.G. ^{0} 1·003; ^{21} ·987. From octylene and very dilute ($\frac{3}{4}$ p.c.) aqueous HOCl (De Clermont, *Z.* 1870, 411). Oil.

CHLORO-OCTYL-BENZENE $C_6H_4(C_8H_{17})Cl$. (270°–275°). Formed by chlorination of octyl-benzene in presence of a trace of iodine. Oil. V. sol. alcohol and ether, insol. water (Ahrens, *B.* 19, 2719).

CHLORO-OPIANIC ACID *v.* Opianic acid.

TRI-CHLORO-ORCIN (?) $C_7H_5Cl_3O_2$ *i.e.* $C_6(CH_3)Cl_3(OH)_2$. [59°]. From orcin and Cl (Schunck, *A.* 54, 271) or HCl and $KClO_3$ (De Luynes, *A.* 130, 34). Slender needles.

Tri-chloro-orcin $C_6(CH_3)Cl_3(OH)_2$. [123°]. From the pentachloride, HI, and phosphorus (Stenhouse, *Tr.* 1848, 88; *Pr.* 20, 72). Needles (from water) or plates (from HOAc), m. sol. CS_2, m. sol. benzene, v. e. sol. alcohol and ether. Volatile with steam. HIAq and phosphorus at 180° convert it into orcin. K_3FeCy_6 oxidises it to di-chloro-oxy-toluquinone [157°].

Penta-chloro-orcin $C_6(CH_3)Cl_3(OCl)_2$ or $C_6(CH_3)Cl(Cl_2)_2O_2$. [120·5°]. According to Stenhouse, this, and not tri-chloro-orcin, is formed by treating orcin with $KClO_3$ and HCl. Prisms (from CS_2). M. sol. CS_2 and benzene, v. sol. ether. Boiling water or alcohol decompose it with formation of tri-chloro-orcin. Liberates iodine from KI, and gives a pp. of AgCl with $AgNO_3$ (Liebermann a. Dittler, *A.* 160, 265).

Compound $C_6(CH_3)Cl_3(OCl)_2HClO$. [140·5°]. From orcin, calcium hypochlorite, and HCl. Prisms (from benzene). V. sol. ether, sl. sol. CS_2. Converted by NH_3 into $C_6H_5Cl_3NO$ [187°] (Stenhouse, *B.* 6, 575).

CHLORO-OXALAMYLINE *v.* Chloro-iso-butyl-isoamyl-glyoxaline.

CHLORO-OXALETHYLINE *v.* Chloro-methyl-ethyl-glyoxaline.

CHLORO-OXALMETHYLINE *v.* Chloro-methyl-glyoxaline.

CHLORO-OXALPROPYLINE *v.* Chloro-ethyl-propyl-glyoxaline.

CHLORO-OXETHOSE C_4Cl_6O. (210°). S.G. ^{11} 1·652. Formed from alcoholic K_2S and perchlorinated ether:

$$C_4Cl_{10}O + 2K_2S = 4KCl + S_2 + C_4Cl_6O$$

(Malaguti, *A. Ch.* [3] 16, 19). Oil; smells like meadow-sweet. Has a sweet taste.

Reactions.—1. In sunlight it re-combines with *chlorine* $C_4Cl_6O + 2Cl_2 = C_4Cl_{10}O$.—2. *Chlorine water* forms trichloracetic acid.

CHLORO - OXIMIDO - ACETIC ETHER *v.* Chloro-isonitroso-acetic ether.

CHLORO-OXINDOLE *v.* Oxindole.

Chloro-oxindole chloride *v.* Di-chloro-indole.

CHLORO-DI-OXY-ACETIC ACID *Chloro-glyoxylic acid.*

Diethyl derivative of the Nitrile $ClC(OEt)_2CN$. (c. 160°). Obtained, impure, from $CCl_2(OEt)CN$ and NaOEt (Bauer, *A.* 229, 176). Polymerises.

Dipropyl derivative of the Nitrile $ClC(OPr)_2CN$. (c. 201°). From $CCl_2(OPr)CN$ and NaOPr. Polymerises.

TETRA - CHLORO - TETRA - OXY - ADIPIC ETHER. *Anhydride* $C_{10}H_{10}Cl_4O_6$ *i.e.* $EtO_2C.CCl_2.CO.CO.CCl_2.CO_2Et$. *Oxalyl-di-chloro-acetic ether.* [93°]. Formed by the action of chlorine upon di-oxy-quinone-di-carboxylic ether. Slightly greenish prisms. By hot alcoholic NH_3 it is split up into 1 mol. of oxamide and 2 mols. of di-chloro-acetamide (Hantzsch a. Lœwy, *B.* 19, 26, 2385; Hantzsch a. Zeckendorf, *B.* 20, 1808).

DI-CHLORO-DI-OXY-DI-AMIDO-BENZENE *v.* Di-chloro-di-amido-hydroquinone.

DI - CHLORO - DI - OXY - AMIDO - PYRIDINE $C_5H_4Cl_2O_2N_2$ probably  $N\Big\langle\begin{matrix}C(OH)=CCl\\ C(OH)-CCl\end{matrix}\Big\rangle C.NH_2$. *Di-chloro-glutazine.* [242°]. Formed in small quantity, together with tri-chloro-oxy-amido-pyridine, tri-chloro-amido-pyridine, and tetra-chloro-amido-pyridine, by heating glutazine with PCl_5 (6 or 7 pts.). Short flat colourless needles. Sl. sol. hot water and alcohol. Dissolves readily in aqueous acids and alkalis. Combines with bromine (Stokes a. Pechmann, *B.* 19, 2710; *Am.* 8, 391).

Di-ethyl derivative  $N\Big\langle\begin{matrix}C(OEt):CCl\\ C(OEt).CCl\end{matrix}\Big\rangle C.NH_2$: [98°]. Long colourless needles. Readily sublime. Volatile with steam. V. sol. alcohol and ether, insol. water. Formed together with the mono-ethyl derivative by heating tetra-chloro-amido-pyridine with an excess of sodium ethylate at 190° for 3 or 4 hours.

Mono-ethyl derivative  $N\Big\langle\begin{matrix}C(OH):CCl\\ C(OEt).CCl\end{matrix}\Big\rangle C.NH_2$: [162°]. Flat needles. Sublimable. Not volatile with steam. V. sol. alcohol and ether, sl. sol. hot water. Dissolves in alkalis, but not in dilute acids. It is also formed by heating tri-chloro-oxy-amido-pyridine with sodium ethylate.—A'Na: glistening rhombic tables (Stokes a. Pechmann, *B.* 19, 2710; *Am.* 8, 396).

TRI - CHLORO - OXY - AMIDO - PYRIDINE $C_5H_3Cl_3N_2O$ probably  $N\Big\langle\begin{matrix}C(OH):CCl\\ CCl-CCl\end{matrix}\Big\rangle C.NH_2$. [282°]. Formed, together with an equal quantity of tetra-chloro-amido-pyridine and small quantities of di-chloro-di-oxy-amido-pyridine and tri-chloro-amido-pyridine, by heating glutazine with PCl_5 (6 to 7 pts.). Flat colourless needles. Sublimable. V. sol. hot water, nearly insol. cold, m. sol. hot alcohol, sl. sol. cold, sl. sol. ether and benzene, insol. ligroïn. Monobasic acid, decomposes soluble carbonates. Dissolves in conc. HCl or conc. H_2SO_4, but is reprecipitated on dilution.—A'Na aq: needles, m. sol. cold water.

Ethyl derivative  $N\Big\langle\begin{matrix}C(OEt):CCl\\ CCl-CCl\end{matrix}\Big\rangle C.NH_2$: [82°]. Colourless needles. Very volatile with steam. Peculiar odour. V. sol. alcohol, ether, etc. Formed by ethylation of the above, or by heating tetra-chloro-amido-pyridine with sodium ethylate (Stokes a. Pechmann, *B.* 19, 2710; *Am.* 8, 392).

γ-CHLORO-α-OXY-ANGELIC ACID $C_5H_7ClO_3$ *i.e.* $CH_3.CCl:CH.CH(OH).CO_2H$. [116°]. From tri-chloro-oxy-valeric acid, zinc, and HCl (Pinner a. Bischoff, *A.* 179, 100; Pinner a. Klein, *B.* 11, 1496). V. sol. water, alcohol, and ether, sl. sol. CS_2. Combines with Br. PCl_5 gives $CH_3.CCl:CH.CHCl.COCl$. — ZnA'_2. — CuA'_2. — AgA': needles, m. sol. cold water.

Ethyl ether EtA'. (230°).

Isobutyl ether $CH_2Pr.A'$. (c. 238°).

CHLORO-DI-OXY-ANTHRAQUINONE $C_{14}H_7ClO_4$. *Chloro-alizarin.* [24[illegible]°–248°]. Prepared by the action of Cl on a cold solution of alizarin in CS_2 (Diehl, *B.* 11, 187). Sublimes in red needles. Sol. boiling, sl. sol. cold, water.

Di-chloro-di-oxy-anthraquinone $C_{14}H_6Cl_2O_4$. *Di-chloro-alizarin.* [208°–210°]. Prepared by the action of $SbCl_5$ on alizarin (Diehl, *B.* 11, 188). Sublimes in beautiful orange-red spikes. Combines with mordants readily, the colours resembling those produced by nitro-alizarin.

Tetra-chloro-di-oxy-anthraquinone $C_{14}H_2(OH)_2Cl_4O_2$. *Tetra-chloro-alizarin.* [c. 260°]. Prepared by the action of $SbCl_5$ on alizarin (Diehl, *B.* 11, 189). Further action of $SbCl_5$ forms C_6Cl_6, C_2Cl_6, CCl_4, and CO_2. Reddish-brown crystalline powder. Does not combine with mordants.

CHLORO-OXY-BENZAMIDE *v.* Amide of Chloro-oxy-benzoic acid.

DI-CHLORO-TETRA-OXY-BENZENE $C_6Cl_2(OH)_4$. *Hydrochloranilic acid.* From di-chloro-di-oxy-quinone by reduction with aqueous SO_2 at 100°, or with tin and HCl (Koch, *Z.* 1868, 203; Graebe, *A.* 146, 32). Needles. V. sol. water, alcohol, and ether. Oxidised by moist air into di-chloro-di-oxy-quinone (chloranilic acid).

Tetra-acetyl derivative $C_6Cl_2(OAc)_4$. [235°].

CHLORO-*o*-OXY-BENZOIC ACID $C_7H_5ClO_3$ *i.e.* $C_6H_3Cl(OH).CO_2H$ [5:2:1]. *Chloro-salicylic acid.* Mol. w. 175½. [172·5°] (H. a. B.); [168°] (V.). S. ·09 at 20°; 1·25 at 100°.

Formation.—1. By passing the calculated quantity of chlorine into salicylic acid dissolved in a large quantity of CS_2 (Hübner a. Brenken, *B.* 6, 174; *cf.* Cahours, *A. Ch.* [3] 13, 106), or in HOAc (Smith, *B.* 11, 1226; Marshall, *A. Ph. S.* 17, 476).—2. From (5,2,1)-chloro-amido-benzoic acid by displacement of NH_2 by OH through the diazo- reaction (Hübner a. Weiss, *B.* 6, 175).—3. From (2,5,1)-oxy-amido-benzoic acid by displacement of NH_2 by Cl (Schmitt, *Z.* 1864, 321; Beilstein, *B.* 8, 816).—4. From *p*-chloro-phenol, CCl_4, and alcoholic KOH (Hasse, *B.* 16, 2196).—5. From $C_6H_4Cl(ONa)$ [1:4] and CO_2 at 150° (Varnholt, *J. pr.* [2] 36, 20).

Properties.—Needles (from water). V. sol. alcohol, ether, and benzene. Fe_2Cl_6 colours its aqueous solution red.

Salts.—NaA'.—LiA 2aq.—KA'.—BaA'$_2$ 8aq. CaA'$_2$ 8aq.—PbA'$_2$.—CuA'$_2$.—AgA'.

Methyl ether MeA'. [48°]. (249°). Needles.

Ethyl ether EtA'. [110°]. Needles.

Acetyl derivative $C_6H_3Cl(OAc).CO_2H$ [149°].

Amide $C_6H_3Cl(OH)(CONH_2)$ [223°].

Chloro-oxy-benzoic acid $C_6H_3Cl(OH).CO_2H$ [3:2:1]. [178°]. S. ·08 at 8·5°. From [2:1] $C_6H_4Cl(ONa)$ and CO_2 at 150° (Varnholt, *J. pr.* [2] 36, 22). Long needles, volatile with steam, may be sublimed. V. sol. alcohol and chloroform. Fe_2Cl_6 gives a violet colour.—NaA'.—BaA'$_2$ 8aq.

Methyl ether MeA'. [83°]. (260°). Needles.

Chloro-oxy-benzoic acid $C_6H_3Cl(OH).CO_2H$ [4:2:1]. [207°]. From $C_6H_4Cl(ONa)$ [1:3] by treatment with CO_2 and heating the product, $C_6H_4Cl(O.CO_2Na)$ at 150° (Varnholt, *J. pr.* [2] 36, 28). Also from $C_6H_3(CO_2H)(NO_2)Cl$ [1:2:4] by reduction, diazotisation, and boiling with water. Small needles, volatile with steam, may be sublimed. V. sol. alcohol and chloroform, sl. sol. water. Fe_2Cl_6 gives a violet colour.

Chloro-*p*-oxy-benzoic acid $C_6H_3Cl(OH)CO_2H$ [3:4:1]. [188°] (P.); [170°] (L.). S. ·37 at c. 15°.

Formation.—1. From silver *p*-oxy-benzoate and Cl (Peltzer, *A.* 146, 284; *Z.* [2] 5, 225).—2. From *p*-oxy-benzoic acid and $SbCl_5$ (Lössner, *J. pr.* [2] 13, 432).—3. From *o*-chlorophenol, KOH, CCl_4 and alcohol at 130° (Hasse, *B.* 10, 2192).

Properties.—Silky needles; v. sol. hot water, v. e. sol. alcohol and ether. May be sublimed. Fe_2Cl_6 gives a reddish-brown pp. in neutral solutions.

Salt.—BaA'$_2$ 6aq.

Methyl derivative $C_6H_3Cl(OMe).CO_2H$. *Chloro-anisic acid.* [215°]. White glistening scales. Formed by oxidation of the methyl-ether of chloro-*p*-cresol.—A'Ag: sparingly soluble pointed plates.—A'$_2$Ba 3½aq: thin rectangular tables, soluble in hot water (Schall a. Dralle, *B.* 17, 2529).

Chloro-*p*-oxy-benzoic acid. *Methyl derivative* $C_6H_3Cl(OMe)CO_2H$. *Chloro-anisic acid.* [176°] (C.); [180°] (L.). From anisic acid and Cl (Laurent, *B. J.* 23, 421; Cahours, *A.* 56, 312). Prisms or needles. May be sublimed. Insol. water, v. sol. alcohol and ether. Probably identical with the preceding.

Di-chloro-*o*-oxy-benzoic acid $C_6H_2Cl_2(OH)(CO_2H)$. *Di-chloro-salicylic acid.* [214°]. Prepared by leading Cl into an acetic acid solution of salicylic acid (Smith, *B.* 11, 1225; *A. Ph. S.* 17, 486; *cf.* Cahours, *A. Ch.* [3] 13, 106). Formed also by heating salicylic acid (1 mol.) with $SbCl_5$ (3½ mols.) (Lössner, *J. pr.* [2] 13, 429). Small prisms (from dilute alcohol). Sl. sol. hot water. May be sublimed.

Salts.—A'$_2$Ba 3aq. Long needles, insol. cold water.—A'K: soluble needles.—A'Na: large soluble needles.—A'$_2$Mg: small soluble crystals. A'$_2$Pb. Insoluble pp.

Methyl ether: [142°]; needles.

Ethyl ether: [47°]; needles.

Iso-butyl ether: [188°]; small needles.

Amide: [209°]; needles.

Methyl derivative $C_6H_2Cl_2(OMe)CO_2H$ [104°]. From methyl-salicylic acid and Cl (Procter, *J. Ph.* [3] 3, 275; Cahours, *A. Ch.* [3] 10, 348). Needles.

Ethyl derivative $C_6H_2Cl_2(OEt)CO_2H$. Needles (Cahours, *A. Ch.* [3] 27, 461).

Di-chloro-*p*-oxy-benzoic acid $C_6H_2Cl_2(OH).CO_2H$ [156° uncor.]. Formed by oxidation of di-chloro-*p*-cresol with CrO_3 in acetic acid (Claus a. Riemann, *B.* 16, 1600). Sublimable. Long white needles. Sol. alcohol, ether, and hot water, nearly insol. cold water.—A'Na×: small needles, sol. water and alcohol.

Di-chloro-*p*-oxy-benzoic acid. *Methyl derivative* $C_6H_2Cl_2(OMe).CO_2H$. *Di-chloro-anisic acid* [196°]. Formed, together with tetra-chloro-quinone, by treating anisic acid with HCl and $KClO_3$ (Reinecke, *Bl.* [2] 7, 177). Large needles (from alcohol); insol. water.

CHLORO-*o*-OXY-BENZOIC ALDEHYDE $C_7H_5ClO_2$ *i.e.* $C_6H_3Cl(OH).CHO$. From salicylic aldehyde and Cl (Piria, *A.* 30, 169; Löwig, *B. J.* 20, 311). Tables (from alcohol). Insol. water. Combines with $NaHSO_3$ (Bertagnini, *A.* 85, 196). $Ba(O.C_6H_3Cl.CHO)_2$: powder. With NH_3 it forms yellow needles of $(C_6H_3Cl(OH).CH)_3N_2$ (Piria, *A. Ch.* [2] 69, 309).

Chloro-*p*-oxy-benzoic aldehyde $C_6H_3Cl(OH).CHO$. [149°]. From *p*-oxy-benzoic aldehyde and dry chlorine (Herzfeld, *B.* 10, 2196). Silky needles; v. sol. water, alcohol, and ether. Absorbs NH_3 (2 mols.). Fe_2Cl_6 gives a violet colour.

CHLORO-OXY-BENZYL ALCOHOL $C_7H_7ClO_2$ *i.e.* $C_6H_3Cl(OH).CH_2OH$, *Chloro-saligenin.* From chloro-salicin by hydrolysis by emulsin (Piria, *A.* 56, 60). Trimetric plates (from water). Turned blue by Fe_2Cl_6.

α-CHLORO-β-OXY-BUTYRIC ACID $CH_3.CH(OH).CHCl.CO_2H$. [63°]. Prepared by addition of hypochlorous acid (ClOH) to (α)-crotonic acid (Melikoff, *B.* 16, 1270; *Bl.* [2] 41, 311; 47, 167; Pavoloff, *Bl.* [2] 43, 115). Needles. V. sol. water.

Reactions.—1. By the action of alcoholic KOH it gives propylene-oxide-carboxylic ((β)-methyl-glycidic) acid

$CH_3.CH.CH.CO_2H$ [84°]

whence HCl forms the following acid.—2. Heating with H_2SO_4 gives α-chloro-crotonic acid whence zinc and H_2SO_4 produce crotonic acid.—3. Heating with HCl gives $CH_3.CHCl.CHCl.CO_2H$ [69°] (?) whence alcoholic KOH gives rise to $CH_3.CH:CCl.CO_2H$ [98°].

Salts.—A'$_2$Zn: extremely soluble tables.—A'$_2$Ca: easily soluble amorphous powder.

Chloro-oxy-butyric acid $C_3H_5Cl(OH).CO_2H$. [82°].

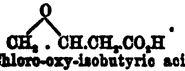
Formation.—1. By the addition of hypochlorous acid (ClOH) to iso-crotonic acid.—2. By the addition of HCl to propylene oxide carboxylic acid.

Properties.—Long prisms. V. sol. water, alcohol and ether. By the action of alcoholic KOH it gives butyro-glycidic acid.

Salts.—A'$_2$Ca 4aq: easily soluble microscopic crystals.—A'$_2$Zn 2aq: trimetric crystals, sl. sol. cold water (Melikoff, *B.* 16, 1268).

Chloro-oxy-butyric acid $CH_2Cl.CH(OH).CH_2.CO_2H$. Formed at the same time as the preceding by the union of HOCl with isocrotonic acid (Melikoff, *J. R.* 16, 541).

Liquid. Converted by alcoholic KOH into propylene oxide carboxylic ((γ)-methyl-glycidic) acid



$CH_2.CH.CH_2.CO_2H$ (O bridging CH_2 and CH).

Chloro-oxy-isobutyric acid $CH_2Cl.CMe(OH).CO_2H$. *Chloro-acetonic acid.* [107°]. (c. 233°).

Formation.—1. From chloro-acetone by treatment with HCN and saponification of the resulting nitrile (Bischoff, *B.* 5, 865).—2. From methacrylic acid and HOCl (Melikoff, *Bl.* [2] 41, 311; 43, 116).—3. From propylene oxide carboxylic acid ((α)-methyl-glycidic acid)

$CH_2.C(CO_2H).CH_3$ and conc. HCl (M.).

Properties.—Long prisms (from ether); v. sol. water. Converted by alcoholic KOH into propylene-oxide carboxylic acid.

Salts.—CaA'_2 2aq.—ZnA'_2.

Nitrile $CH_2Cl.CMe(OH).CN$. From chloro-acetone, by boiling with alcohol and conc. aqueous HCN (B.). Oil. Split up by distillation into HCy and $C_3H_4Cl_2O$.

Chloro-oxy-butyric acid. ***Nitrile*** $C_4H_6ClNO_2$. From epichlorhydrin and anhydrous HCy at 140° (Hörmann, *B.* 12, 23). Liquid, v. sol. water. Dilute HCl forms a liquid chloro-oxy-butyric acid.

Di-chloro-oxy-isobutyric acid $CHCl_2.CMe(OH).CO_2H$. [83°]. From its nitrile and HClAq at 100° (Bischoff, *B.* 8, 1334). Prisms.—AgA'.

Ethyl ether EtA'. (c. 212°).

Nitrile $CHCl_2.CMe(OH).CN$. From di-chloro-acetone and conc. aqueous HCy (B.). Liquid. Split up by distillation or by alkalis into HCy and di-chloro-acetone. Aqueous KCy forms crystalline $(C_3H_4Cl_2O)_2HCN$ (Glutz a. Fischer, *J. pr.* [2] 4, 52).

Di-chloro-oxy-isobutyric acid $(CH_2Cl)_2C(OH).CO_2H$. [92°]. Obtained by boiling its nitrile for 12 hours with conc. HClAq (Grimaux a. Adam, *Bl.* [2] 36, 20). Deliquescent tables, v. sol. alcohol and ether. KCN converts it into a nitrile of citric acid $(CH_2CN)_2C(OH).CO_2H$.

Ethyl ether EtA'. (c. 228°). From *s*-di-chlorhydrin, chloroformic ether, and sodium amalgam (Kelly, *B.* 11, 2222). Conc. KOH produces glycerin.

Nitrile $(CH_2Cl)_2C(OH).CN$. From *s*-di-chloro-acetone (50 g.) by digesting with HCy (20 g.), a little water, and alcohol 8 c.c.

Tri-chloro-oxy-isobutyric acid $CCl_3.CMe(OH).CO_2H$. From tri-chloro-acetone by successive treatment with HCy and HCl (Bischoff, *B.* 8, 1339). Syrup.

TRI-CHLORO-DI-OXY-DI-CYMYL-ETHANE $C_{22}H_{27}Cl_3O_2$ *i.e.* $CCl_3.CH(C_{10}H_{12}OH)_2$. [194°]. From thymol (2 mol.), chloral (1 mol.) and conc. H_2SO_4 diluted with HOAc (Jaeger, *B.* 7, 1197; *C. J.* 31, 262). Monoclinic needles (containing HOEt). Insol. water. Alcohol and zinc-dust form $CH_3CH(C_{10}H_{12}OH)_2$ and $CH_2:C(C_{10}H_{12}OH)_2$.

CHLORO-OXY-ETHYL-AMIDO-PHENYL-ETHANE $CCl_3.CH(OH).C_6H_4NHEt$. [98°]. From chloral hydrate and ethyl-aniline (Boessneck, *B.* 21, 782).

Nitrosamine $C_{10}H_{11}Cl_3N(NO)$ [138°].

(*Py.* 3:1:2)-CHLORO-OXY-ETHYL-QUINOLINE

. [248°]. Formed by the action of PCl_5 upon aniline ethyl-malonate under benzene. Colourless needles. M. sol. alcohol (Kiliani, *B.* 20, 1235).

TRI-CHLORO-OXY-ETHYL-SUCCINIC ACID ***Lactone.*** $CCl_3.CH.CH(CO_2H).CH_2.CO.O$. *Tri-chloro-methyl-peraconic acid.* [97°]. From chloral, sodium succinate and Ac_2O (Fittig, *B.* 20, 3179). Converted by baryta into barium isocitrate.

DI-CHLORO-DI-OXY-HEXANE $C_6H_{12}Cl_2O_2$ *i.e.* $CH_2Cl.CH(OH).CH_2.CH_2.CH(OH).CH_2Cl$. (?) S.G. ¹ 1·4. From diallyl and aqueous HOCl in the cold (Henry, *B.* 7, 416; *Z.* [2] 5, 479). Oil. Potash converts it into diallyl dioxide whence baryta-water produces the anhydride of tetra-oxy-hexane $C_6H_{12}O_3$ (Przibytek, *Bl.* [2] 45, 248).

Di-chloro-tetra-oxy-hexane *v.* MANNITE.

DI-CHLORO-DI-OXY-HEXINOIC ACID $C_6H_6Cl_2O_4$ *i.e.* $CH_2Cl.C(OH):CCl.C(OH):CH.CO_2H$ (?). *Di-chloro-di-oxy-amenyl carboxylic acid.* [177°]. From the following by sodium amalgam (Hantzsch, *B.* 20, 2789). Lustrous prisms. Conc. aqueous NaOH forms $C_6H_3ClO_4Na_2$ 6aq which crystallises in canary yellow needles and is converted by HCl into $C_5H_5ClO_2$ [97°], which forms a salt NaA' 3aq.—NH_4A'. [185°].

Acetyl derivative [134°].

Tri-chloro-di-oxy-hexinoic acid $C_6H_5Cl_3O_4$ *i.e.* $CH_2Cl.C(OH):CCl.C(OH):CCl.CO_2H$ (?) [177°]. Formed, together with tri-chloro-phenol, by passing chlorine into an alkaline solution of phenol (Hantzsch, *B.* 20, 2789). The yield is 50 p.c. Needles (from water); or monoclinic crystals (containing 4aq). Decomposed by conc. aqueous KOH.—NH_4A' 2aq: trimetric prisms, sl. sol. water.

Methyl ether MeA'. [126°].

Di-acetyl derivative $C_6H_3Ac_2Cl_3O_4$. [188°–192°].

CHLORO-DI-OXY-INDONAPHTHENE

or

$C_6H_4\left\langle\begin{matrix}CO\\CCl\end{matrix}\right\rangle C(OH)$. *Phenylene-chloro-oxy-acetylene-ketone.* [114°]. Formed by the action of acids or alkalis upon the amides

C:NR or

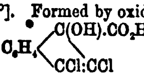
$C_6H_4\left\langle\begin{matrix}CO\\CCl\end{matrix}\right\rangle C:NHR$, which are obtained by the action of amines upon di-chloro-oxy-indonaphthene (*q.v.*),

$C_6H_4\left\langle\begin{matrix}CO\\CCl\end{matrix}\right\rangle CCl$. It is reconverted into these amides by the action of amines (Zincke, *B.* 20, 1271). White glistening plates (from dilute alcohol), or small compact crystals (from petroleum-spirit). Dissolves in aqueous alkalis with a red colour. By PCl_5 it is converted into the compound

(*In.* 3:1:2)-Di-chloro-oxy-indonaphthene

$C_6H_4\left<\substack{CCl\\|\\CCl}\right>CO$. [125°]. Formed by the action of PCl_5 upon chloro-di-oxy-indonaphthene $C_6H_4\left<\substack{C(OH)\\CCl}\right>CO$. Glistening plates (from dilute alcohol) (Zincke, *B.* 20, 1272).

(*In.* 3:2:1)-Di-chloro-oxy-indonaphthene $C_6H_4\left<\substack{CO\\CCl}\right>CCl$. *Phenylene-di-chloro-acetylene-ketone.* [90°]. Formed by oxidation of the carboxylic acid



$C_6H_4\left<\substack{C(OH).CO_2H\\CCl:CCl}\right.$ (from di-chloro-(β)-naphthoquinone) with CrO_3. Small yellow or long glistening golden needles. Very volatile with steam. It has some of the characteristics of a quinone. With aromatic bases it forms coloured compounds. Reacts with hydroxylamine and with phenylhydrazine. With halogens it yields colourless addition-products. It is not affected by $SnCl_2$ or by PCl_5.

Methyl-amide $C_6H_4\left<\substack{CO\\CCl}\right>C.NHMe$ or

$C_6H_4\left<\substack{C(OH)\\|\\CCl}\right>C:NMe$: [195°]; long dark-red needles, sol. hot alcohol and acetic acid, sl. sol. benzene.

Di-methyl-amide $C_6H_4:C_2ClO.NMe_2$: [140°]; long red needles or thick tables.—$B'_2H_2Cl_2PtCl_4$: yellow crystalline pp.

Anilide $C_6H_4:C_2ClO.NHPh$: [204°]; slender deep-red needles; dissolved in warm dilute alkalis without decomposition.

Oxim $C_6H_4\left<\substack{C(NOH)\\CCl}\right>CCl$: [120°]; long yellow needles; v. sol. warm alcohol and acetic acid (Zincke, *B.* 20, 1265).

Di-chloride $C_6H_4\left<\substack{CO\\CCl_2}\right>CCl_2$. [108°]. Converted by aqueous NaOH into tri-chloro-vinyl-benzoic acid [163°] (Zincke a Fröhlich, *B.* 20, 2053).

Di-bromide $C_6H_4\left<\substack{CO\\CClBr}\right>CClBr$. [114°], and, when rapidly heated, [c. 128°]. Converted by aqueous NaOH into di-chloro-bromo-vinyl-benzoic acid $CClBr:CCl.C_6H_4.CO_2H$ [174°].

Chloro-oxy-indonaphthalene dichloride $C_6H_4\left<\substack{CO\\CHCl}\right>CCl_2$. [59°]. From the dihydride of tri-chloro-di-oxy-indonaphthene carboxylic acid and dilute CrO_3Aq (Zincke, *B.* 20, 2890). Thick needles (from alcohol). Converted by alkalis into di-chloro-vinyl-benzoic acid.

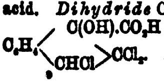
DI-CHLORO-DI-OXY-INDONAPHTHENE CARBOXYLIC ACID

$C_6H_4\left<\substack{C(OH)CO_2H\\CO}\right>CCl_2$. [139°]. Formed by dissolving the hydrate of tetra-chloro-(β)-naphthoquinone in dilute Na_2CO_3Aq and ppg. with an acid (Zincke, *B.* 21, 497). Thick needles (containing aq) (from water). V. sol. alcohol, benzene, and HOAc. CrO_3 gives $C_6H_4\left<\substack{CO\\CO}\right>CCl_2$ [124°].

Methyl ether MeA' [124°] large oblique crystals.

Acetyl derivative $C_{10}H_3AcCl_2O_4$. [126°]. Prisms.

Tri-chloro-oxy-indonaphthene carboxylic acid. *Dihydride* $C_{10}H_7Cl_3O_3$ *i.e.*



$C_6H_4\left<\substack{C(OH).CO_2H\\CHCl}\right>CCl_2$. From the dihydride of di-chloro-(β)-naphthoquinone

$C_6H_4\left<\substack{CO.CO\\|\\CHCl.CCl_2}\right.$ and dilute NaOH (Zincke a. Fröhlich, *B.* 20, 2894). Liquid.

Methyl ether MeA'. [150°].

Acetyl derivative of the methyl ether $C_{10}H_5MeAcCl_3O_3$. [116°].

DI-CHLORO-OXY-METHANE SULPHINIC ACID $CCl_2(OH)SO_2H$. Unstable deliquescent needles.

Salt.—A'K: Trimetric plates. From KCy and aqueous or alcoholic trichloro-methane sulphochloride (*q.v.*): $CCl_3.SO_2Cl + KCy + H_2O = CyCl + HCl + CCl_2(OH).SO_2K$. Boiled with potash it forms KCl and K_2SO_4 (Loew, *Z.* 1868, 518; McGowan, *J. pr.* [2] 30, 288).

DI-CHLORO-OXY-METHANE SULPHONIC ACID.

Chloride.—$CCl_2(OH)SO_2Cl$. From PCl_5 and $CCl_2(OH)SO_2K$ (McGowan, *J. pr.* [2] 30, 289).

Anilide.—$CCl_2(OH)SO_2NPhH$. Rhombohedra. From aniline and the above chloride.

TRI-ω-CHLORO-α-OXY-METHYL-AMIDO-PHENYL-ETHANE $CCl_3.CH(OH)C_6H_4NHMe$. [112°]. From chloral hydrate and methyl-aniline (Boessneck, *B.* 21, 782).

Nitrosamine $CCl_3.CH(OH).C_6H_4NMeNO$. [118°]. Needles.

Tri-α-chloro-α-oxy-di-methyl-amido-benzene $CCl_3.CH(OH).C_6H_4NMe_2$. Formed by condensation of chloral hydrate with di-methyl-aniline in presence of $ZnCl_2$ (Knöfler a. Boessneck, *B.* 20, 3193).

(*Py.* 3:1)-CHLORO-OXY-(*B.* 4)-METHYL-(*Py.* 2)-ETHYL-QUINOLINE

$C_6H_3Me\left<\substack{C(OH)=CEt\\|\\N=\!=\!=CCl}\right.$

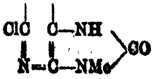
α-Chloro-β-ethyl-γ-oxy-o-toluquinoline. [225°]. Formed by the action of PCl_5 upon *o*-toluidine ethyl-malonate under benzene. Silky needles (from alcohol) (Kiliani, *B.* 20, 1233).

CHLORO-DI-OXY-METHYL-PURIN.

Methyl ethyl derivative $C_5N_4(CH_3)(OMe)(OEt)Cl$ (?) *Ethoxy-chloro-oxy-di-methyl-purin.* [160°]. Granular crystals. Formed by the action of a solution of NaOH in 50 p.c. alcohol on di-chloro-methoxy-methyl-purin. By HCl at 130° it is converted into tri-oxy-di-methyl-purin (di-methyl-uric acid). By HI it is reduced to di-oxy-di-methyl-purin (Fischer, *B.* 17, 335).

Di-ethyl derivative $C_5(CH_3)(OEt)_2ClN_4$. Formed by heating tri-chloro-methyl-purin with alcoholic NaOH (Fischer, *B.* 17, 332). Fine felted needles. Heated with HCl at 130° it gives methyl-uric acid (tri-oxy-methyl-purin).

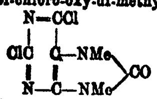
Di-chloro-oxy-methyl-purin $C_6H_4ON_4Cl_2$ *i.e.* $C_5(CH_3)(OH)Cl_2N_4$ probably



$$\begin{matrix} & N=CCl & \\ & |\quad\ \ | & \\ ClC & C-NH & \\ \| \quad & \| \quad\ \ & >CO \\ N= & C-NMe & \end{matrix}$$

[274°]. Obtained by heating methyl-uric acid with PCl_5 and $POCl_3$ at 130° (Fischer, *B.* 17, 330, 1786). Fine white needles. Very stable body, volatilising without decomposition and not being attacked by HNO_3 or by $KClO_3$ and HCl. By HI it is reduced to oxy-methyl-purin.

Di-chloro-oxy-di-methyl-purin $C_7H_6OCl_2N_4$ *i.e.*



$$\begin{array}{lll} \text{N}=\text{CCl} & & \\ |\qquad | & & \\ \text{ClC}\quad \text{C}-\text{NMe} & & \\ \|\qquad \| & >\text{CO} & \\ \text{N}-\text{C}-\text{NMe} & & \end{array}$$

or $C_5N_4(CH_3)(OMe)Cl_2$ [183°]. *Di-chloro-methoxy-methyl-purin.* Formed by heating the lead compound of di-chloro-oxy-methyl-purin with methyl iodide (Fischer, *B.* 17, 334, 1787). Fine colourless needles. Insol. alkalis. By HI it is reduced to methoxy-methyl-purin.

(*Py.* 4, 3) - **CHLORO-OXY - (B. 2) - METHYL-QUINOLINE** $C_9H_5CH_3NOCl$ *i.e.*

$$\begin{array}{l}\text{CMe:CH.C.CH:CH}\\ |\qquad\qquad \|\qquad\ \ |\\ \text{CH : CH.C:NCl.CO}\end{array}$$

Chloro-methyl-pseudocarbostyril. [121°]. Formed by treating a solution of (*B.* 2) methylquinoline in boric acid with bleaching powder solution (Emhorn a. Lauch, *A.* 248, 358). White needles (from acetic ether).

Reactions.—1. Boiled with NaOHAq (*B.* 2)-methyl-carbostyril [228°] is obtained.—2. Yields an isomeride [281°] on boiling with alcohol.

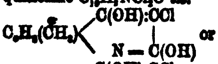
(*Py.* 1,3,4)-**Chloro-oxy-methyl-quinoline**

$$C_6H_4\left\langle\begin{array}{l}\text{CCl:CH}\\ \qquad\ \ |\\ \text{NMe.CO}\end{array}\right.$$

[117·5°]. From (γ)-chloro-carbostyril, MeI, and alcoholic NaOH (Friedländer a. Müller, *B.* 20, 2009). Hair-like needles (from MeOH).

(*Py.*)-**Chloro-di-oxy-(B. 2)-methyl-quinoline** *Di-ethyl derivative* $C_6H_3(CH_3)NC_3Cl(OEt)_2$. [71°]. Formed by heating (*Py.* 1:2:3)-tri-chloro-(*B.* 2)-methyl-quinoline with a solution of sodium in absolute alcohol at 100°–130°. Long colourless needles (Rügheimer a. Hoffmann, *B.* 18, 2982).

(*Py.* 2:3:1) - **Chloro - di - oxy-(B. 4) - methyl-quinoline** $C_{10}H_8NCl_2O$ *i.e.*



$$C_6H_3(CH_3)\left\langle\begin{array}{l}\text{C(OH):CCl}\\ \qquad\qquad |\\ \quad \text{N}=\text{C(OH)}\end{array}\right.$$

or

$$C_6H_3(CH_3)\left\langle\begin{array}{l}\text{C(OH):CCl}\\ \qquad\quad\ \ |\\ \text{NH}-\text{CO}\end{array}\right.$$

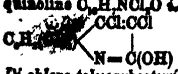
Chloro-oxy-tolucarbostyril. [277°]. Formed by heating (*Py.* 2:3:1)-di-chloro-oxy-(*B.* 4)-methyl-quinoline with dilute HCl at 160°. Large plates or tables. V. sol. acetic acid, sl. sol. alcohol, insol. water. Dissolves in acids and alkalis (Rügheimer a. Hoffmann, *B.* 18, 2986).

(*Py.* 1)-**Chloro-(B. 2)-oxy-methyl-quinoline.** *Methyl derivative*

$$\begin{array}{l}\text{C(OMe):CH.C.CCl.CH}\\ |\qquad\qquad\quad \|\quad\ \ |\\ \text{CH}=\text{CH.C.N.CMe}\end{array}$$

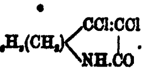
[100°]. (c. 296°). From the corresponding $C_9H_4Me(OH)(OMe)N$ by $POCl_3$ (Conrad a. Limpach, *B.* 21, 1649). Silky prisms.

(*Py.* 1:2:3) - **Di - chloro - oxy - (B. 2) - methyl-quinoline** $C_{10}H_7NCl_2O$ *i.e.*



$$C_6H_3(CH_3)\left\langle\begin{array}{l}\text{CCl:CCl}\\ \qquad\ \ |\\ \text{N}=\text{C(OH)}\end{array}\right.$$

or



$$C_6H_3(CH_3)\left\langle\begin{array}{l}\text{CCl:CCl}\\ \qquad\quad |\\ \text{NH.CO}\end{array}\right.$$

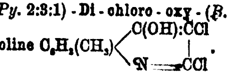
Di-chloro-tolucarbostyril. [292°]. Obtained by heating (*Py.* 1:2:3)-tri-chloro-(*B.* 2)-methyl-quinoline with dilute HCl at 180°. Small crystals. Sol. benzene and acetic acid, sl. sol. alcohol and ether, insol. water. Has both weak basic and weak acid properties (Rügheimer a. Hoffmann, *B.* 18, 2981).

(*Py.* 1:2:3) - **Di - chloro - oxy - (B. 4) - methyl-quinoline**

$$C_6H_3(CH_3)\left\langle\begin{array}{l}\text{CCl:CCl}\\ \qquad\ \ |\\ \text{N : C(OH)}\end{array}\right.$$

Di-chloro-tolucarbostyril. [288°]. Formed by heating (*Py.* 1:2:3)-tri-chloro-(*B.* 4)-methyl-quinoline with dilute HCl at 180°. Small white needles (from acetic acid). Sublimes in needles. Sl. sol. alcohol, insol. water (Rügheimer a. Hoffmann, *B.* 18, 2985).

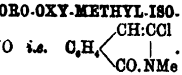
(*Py.* 2:3:1) - **Di - chloro - oxy - (B. 4) - methyl-quinoline**



$$C_6H_3(CH_3)\left\langle\begin{array}{l}\text{C(OH):CCl}\\ \qquad\qquad |\\ \text{N}=\text{CCl}\end{array}\right.$$

[245°]. Formed by the action of PCl_5 upon the acid malonate of *o*-toluidine in presence of cold benzene. Needles. Sl. sol. alcohol and acetic acid, nearly insol. water. Decomposes alkaline carbonates (Rügheimer a. Hoffmann, *B.* 18, 2983).

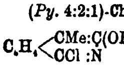
(*Py.* 2:4:3) - **CHLORO-OXY-METHYL-ISO-QUINOLINE** $C_{10}H_8ClNO$ *i.e.*



$$C_6H_4\left\langle\begin{array}{l}\text{CH:CCl}\\ \qquad\quad |\\ \text{CO.NMe}\end{array}\right.$$

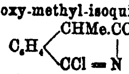
[112°]. Formed by methylation of (*Py.* 2:4)-chloro-oxy-isoquinoline [220°]. Long needles. V. sol. ether, benzene, chloroform, and hot alcohol (Gabriel, *B.* 19, 2361).

(*Py.* 4:2:1)-**Chloro-oxy-methyl-isoquinoline**



$$C_6H_4\left\langle\begin{array}{l}\text{CMe:C(OH)}\\ \text{CCl :N}\end{array}\right.$$

or



$$C_6H_4\left\langle\begin{array}{l}\text{CHMe.CO}\\ \qquad\qquad |\\ \text{CCl}=\text{N}\end{array}\right.$$

[224°]. Needles (from acetic acid). Sol. aqueous alkalis. Formed as a by-product of the reaction of $POCl_3$ upon the imide of phenyl-methyl-acetic-*o*-carboxylic acid

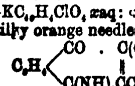
$$C_6H_4\left\langle\begin{array}{l}\text{CHMe}-\text{CO}\\ \qquad\qquad |\\ \text{CO}-\text{NH}\end{array}\right.$$

(Gabriel, *B.* 20, 2504).

CHLORO-OXY-(α)-NAPHTHOQUINONE $C_{10}H_5ClO_2$ *i.e.* $C_{10}H_4Cl(OH)O_2$. *Chloro-naphthalic acid.* [above 200°]. Formed by boiling chloro-naphthalene tetrachloride with HNO_3 (Laurent, *A.* 35, 293). Formed also by boiling di-chloro-naphthoquinone with alcoholic KOH (Graebe, *A.* 149, 14; P. a. E. Depouilly, *Bl.* [2] 4, 10); and by boiling the alkylamides of chloro-(α)-naphthoquinone with acids or aqueous KOH. Yellow needles; may be sublimed. Insol. water, m. sol. alcohol and ether. HNO_3 oxidises it to phthalic and oxalic acids. Turned red by alkalis. Distillation with PCl_5 gives penta-chloro-naphthalene.

Salts.—$KC_{10}H_4ClO_3$ *x*aq: crimson needles.—BaA'_2 aq: silky orange needles.

Imide



$$C_6H_4\left\langle\begin{array}{l}\text{CO . C(OH)}\\ \qquad\qquad \|\\ \text{C(NH).CCl}\end{array}\right.$$

[c. 260°]. Formed by the action of alcoholic NH_3 upon a hot alcoholic solution of chloro-(β)-naphthoquinone. Dark metallic plates. Sl. sol. alcohol and acetic acid. Dissolves in dilute NaOH with a dark-violet colour. Long boiling with HCl yields chloro-oxy-(α)-naphthoquinone (Zincke, *B.* 19, 2499).

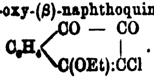
Anilide $C_6H_4\left<\begin{array}{l}CO—C(OH)\\ \qquad\quad\Vert\\ C(NPh).CCl\end{array}\right.$. [258°]. Dark metallic plates. Formed by the action of aniline upon a hot alcoholic solution of chloro-(β)-naphthoquinone (Zincke, *B.* 19, 2499).

('β')-Chloro-oxy-(α)-naphthoquinone $C_{10}H_4Cl(OH)O_2$. [205° uncor.]. Formed by boiling ('β')-di-chloro-(α)-naphthoquinone $C_6H_3Cl\left<\begin{array}{l}CO.CCl_2\\ CO.CH\end{array}\right.$ with alkalis. Felted yellow needles. V. sol. alcohol, ether, &c., sl. sol. water. Sublimable. The alkali-salts are v. sol. water with a deep red colour; the Ca and Ba salts are sparingly soluble.—A'_2Cu: insoluble red pp.—A'_2Pb: yellowish red pp.

Anilide $C_{10}H_4Cl(NHPh)O_2$: [155° uncor.]. Formed by boiling an alcoholic solution of ('β')-di-chloro-naphthoquinone with aniline. Dark violet crystals. V. sol. acetic acid, sl. sol. alcohol.

o-Toluide $C_{10}H_4Cl(NHC_7H_7)O$: [175° uncor.].

p-Toluide $C_{10}H_4Cl(NHC_7H_7)O_2$: [164° uncor.] (Claus a. Müller, *B.* 18, 3074).



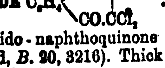
Chloro-oxy-(β)-naphthoquinone. ***Ethyl derivative*** $C_6H_4\left<\begin{array}{l}CO — CO\\ \qquad\quad\vert\\ C(OEt):CCl\end{array}\right.$. [149°]. From tetra-chloro-(α)-naphthol $C_6H_4\left<\begin{array}{l}CO.CCl_2\\ \qquad\vert\\ CCl:CCl\end{array}\right.$ and alcoholic KOH (Zincke, *B.* 21, 1027). Orange needles.

Propyl derivative $C_{10}H_4ClO_2(OPr)$. [190°]. Formed in like manner, using propyl alcohol.

Tri-chloro-oxy-(α)-naphthoquinone $C_{10}H_2Cl_3(OH)O_2$. [235° uncor.]. Formed by boiling tetra-chloro-(α)-naphthoquinone with alcoholic KOH. Yellow needles. Sublimable. V. sol. alcohol, ether, &c., sl. sol. water. Its salts are deep red. By treatment with aniline it gives an anilide [180° uncor.], which forms coppery needles. Sol. hot alcohol, acetic acid, and ether, sl. sol. cold alcohol, insol. water.

The corresponding *o*- and *p*-toluidine derivatives melt at [205°] and [203°] uncor. respectively (Claus, *B.* 19, 1141).

Tetra-chloro-oxy-(α)-naphthoquinone $C_6Cl_4\left<\begin{array}{l}CO.C(OH)\\ \qquad\Vert\\ CO.C(OH)\end{array}\right.$. [265° uncor.]. Formed by dissolving penta-chloro-(α)-naphthoquinone in alcoholic KOH, and precipitating the acid by HCl. Sublimes in yellow needles. The alkaline salts are v. sol. water, the Ag, Pb, Cu, &c. salts are red pps. (Claus a. Wenzlik, *B.* 19, 1168).



DI-CHLORO-DI-OXY-(α)-NAPHTHOQUINONE DIHYDRIDE $C_6H_4\left<\begin{array}{l}CO.C(OH)_2\\ \qquad\vert\\ CO.CCl_2\end{array}\right.$. [105°]. From chloro-amido-naphthoquinone and Cl (Zincke a. Gerland, *B.* 20, 3216). Thick needles. Converted by alkalis into a compound [129°] which may be oxidised to another [125°].

CHLORO-OXY-NAPHTHOQUINONE SULPHONIC ACID (?) $C_{10}H_5ClSO_6$ *i.e.* $C_{10}H_3ClO_2(OH)(SO_3H)$. From naphthalene, $KClO_3$, and H_2SO_4 (Hermann, *A.* 151, 63; *Z.* [2] 4, 551). Amorphous mass, m. sol. water, v. sol. alcohol and ether. When boiled with water it exchanges Cl for OH. The K salt is a red dye.

(2, 3 ?)-Chloro-oxy-(α)-naphthoquinone (3')-sulphonic acid $C_{10}H_3ClO_2(OH)(SO_3H)$. [211°]. From di-chloro-naphthoquinone sulphonic acid by displacing Cl by OH (Claus, *J. pr.* [2] 37, 184). Crystals; v. sol. water, sl. sol. alcohol, insol. ether.

Salts.—The normal salts are yellowish-red, the basic salts are dark red.—Na_2A'' 2aq.—BaA'' 2aq.—PbA''.—Ag_2A''aq.

Phenyl derivative $C_{10}H_3(SO_3H)Cl(OPh)O_2$. [121°]. Formed by the addition of phenol and a small quantity of potash to a hot solution of the sodium salt. $C_{10}H_3(SO_3Na)Cl(OPh)O_2(PhOH)$.—$BaA'_2$2PhOH. Small needles (from water). — AgA'PhOH. Needles. V. sol. hot, sl. sol. cold, water.

Acetyl derivative $C_{10}H_3(SO_3H)Cl(OAc)O_2$. Salts.—$NaA'$: bright yellow needles. The Ag, Pb and Ba salts form double salts with the precipitant.

CHLORO-OXY-NICOTINIC ACID *v.* **CHLORO-OXY-PYRIDINE CARBOXYLIC ACID.**

DI-CHLORO-DI-OXY-OCTANE $C_8H_{14}Cl_2(OH)_2$. Formed by the action of ClOH on CH_2:CMe.CH_2.CH_2.CMe:CH_2 (Przybitek, *B.* 20, 3239).

DI-CHLORO-OXY-OCTOIC ACID $C_8H_{14}Cl_2O_3$ *i.e.* $(C_3H_6Cl)_2C(OH).CO_2H$. Formed by the union of HCl with $(C_3H_5)_2C(OH).CO_2H$ obtained from oxalic ether and zinc allyl (Schatzky, *J. R.* 17, 73). Syrup.

DI-CHLORO-HEXA-OXY-DIPHENYL.

Tetra-methyl ether. $C_{16}H_{16}Cl_2O_6$ *i.e.* $C_{12}H_2Cl_2(OH)_2(OMe)_4$. *Di-chloro-hydrocœrulignon.* [220°]. From its acetyl derivative and alcoholic KOH (Hayduck, *B.* 9, 929). Small plates (from alcohol). M. sol. hot alcohol.—$C_{16}H_{14}K_2Cl_2O_6$: needles.—BaA''.

Di-acetyl-derivative $C_{12}H_2Cl_2(OAc)_2(OMe)_4$. [172°]. From di-acetyl-cœrulignon and PCl_5. Small prisms.

Hexa-methyl ether $C_{12}H_2Cl_2(OMe)_6$. From $C_{12}H_4(OMe)_6$ and Cl (Ewald, *B.* 11, 1624). Needles (from alcohol).

Tetra-chloro-di-oxy-diphenyl $C_{12}H_6Cl_4O_2$ *i.e.* $C_6H_2Cl_2(OH).C_6H_2Cl_2(OH)$. [233° uncor.]. From di-oxy-diphenyl in HOAc and Cl (Magatti, *B.* 13, 227). Needles (from dilute alcohol). Fuming HNO_3 gives dark red insoluble scales of $\begin{array}{l}C_6H_2Cl_2.O\\ \vert\qquad\quad\vert\\ C_6H_2Cl_2.O\end{array}$.

Octo-chloro-di-oxy-diphenyl $C_{12}Cl_8(OH)_2$. *Per-chloro-diphenol.* [234°]. Prepared by heating per-chloro-diphenyl with alcoholic NaOH at 150° (Weber a. Söllscher, *B.* 16, 883). Quadratic tables. Sol. benzene and alkalis.

Di-methyl ether $C_{12}Cl_8(OMe)_2$: [226°]; long white needles.

Di-acetyl derivative $C_{12}Cl_8(OAc)_2$: [194°]; pointed crystals.

CHLORO-OXY-PHENYL-CARBAMIC ACID.

Anhydride $C_6H_3Cl\left<\begin{array}{c}NH\\ O\end{array}\right>CO$. *Carbonyl-chloro-amido-phenol.* [193°]. Formed by boiling with alcohol the product $(C_6H_3Cl\left<\begin{array}{c}NCl\\ O\end{array}\right>CO)$ of the action of bleaching-powder on $C_6H_4<\substack{NH\\O}>CO$ (Jacoby, *J. pr.* [2] 37, 32). Plates (from water, HOAc, and benzene). Sl. sol. hot water. May be sublimed.

Eso-ν-di-chloro-oxy-phenyl-carbamic acid. ***Anhydride*** $C_6H_2Cl<\substack{NCl\\O}>CO$. (α)-*Carbonyl chloro-phenol chlorimide.* [119°]. From the preceding and chlorine-water (Jacoby, *J. pr.* [2] 37, 40). Plates; m. sol. chloroform and benzene. Converted by heat into the following isomeride. Converted into the preceding body by boiling with alcohol, ether, water, aniline, di-methyl-aniline, and phenyl-hydrazine.

Di-chloro-oxy-phenyl-carbamic acid. ***Anhydride*** $C_6H_2Cl_2<\substack{NH\\O}>CO$. (α)-*Carbonyl-di-chloro-amido-phenol.* [270°]. The chief product of the action of heat on the preceding, the following isomeride being also formed (J.). Prisms (from alcohol). May be sublimed.

Di-chloro-oxy-phenyl-carbamic acid. ***Anhydride*** $C_6H_2Cl_2<\substack{NH\\O}>CO$. (β)-*Carbonyl-di-chloro-amido-phenol.* [214°]. Formed as above. Needles; v. e. sol. alcohol, ether, and HOAc; m. sol. water. Sublimes in needles.

Tri-chloro-oxy-phenyl-carbamic acid. ***Anhydride*** $C_6H_2Cl_2<\substack{NCl\\O}>CO$. (α)-*Carbonyl-di-chloro-phenol chlorimide.* [c. 147°]. From $C_6H_2Cl<\substack{NCl\\O}>CO$ and a solution of bleaching-powder (Jacoby, *J. pr.* [2] 37, 46).

Tri-chloro-oxy-phenyl-carbamic acid. ***Anhydride*** $C_6H_2Cl_2<\substack{NCl\\O}>CO$. [89°]. (β)-*Carbonyl-di-chloro-phenol chlorimide.* From $C_6H_2Cl_2<\substack{NH\\O}>CO$ in HOAc by adding a solution of bleaching-powder (J.). Needles; sol. water.

Tri-chloro-oxy-phenyl-carbamic acid. ***Anhydride*** $C_6HCl_3<\substack{NH\\O}>CO$. *Carbonyl-tri-chloro-amido-phenol.* [262°]. Formed from $C_6H_4<\substack{NH\\O}>CO$ in HOAc by chlorination and subsequent decomposition of the product by boiling alcohol (J.). Needles, sl. sol. alcohol, HOAc, and water. Sublimes in plates.

Tetra-chloro-oxy-phenyl-carbamic acid. ***Anhydride*** $C_6Cl_4<\substack{NH\\O}>CO$. *Carbonyl-tetra-chloro-amido-phenol.* [c. 229°]. Formed by heating $C_6HCl_3<\substack{NCl\\O}>CO$ which is obtained by treating a solution of the preceding in HOAc with bleaching-powder (Jacoby, *J. pr.* [2] 37, 48). White crystalline sublimate; sl. sol. water; m. sol. alcohol and HOAc; v. sol. ether and benzene. Converted by bleaching-powder solution into $C_6Cl_4<\substack{NCl\\O}>CO$ whence it is regenerated by boiling with alcohol.

TRI-CHLORO-DI-OXY-DI-PHENYL-ETHANE $C_{14}H_{11}Cl_3O_2$ *i.e.* $CCl_3.CH(C_6H_4OH)_2$. [202°]. From phenol, chloral, H_2SO_4, and HOAc at 0° (ter Meer, *B.* 7, 1201). Small crystals; v. sol. alcohol and ether. Alcohol and zinc-dust give $CH_2{:}C(C_6H_4OH)_2$.

Di-acetyl derivative $CCl_3.CH(C_6H_4OAc)_2$. [138°]. Needles.

DI-CHLORO-OXY-PHENYL-METHYL-PYRAZOLE $C_{10}H_8N_2OCl_2$ *i.e.* $Ph.N<\substack{CO—CCl_2\\N=CMe}>$. [61°]. Obtained by passing chlorine into oxy-phenyl-methyl-pyrazole dissolved in chloroform (Knorr, *A.* 238, 178). Crystalline mass, volatile with steam, insol. water and alkalis, sol. alcohol and ether. Reduced by Sn and HCl to oxy-phenyl-methyl-pyrazole.

β-CHLORO-(α)-OXY-PHENYL-PROPIONIC ACID $C_9H_9ClO_3$ *i.e.* $Ph.CH(OH).CHCl.CO_2H$ [104°]. From sodic cinnamate, sodic carbonate and chlorine (Glaser, *A.* 147, 80; 219, 183) or better, from potassic cinnamate and HClO (Erlenmeyer a. Lipp, *A.* 219, 184). Slender six-sided laminæ (containing aq). Melts, in the hydrated condition, at 80°. M. sol. cold water.

Reactions.—1. *Alkalis* form so-called β-oxy-phenyl-cinnamic acid which is probably the anhydride of αβ-di-oxy-phenyl-propionic acid

$C_6H_5.CH\overset{O}{\frown}CH.CO_2H$ (Erlenmeyer, *B.* 20, 2465), and αβ-di-oxy-phenyl-propionic acid.—2. *Sodium amalgam* forms β-oxy-phenyl-propionic acid.—3. Fuming HCl produces αβ-di-chloro-phenyl-propionic acid.—4. Boiling with Ac_2O gives α-chloro-cinnamic acid.

Salt.—AgA′: crystalline powder.

α-Chloro-β-oxy-phenyl-propionic acid $C_6H_5.CH(OH).CHCl.CO_2H$. From αβ-di-oxy-phenyl-propionic acid and HCl (Leschhorn, *Dissert. Wurzburg*, 1884). Formed also by the action of HCl on $C_6H_5.CH\overset{O}{\frown}CH.CO_2H$, which is obtained by treating the preceding acid with alkalis (Erlenmeyer, jun., *B.* 20, 2466).

Chloro-oxy-α-phenyl-propionic acid $C_9H_9ClO_3$. *Chloro-tropic acid.* [130°]. From atropic acid and aqueous ClOH (Ladenburg, *A.* 217, 110). Crystals; v. e. sol. water. Zinc-dust and iron filings in HOAc convert it into tropic acid.

(*Py.* 1:4:2)-**CHLORO-OXY-PHENYL-ISO-QUINOLINE** $C_{15}H_{10}ClNO$ *i.e.*

$$C_6H_4\left<\begin{matrix}CCl{:}CPh\\ \quad|\\ CO{:}NH\end{matrix}\right. \text{ or } C_6H_4\left<\begin{matrix}CCl : CPh\\ \qquad|\\ C(OH){:}N\end{matrix}\right. .$$

Chloro-isobenzalphthalimidine. [212°]. Formed by heating chloro-methoxy-phenyl-isoquinoline [76°] with fuming HCl at 100°. Silky needles. V. sol. benzene, chloroform, and acetic acid, m. sol. cold alcohol and ether (Gabriel, *B.* 19, 2358).

Methyl derivative $C_{16}H_{12}NOCl$ *i.e.*

$$C_6H_4\left<\begin{matrix}CCl : CPh\\ \qquad|\\ C(OMe){:}N\end{matrix}\right. .$$

[76°]. Formed by heating di-chloro-phenyl-isoquinoline with a solution of sodium in methyl alcohol at 100°. Colourless needles. V. sol. ether, chloroform, benzene, and acetic acid. Very weak base. By heating with fuming HCl at 100° it yields chloro-oxy-phenyl-isoquinoline (chloro-isobenzalphthalimidine) and methyl chloride (Gabriel, *B.* 19, 2357).

TETRA - CHLORO - DI - OXY - DI - PHENYL SULPHONE $C_{12}H_6Cl_4SO_4$ *i.e.* $SO_2(C_6H_2Cl_2.OH)_2$. [289°]. S.G. ^{15} 1·777. From $SO_2(C_6H_4.OH)_2$, $KClO_3$, and HCl (Annaheim, *A*. 172, 38; *B*. 9, 1150). Needles or prisms. Insol. water, v. sl. sol. cold alcohol.

DI - CHLORO - DI - OXY - DI - PHENYL - THIOUREA. *Di-methyl ether* $SC(NH.C_6H_3Cl(OMe))_2$. [153°]. From chloro-anisidine, alcohol, and CS_2. White needles, sol. alcohol and ether (Herold, *B*. 15, 1687).

CHLORO-OXY-PICOLINIC ACID *v*. CHLORO-OXY-PYRIDINE CARBOXYLIC ACID.

CHLORO-OXY-PROPANE SULPHONIC ACID $C_3H_7ClSO_4$ *i.e.* $CH_2Cl.CH(OH).CH_2.SO_3H$. From epichlorhydrin and Na_2SO_3 at 100° (Darmstädter, *A*. 148, 126). Syrup.—NaA′2aq: monoclinic crystals.—NaA′ aq: trimetric tables.—NaA′ ½aq (Pazschke, *J. pr.* [2] 1, 94).—CaA′$_2$ 6aq.—BaA′$_2$ aq. PbA′$_2$ 2aq.—AgA′ 3aq.

β-CHLORO-α-OXY-PROPIONIC ACID $CH_2Cl.CH(OH)CO_2H$. *Chloro-lactic acid.* [78°].

Formation.—1. From chloro-acetic aldehyde by treatment with HCN and HCl (Glinsky, *Z*. 1870, 515; Frank, *A*. 206, 344).—2. Together with its isomeride by the union of HOCl with acrylic acid in aqueous solution at 0° (Melikoff, *B*. 13, 2153).

Preparation.—Epichlorhydrin (5 g.) is heated with (20 g. of) nitric acid (S.G. 1·38) on a water bath until the odour of chloropicrin is perceived. The product is poured into water and extracted with ether. On evaporation this leaves an oil that solidifies over H_2SO_4 (v. Richter, *J. pr.* 128, 193).

Properties.—Flat, deliquescent prisms. V. sol. water, alcohol, and ether. Cannot be distilled. Moist Ag_2O converts it into glyceric acid. When heated with water it splits up into aldehyde, CO_2, and HCl (Erlenmeyer, *B*. 13, 309).

Salts.—CaA′$_2$ 3aq.—ZnA′$_2$ 3aq.—MnA′$_2$ 3aq. CuA′$_2$.—AgA′.

Methyl ether MeA′: (186°); liquid.

Ethyl ether EtA′. [37°]. (205°).

α-Chloro-β-oxy-propionic acid $CH_2OH.CHCl.CO_2H$.

Formation.—1. From glyceric acid and HCl (Werigo a. Melikoff, *B*. 12, 178).—2. From acrylic acid and HOCl.—3. By the action of water on αβ-di-chloro-propionic acid (Melikoff, *B*. 12, 2227).—4. From oxy-acrylic acid and HCl (Melikoff, *B*. 13, 273).

Properties.—Syrup. V. sol. water, alcohol, and ether. Converted by moist Ag_2O into glyceric acid, and by alcoholic KOH into oxy-acrylic acid. Conc. HCl forms, at 100°, αβ-di-chloro-propionic acid [50°]. Zinc and dilute H_2SO_4 reduce it to hydracrylic acid (Melikoff, *J. R.* 13, 164).

Salt.—ZnA′$_2$: hygroscopic gummy mass.

Di-chloro-oxy-propionic acid $CHCl_2.CH(OH).CO_2H$. [77°]. From di-chloro-acetic aldehyde, HCN, and HCl (Grimaux a. Adam, *B*. 10, 903; *Bl*. [2] 34, 29). Deliquescent tables; v. e. sol. water, alcohol, and ether. Reduces ammoniacal $AgNO_3$.

Ethyl ether EtA′. (220°). From the acid. Also from tri-chloro-oxy-propionic ether in alcoholic solution, by treatment with zinc, and HCl (Pinner a. Bischoff, *A*. 179, 88).

Tri-chloro-oxy-propionic acid $CCl_3.CH(OH).CO_2H$. *Tri-chloro-lactic acid.* [105°–110°]. From its nitrile by HCl (Pinner, *A*. 179, 79; *B*. 17, 1997). Prisms; sol. ether. Split up by alkalis into chloral and formic acid.

Reactions.—1. With strong aqueous NH_3 it gives glycosine.—2. With *hydroxylamine* it yields glyoxim.—3. With *phenyl-hydrazine* it yields glyoxal-di-phenyl-hydrazide.—4. With *urea* and a little water it gives acetylene-urea $C_4H_6N_4O_2$ *i.e.*

$\mathrm{OC}\!\left\langle\begin{array}{c}\mathrm{NH.CH.NH}\\ | \\ \mathrm{NH.CH.NH}\end{array}\right\rangle\!\mathrm{CO}$

(Pinner, *B*. 17, 1997).—5. Fusion with *urea* forms some uric acid (Horbaczewski, *M*. 8, 584).

Salts.—NH_4A'.—KA′: prisms.

Ethyl ether EtA′. [67°]. (c. 235°). Formed by heating chloralide with alcohol (Wallach, *A*. 193, 8).

Preparation.—Chloral-hydrate is converted into its cyanhydrin by mixing with strong HCN, and after 24 hrs. standing the mixture is digested on the water-bath for 4–6 hrs. and evaporated. The crystalline cyanhydrin is dissolved in one-third its weight of alcohol and HCl gas led into the boiling solution. When the reaction is complete the ether is precipitated by water, and solidifies on cooling; the yield is 90 p.c. of the theoretical (Pinner, *B*. 18, 754).

Properties. — Insol. water. Converted by alkalis into tartronic acid. Zinc and HCl reduce it, in alcoholic solution, to di-chloro-oxy-propionic acid.

Acetyl derivative $CCl_3.CH(OAc).CO_2H$. [65°].

Tri-chloro-ethylidene ether *v*. CHLORALIDE.

Tri-bromo-ethylidene ether

$\mathrm{CBr_3.CH}\!\left\langle\begin{array}{l}\mathrm{O.CO}\\ \mathrm{O}\end{array}\right\rangle\!\mathrm{CH.CCl_3}$

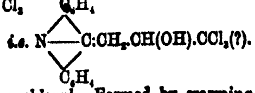
[149°] (Wallach, *A*. 193, 1).

Amide $CCl_3.CH(OH).CONH_2$. [96°]. From the nitrile, HOAc, and H_2SO_4 (Pinner a. Fuchs, *B*. 10, 1061). Slender needles; v. sol. cold water. Acetyl derivative $CCl_3.CH(OAc).CO.NH_2$. [95°].

Nitrile $CCl_3.CH(OH).CN$. [61°]. (c. 218°). From chloral and HCN (Hagemann, *B*. 5, 151; Pinner a. Bischoff, *A*. 179, 77; 17, 1997). Trimetric tables (from CS_2). V. sol. water, alcohol, and ether. *Reactions.*—1. Alkalis split it up into chloroform, HCy, and formic acid.—2. Ammonia forms di-chloro-acetamide. — 3. Heated with *urea* it yields tri-chloro-ethylidene-di-ureïde $CCl_3.CH(NH.CO.NH_2)_2$ as chief product, and biuret as a by-product (Pinner a. Lifschütz, *B*. 20, 2345).

Acetyl derivative $CCl_3.C(OAc).CN$. [31°]. (208°).

ω-TRI-CHLORO-β-OXY-(A.)-PROPYL-ACRIDINE $C_{16}H_{12}ONCl_3$ *i.e.*



$\mathrm{N}\begin{array}{c}\mathrm{C_6H_4}\\ \diagup\;\diagdown\\ \text{———}\\ \diagdown\;\diagup\\ \mathrm{C_6H_4}\end{array}\mathrm{C{:}CH_2.CH(OH).CCl_3}$ (?).

Methyl-acridine chloral. Formed by warming (*A*.)-methyl-acridine (60 g.) suspended in benzene (600 g.) with anhydrous chloral (70 g.); at 70°–75° the product separates as a sandy pp.; the yield is nearly theoretical. Yellow needles or prisms. Above 200° it is again resolved into methyl-acridine and chloral. Sl. sol. all ordinary solvents. *Its basic* properties are very slight. The solution in conc. H_2SO_4 has a splendid greenish-yellow fluorescence. By alkalis it is partially resolved into methyl-acridine and chloral, and partly converted into acridyl-acrylic acid $C_{13}H_8N.CH{:}CH.CO_2H$ whence $KMnO_4$ produces acridine-(*A.*)-aldehyde  $C_6H_4\left\langle\begin{matrix}C{-}CH.O\\ |\\ N\end{matrix}\right\rangle C_6H_4$ [140°] (Bernthsen a. Muhlert, *B.* 20, 1542).

DI-CHLORO-OXY-PYRIDINE $C_5H_2(OH)Cl_2N$ [178°]. Formed by heating the ethyl ether with HCl (Kœnigs a. Geigy, *B.* 17, 1834). Colourless crystals. V. sol. hot water.

Ethyl ether $C_5H_2(OEt)Cl_2N$: [31°]; white crystals; formed by heating tri-chloro-pyridine with sodium ethylate.

CHLORO-(γ)-OXY-PYRIDINE CARBOXYLIC ACID $C_5H_2ClN(OH)(CO_2H)$. *Chloro-oxy-picolinic acid.* S. 4 at 100°.

Preparation.—Comenamic acid (*q.v.*) is heated with PCl_5 (5 equivalents) in a sealed tube at 220°. The product is poured into water at 0°. The oil that separates is extracted with hot water and the extract evaporated to crystallisation. The crystals are dissolved in a little hot water and NH_3 is added: ammonic comenate separates and calcic chloride is then added to the filtrate. Calcic chloro-oxy-methyl pyridine carboxylate crystallises out slowly (Bellmann, *J. pr.* [2] 29, 3).

Properties.—Pointed needles (containing aq). Insol. cold water, ether, chloroform, and benzene. Sol. alcohol and acids.

Reactions.—1. Fe_2Cl_6 gives a brown pp. sol. excess.—2. $AgNO_3$ gives a bulky white pp. soon becoming granular.—3. Reduced by Sn and HCl to (γ)-oxy-pyridine carboxylic acid ((γ)-oxy-picolinic acid).

Salts.—B'HCl. Very soluble pointed needles. CaA'_2 aq. Got by adding $CaCl_2$ to a solution of the acid nearly neutralised by NH_3. M. sol. water.—  $C_5H_2ClN\left\langle\begin{matrix}O\\ CO_2\end{matrix}\right\rangle Ca$ ½aq. Got by adding $CaCl_2$ to a solution of the acid quite neutralised by NH_3.

Chloro-oxy-pyridine carboxylic acid $C_5H_2ClN(OH)CO_2H$. *Chloro-oxy-picolinic acid.* [c. 257°]. Obtained by heating penta-chloro-methyl-pyridine $C_5H_2Cl_2N.CCl_3$ with H_2SO_4 (Ost, *J. pr.* [2] 27, 257). Thick needles (containing aq). Reduced by HI in acetic acid to (β)-oxy-picolinic acid.

Salt.—CaA'_2 4aq.

Chloro-oxy-pyridine carboxylic acid $C_5H_2ClN(OH).CO_2H$. *Chloro-oxy-picolinic acid.* Obtained by the action of H_2SO_4 on penta-chloro-methyl-pyridine obtained by treating picolinic acid with PCl_5 (Seyfferth, *J. pr.* [2] 34, 244). Clusters of needles. Does not melt below 315°. Sl. sol. cold water. Does not combine with HCl.

Chloro-oxy-pyridine carboxylic acid $C_5H_2ClN(OH)CO_2H$. *Chloro-oxy-nicotinic acid.* [302°]. From nicotinic acid by successive treatment with PCl_5 and H_2SO_4. Monoclinic prisms (S.).

Di-chloro-oxy-pyridine carboxylic acid $C_5HCl_2N(OH)CO_2H$. ***Di-chloro-oxy-picolinic acid.*** [c. 282°].

Preparation.—By heating hexa-chloro-methyl-pyridine $C_5HCl_2N.CCl_3$ with (80 p.c.) H_2SO_4 (Ost, *J. pr.* [2] 27, 257).

Properties.—Felt-work of fine needles (containing aq) (from water), or else as small hard prisms. Decomposes about 282°. Not attacked by Sn and HCl or by aqueous HI. Reduced by HI in glacial acetic acid to (α)-oxy-picolinic acid.

Salts.—Mostly soluble, except the calcium salt, CaA'_2, which is but slightly soluble, although it is more soluble than the acid. Separates by spontaneous evaporation as silvery stars.

CHLORO-OXY-PYROTARTARIC ACID $C_5H_7ClO_5$. *Chloro-citramalic acid.* [100°].

Formation.—1. From citraconates and HClO (Carius, *A.* 126, 204).—2. From citra- or mesa-di-chloro-pyrotartaric acid by warming with water (Gottlieb, *A.* 160, 101; Morawski, *J. pr.* [2] 10, 68; 11, 466).—3. By passing chlorine into an aqueous solution of sodium mesaconate (Morawski, *J. pr.* [2] 12, 392).

Properties.—Trimetric crystals. Water at 120° converts it into di-oxy-pyrotartaric acid and acetone.

Salts.—BaA'' 4aq: monoclinic tables, v. sl. sol. cold water.—PbA'' 4aq.—Ag_2A''.

Chloro-oxy-pyrotartaric acid $C_5H_7ClO_5$. *Hydro-chloro-oxy-citraconic acid.* [162°]. From oxy-citraconic acid and fuming HCl at 120° (Morawski, *J. pr.* [2] 11, 443). Plates. Split up by bases into HCl and oxy-citraconic acid. Sodium amalgam reduces it to oxy-pyrotartaric acid *q.v.*

CHLORO-OXY-QUINOLINE C_9H_6NOCl *i.e.*  $C_6H_4\left\langle\begin{matrix}CH{:}CH\\ \quad\ \ |\\ N{:}COCl\end{matrix}\right.$. [112°]. Formed by the action of bleaching powder solution on the borate of quinoline (Einhorn a. Lauch, *A.* 243, 343). White prismatic needles. Sol. hot water, acetic ether, HOAc.

Reactions.—1. Boiled in an alkaline solution carbostyril is formed.—2. PCl_5 forms (*Py.* 3) chloro-quinoline. — 3. Boiled with alcohol *p*-chloro-carbostyril [263°] is formed.

(*B.* 2)-Chloro-(*Py.* 3)-oxy-quinoline  $\begin{matrix}CCl{:}CH.C.CH{:}CH\\ |\qquad\ \ \Vert\qquad |\\ CH{:}CH.C\,.\,N{:}C(OH)\end{matrix}$. ***p-Chloro-carbostyril.*** [263°]. Formed by treating the following body with alkalis, and, by intramolecular change, from the preceding body. When its alkaline solution mixed with NaOCl is treated with CO_2 the following body is ppd. $KMnO_4$ gives *p-chloro-isatin* [248°].

(*B.* 2, *Py.* 3)-Di-chloro-(*Py.* 3)-oxy-quinoline  $\begin{matrix}CCl{:}CH.C.CH{:}CH\\ |\qquad\ \ \Vert\qquad |\\ CH{:}CH.C\,.\,N{:}COCl\end{matrix}$. [115°] and [145°]. From (*B.* 2)-chloro-quinoline and bleaching powder (Einhorn a. Lauch, *A.* 243, 353). Plates (from HOAc) or needles (from EtOAc). Dimorphous. Boiling alkalis give chloro-carbostyril [263°].

Chloro-oxy-quinoline *v.* CHLORO-CARBOSTYRIL.

Tri-chloro-oxy-quinoline $C_9H_4Cl_3ON$. [200°]. Prepared by passing chlorine for 6 hours into a solution of quinoline in dilute acetic acid. The product is crystallised from alcohol. The yield is 15 p.c., most of the quinoline being recovered. Thin matted needles, sol. benzene, chloroform, and alcohol. Reduced by HI at 250° to oxy-quinoline, which is found to be (*Py.* 3)-oxy-quinoline (J. Rotheit, *J. pr.* [2] 29, 300).

(*Py.* 2:4)-CHLORO-OXY-ISOQUINOLINE C_9H_6ClNO *i.e.* $C_6H_4\left\langle\begin{array}{l}CH:CCl\\ \quad\quad |\\ C(OH):N\end{array}\right.$ or  $C_6H_4\left\langle\begin{array}{l}CH:CCl\\ \quad\quad |\\ CO.NH\end{array}\right.$. [220°]. Fine needles. V. sol. ordinary solvents. Dissolves in dilute NaOH. Formed as a by-product in the action of alcoholic KOH upon di-chloro-isoquinoline. Obtained by the action of dry HCl gas at c. 150° upon (*Py.* 2:4)-chloro-methoxy-isoquinoline  $C_6H_4\left\langle\begin{array}{l}CH{=\!=}CCl\\ \quad\quad\quad |\\ C(OMe):N\end{array}\right.$. On methylation with MeI and methyl alcoholic KOH, it is converted into (*Py.* 2:4:3)-chloro-oxy-methyl-isoquinoline  $C_6H_4\left\langle\begin{array}{l}CH:CCl\\ \quad\quad |\\ CO.NMe\end{array}\right.$, isomeric with the above chloro-methoxy-isoquinoline (Gabriel, *B.* 19, 2360).

Methyl derivative  $C_6H_4\left\langle\begin{array}{l}CH{=\!=}CCl\\ \quad\quad\quad |\\ C(OMe):N\end{array}\right.$. [74°]. Formed by heating di-chloro-isoquinoline with a solution of sodium in methyl alcohol, at 100°. Thick needles. V. sol. alcohol, ether, &c. By digestion with fuming HCl at 100° it is converted into the imide of phenyl-acetic-*o*-carboxylic acid  $C_6H_4\left\langle\begin{array}{l}CH_2.CO\\ \quad\quad |\\ CO.NH\end{array}\right.$ (di-oxy-isoquinoline). By dry HCl at 150° it is converted into chloro-oxy-isoquinoline (Gabriel, *B.* 19, 2359).

Ethyl derivative  $C_6H_4\left\langle\begin{array}{l}CH{=\!=}CCl\\ \quad\quad\quad |\\ C(OEt):N\end{array}\right.$. [37°]. Formed by heating di-chloro-isoquinoline with alcoholic sodium ethylate at 100°. Long needles. V. sol. ordinary solvents (Gabriel, *B.* 19, 2358).

(*Py.* 4:2)-Chloro-oxy-isoquinoline C_9H_6ClNO *i.e.*  $C_6H_4\left\langle\begin{array}{l}CH:C(OH)\\ \quad\quad |\\ CCl:N\end{array}\right.$ or  $C_6H_4\left\langle\begin{array}{l}CH_2.CO\\ \quad\quad |\\ CCl:N\end{array}\right.$ [197°]. Formed as a by-product in the preparation of di-chloro-isoquinoline by the action of $POCl_3$ at 150°–170° upon the imide of phenyl-acetic-*o*-carboxylic acid  $C_6H_4\left\langle\begin{array}{l}CH_2.CO\\ \quad\quad |\\ CO.NH\end{array}\right.$ (di-oxy-isoquinoline). Long thick needles, or colourless plates. M. sol. hot alcohol, sl. sol. ether, cold acetic acid, hot benzene, and chloroform.

Methyl derivative $C_9H_5(CH_3)NO$: [67°]. Small white crystals; v. sol. alcohol, ether, &c., insol. alkalis. Formed by heating chloro-oxy-isoquinoline with MeI and methyl-alcoholic KOH (Gabriel, *B.* 19, 2355).

Di-chloro-oxy-isoquinoline (?) $C_9H_5Cl_2NO$ probably  $C_6H_4\left\langle\begin{array}{l}CO.CHCl\\ \quad\quad |\\ CCl:N\end{array}\right.$. Formed by heating hippuric acid with PCl_5. By further action of PCl_5 it is converted into a body $C_9H_4NCl_3$, [134°] (Rügheimer, *B.* 19, 1169; *cf.* Schwanert, *A.* 112, 59).

DI-*p*-CHLORO-DI-OXY QUINONE $C_6Cl_2(OH)_2O_2$ [1:4:2:5:3:6]. *Chloranilic acid* (Hantzsch, *B.* 20, 1303, 2279).

Formation.—1. By dissolving tetra-chloro-quinone (chloranil) in dilute aqueous KOH (Erdmann, *J. pr.* 22, 281; *cf.* Stenhouse, *A. Suppl.* 8, 14).—2. By the action of potash on tri-chloro-quinone (Graebe, *A.* 146, 24).

Properties.—Glittering red plates (containing aq). May be partially sublimed. Its aqueous solution is violet, but decolourised by HCl or H_2SO_4, by which it is ppd.

Reactions.—1. *Reduced* by tin and HCl to di-chloro-tetra-oxy-benzene.—2. PCl_5 forms tetra-chloro-quinone.—3. By treatment with *bromine* it is converted into di-chloro-tetra-bromo-acetone $CBr_2Cl.CO.CBr_2Cl$ [79°] (Levy a. Jedlička, *B.* 20, 2318; *cf.* Stenhouse, *A. Suppl.* 8, 17).—4. HCl and $KClO_3$ *form* tetra-chloro-acetone $CHCl_2.CO.CHCl_2$, which crystallises with 4aq [49°] (Levy a. Jedlička, *B.* 21, 318).—5. *Ammonia* forms $C_6Cl_2O_2(NH_2)(OH)$ 3aq crystallising in black needles and forming the salts $C_6Cl_2O_2(NH_2)(ONH_4)$ 4aq and $C_6Cl_2O_2(NH_2)(OAg)$. 6. A small quantity of SO_2 forms tetra-chloro-tetra-oxy-quinhydrone $C_{12}H_6Cl_4O_8$, crystallising in black needles.

Salts.—$K_2C_6Cl_2O_4$ aq: purple prisms, forming a purple solution in water or alcohol.—Na_2A''4aq: dark crimson needles (Hesse, *A.* 114, 304).—BaA''3aq: red-brown scales.—Ag_2A'': red pp.

Di-ethyl ether $Et_2C_6Cl_2O_4$. Red prisms (from alcohol).

CHLORO-DI-OXY-QUINONE SULPHONIC ACID $C_6H_3ClSO_7$ *i.e.* $C_6Cl(OH)_2O_2(SO_3H)$. **Potassium salt** $C_6Cl(OK)_2O_2(SO_3K)$ 2aq. From tri-chloro-hydroquinone sulphonic acid and KOH (Græbe, *A.* 146, 55). Red needles; v. sol. water, insol. alcohol. With HCl it gives yellow laminæ of $C_6Cl(OH)_2O_2(SO_3K)$, decolourised by tin and HCl.

DI-*p*-CHLORO-DI-*p*-OXY-TEREPHTHALIC ACID $C_6Cl_2(OH)_2(CO_2H)_2$ [1:4:2:5:3:6]. From the colourless ether (*v. infra*) and conc. aqueous NaOH at 100°. Greenish-yellow needles (containing 2aq). Stable in the air, but effloresces over H_2SO_4 into the white anhydrous pseudo-form (di-chloro-quinone di-hydro-di-carboxylic acid) which is reconverted into the unstable form by heating with aqueous NaOH.

Ethyl ether. Di-chloro-hydroquinone-di-carboxylic ether. [123°]. Formed by reduction of di-chloro-quinone-di-carboxylic ether $C_6Cl_2O_2(CO_2Et)_2$ with zinc-dust and acetic acid. Long thin colourless needles. V. sol. ether. By melting and quick cooling it is converted into yellowish-green dichroic tables, which are probably the *pseudo-form* $C_6H_2Cl_2O_2(CO_2Et)_2$ (di-chloro-quinone-di-hydro-di-carboxylic ether); this is unstable, and by a gentle warming is converted back into the colourless needles of the stable form (Hantzsch a. Zeckendorf, *B.* 20, 1812).

CHLORO-OXY-THYMOQUINONE $C_{10}H_{10}(OH)ClO_2$ *i.e.* $C_6Cl(CH_3)(C_3H_7)O_2(OH)$. [122°]. From di-nitro-thymol by treatment with PCl_5, the chloro-di-nitro-thymol so formed being reduced by tin and HCl and the resulting amido- compound oxidised by CrO_3 (Ladenburg a. Engelbrecht, *B.* 10, 1218). Lemon-yellow prisms (from alcohol). Readily sublimes. Its alkaline solutions are violet. Boiling with KOH converts it into di-oxy-thymoquinone.

CHLORO-OXY-TOLUCARBOSTYRIL Chloro-di-oxy-methyl-quinoline.

CHLORO-OXY-TOLUQUINOLINE *v.* CHLORO-OXY-METHYL-QUINOLINE.

DI-CHLORO-DI-OXY-TOLUQUINONE (?) $C_7H_4Cl_2O_4$ *i.e.* $C_6Cl_2Me(OH)O_2$. [157°]. From tri-chloro-orcin and alkaline K_3FeCy_6 (Stenhouse a. Groves, *B.* 13, 1306). Deep yellow scales (from water). Sl. sol. water, v. sol. alcohol. Reduced by SO_2 to colourless $C_7H_6Cl_2O_4$, which on oxidation gives purplish-brown crystals of a quinhydrone. A di-chloro-di-oxy-toluquinone has been described by Bräuninger (*A.* 185, 339) as obtained from beech-wood creosote by treatment with $KClO_3$ and HCl; the resulting tetra-chloro-toluquinone being reduced by SO_2 to the tetra-chloro-hydrotoluquinone, whence dilute KOH forms di-chloro-di-oxy-toluquinone, a brick-red crystalline powder.

DI-CHLORO-DI-OXY-DI-*o*-TOLYL-PYRAZINE

$$\begin{array}{l} C_7H_7.N-CCl.CO \\ \quad\; | \quad\;\; | \quad\;\; | \\ \quad\;\; CO.CCl.N.C_7H_7 \end{array}$$

[201°]. From di-oxy-di-tolyl-pyrazine dihydride and PCl_5 (Abenius a. Widmann, *B.* 21, 1662).

CHLORO-OXY-VALERIC ACID $C_3H_5Cl(OH).CH_2.CO_2H$. Obtained by oxidising chloro-allyl-propyl alcohol by chromic mixture (Lopatkin, *J. pr.* [2] 30, 396). Crystalline.

Salts.—$BaA'_2$3aq.—NaA′aq.

γ-Chloro-γ-oxy-valeric acid

Lactone. $C_5H_7O_2Cl$ *i.e.* $\underbrace{CH_3.CCl.CH_2.CH_2.CO.O}$ (80°–82°) at 10 mm. Got by passing HCl into (α)-angelico-lactone. Decomposed by water into HCl and levulic acid. On distillation it splits up into HCl and (β)-angelico-lactone. Bromine converts the lactone into brominated bodies, whence water forms a great deal of di-bromo-levulic acid and some bromo-levulic acid (Wolff, *A.* 229, 249).

Chloro-oxy-valeric acid $C_5H_9ClO_3$ *i.e.* $CH_3.CHCl.CMe(OH).CO_2H$. [75°]. Formed, together with its isomeride, by the union of tiglic acid with HOCl (Melikoff, *A.* 234, 225; *Bl.* [2] 47, 166). Needles, sol. water, alcohol, and ether. Alcoholic KOH converts it into butylene oxide carboxylic (di-methyl-glycidic) acid

$$CH_3.\overset{\;\;O\;\;}{\overbrace{CH.CMe}}.CO_2H$$

[62°], whence HCl reproduces the original acid [75°].

Salts.—ZnA'_2.—CaA'_2: prisms.

Chloro-oxy-valeric acid $CH_3.CH(OH).CMeCl.CO_2H$. [112°]. Formed, together with the preceding, by the union of HOCl with tiglic acid (M.). Prisms; v. sol. water, alcohol, and ether. Alcoholic KOH converts it into the same butylene oxide carboxylic acid as the preceding.

Salts.—These are gummy masses.—ZnA'_2.—CaA'_2.—BaA'_2.

Tri-chloro-oxy-valeric acid $CH_3.CHCl.CCl_2.CH(OH).CO_2H$. [140°]. Prepared by boiling with HCl the compound of tri-chloro-butyric aldehyde with HCN (Pinner a. Klein, *B.* 11, 1492; *A.* 179, 99). Trimetric tables, v. sol. alcohol, ether, and hot water.

Salts.—NaA′aq: crystals.—PbA'_2 amorphous pp.

Ethyl ether EtA′. [40°]. (255°). Long prisms. Alcoholic NH_3 converts it into $C_5H_7ClN_2O$ (? amide of chloro-imido-angelic acid) [118°] whence boiling alcohol produces $C_5H_8ClNO_2$.

Acetyl derivative $C_5H_6AcCl_2O_2$aq. [84°]. Slender needles.

Tri-chloro-ethylidene ether $CCl_3CH\Big\langle\begin{smallmatrix}O\\O.CO\end{smallmatrix}\Big\rangle CH.CCl_2.CHCl.CH_3$. [87°]. (297°). From the acid and chloral at 175° (Wallach, *A.* 193, 87). Thick crystals (from chloroform); explodes when struck.

Amide $CH_3.CHCl.CCl_2.CH(OH).CO.NH_2$ [119°]. Sl. sol. water and C_6H_6, v. sol. alcohol and ether. Prepared by the action of strong H_2SO_4 on the nitrile (Pinner a. Klein, *B.* 11, 1490).

Nitrile $CH_3.CHCl.CCl_2.CH(OH).CN$. *Butyl-chloral cyanhydrin.* [102°]. (c. 230°). From tri-chloro-butyric orthaldehyde, alcohol, and conc. HCyAq. Leaflets (from dilute HClAq); m. sol. cold water, v. sol. alcohol. Converted by alcoholic NH_3 into the amide of (β)-chloro-crotonic acid. Urea gives chloro-crotonyl-urea $C_3H_4Cl.CONH.CO.NH_2$ and butyro-chloral biuret.

Acetyl derivative of the nitrile $CH_3.CHCl.CCl_2.CH(OAc).CN$. (240°–252°). From the nitrile and AcCl. Yellowish oil.

TETRA-CHLORO-ω-DI-OXY-XYLENE. ***Anhydride*** $C_8H_4Cl_4O$ *i.e.* $C_6Cl_4\Big\langle\begin{smallmatrix}CH_2\\CH_2\end{smallmatrix}\Big\rangle O$. [218°]. From tetra-chloro-phthalic acid (7·7 g.), conc. HI (3·5 c.c.) and red phosphorus (2 g.) at 230° (Graebe, *A.* 238, 331). Needles (from toluene). Sl. sol. hot alcohol, m. sol. hot benzene or HOAc. Insol. boiling alkalis.

CHLORO-PENTANE *v.* AMYL CHLORIDE.

Di-chloro-pentane $C_5H_{10}Cl_2$. *Amylene chloride.* (145°). S.G. ^{0} 1·22; ^{12} 1·058. From crude amylene and PCl_5 (Guthrie, *C. J.* 14, 128; *A.* 121, 115) or Cl, the temperature being first at −15°, afterwards boiling (Bauer, *Z.* [2] 4, 380, 667; *cf.* Kondakoff, *C. C.* 1887, 979).

Di-chloro-pentane $(CH_3)_2CH.CH_2.CHCl_2$. *Isoamylidene chloride.* (130°). S.G. ^{24} 1·05. From isovaleric aldehyde and PCl_5 (Ebersbach, *A.* 106, 265). KOH gives $(CH_3)_2CH.CH:CHCl$ (86°) and $(CH_3)_2CH.C{:}CH$ (Bruylants, *B.* 8, 413).

αα-Di-chloro-pentane $CH_3.CH_2.CH_2.CCl_2.CH_3$. From methyl propyl ketone and PCl_5 (Bruylants, *B.* 8, 411). Liquid; decomposed by distillation. Dry KOH forms $CH_3.CH_2.CH_2.C{:}CH$. Alcoholic KOH forms $CH_3.CH_2.CH_2.CCl:CH_2$ (96°) and $CH_3.C{:}C.C_2H_5$ (Favorsky, *Bl.* [2] 45, 247).

Di-chloro-pentane $C_5H_{10}Cl_2$. (155°–160°). S.G. ^{9} 1·19. Formed by chlorination of ordinary amyl chloride (Buff, *A.* 148, 350).

Di-chloro-pentane $C_5H_{10}Cl_2$. (151°). From valerylene and HCl at 100° (Reboul, *Z.* 1867, 173). Heavy oil.

Tri-chloro-pentane $C_5H_9Cl_3$. (185°–190°). S.G. ^{12} 1·33. By chlorination of ordinary amyl chloride (Buff, *A.* 148, 350). A crystalline tri-chloro-pentane is formed (160°–190°) by chlorinating crude amylene (Bauer, *J. pr.* 100, 42).

Tetra-chloro-pentane $C_5H_8Cl_4$. (240°). S.G. ^{9} 1·429. From amylene and Cl (Bauer, *J. pr.* 100, 43).

Penta- and Hexa-chloro-pentanes have been obtained by Spring a. Lecrenier (*Bl.* [2] 48, 623) by chlorinating isoamyl mercaptan.

CHLORO-ISO-PENTANE SULPHONIC ACID $C_5H_{10}Cl.SO_3H$. From isopentane sulphonic acid and Cl in sunshine or, in presence of iodine, at 130° (Spring a. Winssinger, *B.* 17, 537; *Bl.* [2] 41, 301).—BaA′$_2$.

CHLORO-PENTENOIC ACID *v.* CHLORO-ANGELIC ACID and CHLORO-TIGLIC ACID.

CHLORO-PENTENYL ALCOHOL $CH_2.CH{:}CCl.CHMe.OH$. *Methyl-chloro-allyl carbinol.* (159°) at 725 mm. S.G. $\frac{14\cdot1}{14\cdot1}$ 1·0882. V.D. 4·09 (Theory 4·17). From tri-chloro-amyl-alcohol $C_3H_4Cl_3.CHMe.OH$, finely divided iron, and acetic acid (Garzarolli-Thurnlackh, *A.* 223, 154), or zinc-dust and dilute HCl. Colourless mobile liquid with pungent smell, faintly soluble in water, soluble in ether, CS_2, and chloroform. Combines with bromine. Acetic acid is among the products of oxidation by chromic mixture.

Acetyl derivative C_5H_8AcClO. (173°) at 735 mm. V.D. 5·73 (for 5·66). Does not combine with bromine.

PER-CHLORO-PENTINENE C_5Cl_8. *Per-chloro-mecylene.* [89°]. From comenic acid and PCl_5 at 280° (Ost, *J. pr.* [2] 27, 293). Prisms (from alcohol); smells like camphor. Begins to distil with decomposition at 270°.

CHLORO-PHENANTHRENE *v.* PHENANTHRENE.

CHLORO-PHENETOL *v.* *Ethyl ether* of CHLORO-PHENOL.

***o*-CHLORO-PHENOL** $C_6H_4Cl(OH)$ [2:1]. [7°]. (176° i.V.).

Formation.—1. From *o*-amido-phenol by displacing NH_2 by Cl by the diazo- reaction (Schmitt a. Cook, *B.* 1, 67; Faust a. Müller, *B.* 5, 777). Solution of $NaNO_2$ is run into a hot solution of *o*-amido-phenol and Cu_2Cl_2 in dilute HCl (Sandmeyer, *B.* 17, 2651).—2. Together with the *p*-isomeride by passing chlorine into phenol (F. a. M.; Krämers, *A.* 173, 331).—3. From *o*-chloro-aniline by displacing NH_2 by OH through the diazo- reaction (Beilstein a. Kurbatoff, *A.* 176, 39).—4. Formed by neutralising with acid a mixture of sodium hypochlorite and phenol (Chandelon, *B.* 16, 1749).

Properties.—Colourless liquid; sl. sol. water, v. sol. alcohol and ether. Potash-fusion converts it into pyrocatechin (Petersen, *B.* 6, 368). HNO_3 gives two chloro-nitro-phenols [111°] and [70°]. PCl_5 gives *o*-di-chloro-benzene (179°).

Methyl ether $C_6H_4Cl(OMe)$. *o-Chloro-anisol.* (203°). Prepared from *o*-anisidine $C_6H_4(NH_2)(OMe)$ by Sandmeyer's reaction (Wallach a. Hensler, *A.* 243, 237; *cf.* Fischli, *B.* 11, 1463).

Ethyl ether $C_6H_4Cl(OEt)$. *o-Chloro-phenetol.* (208°).

Benzoyl derivative $C_6H_4Cl.OBz$. (314°).

Phthalyl derivative $C_8H_4O_2O_2(OC_6H_4Cl)_2$. [98°] (Mosso, *C. C.* 1887, 1396).

***m*-Chloro-phenol** $C_6H_4Cl(OH)$[3:1]. [28·5°]. (214° i. V.). From *m*-chloro-aniline by displacing NH_2 by OH through the diazo- reaction (Beilstein a. Kurbatoff, *A.* 176, 45; Uhlemann, *B.* 11, 1161; Varnholt, *J. pr.* [2] 36, 26). White needles.

Benzoyl derivative $C_6H_4Cl(OBz)$. [86°].

Phthalyl derivative [108°] (Mosso).

***p*-Chloro-phenol** $C_6H_4Cl(OH)$[4:1]. [37°]. (217°).

Formation.—1. From phenol and SO_2Cl_2 (Dubois, *Z.* [2] 2, 705; 3, 205).—2. Together with the *o*-isomeride by passing chlorine into cold phenol (D.; Petersen a. Bähr-Praderi, *A.* 157, 123).—3. From *p*-amido-phenol by displacing NH_2 by Cl through the diazo- reaction (Schmitt, *B.* 1, 67).—4. From *p*-chloro-aniline by displacing NH_2 by OH through the diazo-reaction (Beilstein a. Kurbatoff, *A.* 176, 30; *B.* 7, 1395).

Properties.—Crystalline; v. sl. sol. water, v. e. sol. alcohol and ether. Insol. aqueous Na_2CO_3. Potash-fusion converts it into hydroquinone and resorcin (Petersen, *B.* 6, 1399; 7, 61; *cf.* Faust, *B.* 6, 1022). PCl_5 gives *p*-di-chloro-benzene [53°]. HNO_3 forms chloro-nitro-phenol [87°].

Salt.—$C_6H_4Cl(ONa)$ (Varnholt, *J. pr.* [2] 36, 19).

Methyl ether $C_6H_4Cl(OMe)$. (c. 200°); S.G. $\frac{0}{0}$ 1·182 (Henry, *Z.* [2] 6, 247).

Ethyl ether $C_6H_4Cl(OEt)$. [21°]. (211°).

Benzoyl derivative $C_6H_4Cl(OBz)$. [93°].

Phthalyl derivative $C_6H_4(CO_2C_6H_4Cl)_2$. [11°] (Mosso).

(4:2:1)-Di-chloro-phenol $C_6H_3Cl_2(OH)$[4:2:1] [42°]. (210°).

Formation.—1. By chlorinating phenol (Laurent, *A. Ch.* [2] 63, 27; [3] 3, 210; F. Fischer, *Z.* [2] 4, 386; *A. Suppl.* 7, 180).—2. By adding HCl to a mixture of phenol (1 mol.) and sodium hypochlorite (2 mols.), the (6:2:1)-isomeride is formed simultaneously (Chandelon. *B.* 16, 1751).

Properties.—White needles. Sol. alcohol and ether, nearly insol. water. Expels CO_2 from boiling aqueous Na_2CO_3, but in the cold it is ppd. from its salts by CO_2. PCl_5 gives tri-chloro-benzene [16°].

Salts.—$NH_4O.C_6H_4Cl$: needles (from hot NH_3Aq).—KA′ ½aq: decomposed by water at 70°, giving off *p*-chloro-phenol.—HOPbA′.—AgA′.

Ethyl ether $C_6H_4Cl(OEt)$. (237°).

Acetyl derivative $C_6H_4Cl(OAc)$. (245°).

Benzoyl derivative $C_6H_3Cl_2OBz$. [97°].

Phthalyl derivative $C_6H_4(CO_2C_6H_3Cl_2)_2$. [108°] (Mosso, *Ann. Chim. Farm.* 87, 184).

(6:2:1)-Di-chloro-phenol $C_6H_3Cl_2(OH)$[6:2:1] [63°]. (218°).

Formation.—1. Together with the (4:2:1) isomeride by adding HCl to a mixture of phenol (1 mol.) and sodium hypochlorite (2 mols.) (Chandelon, *B.* 16, 1752).—2. From di-chloro-*p*-amido-phenol by displacing NH_2 by Cl through the diazo- reaction (Seifart, *A. Suppl.* 7, 203; *Z.* [2] 5, 450).

Properties.—Needles. Sol. alcohol and ether, nearly insol. water.

Tri-chloro-phenol $C_6H_2Cl_3(OH)$[6:4:2:1]. [68°]. (244°). S. ·051 at 14°; ·243 at 96°.

Formation.—1. By chlorination of phenol (Laurent, *A. Ch.* [2] 63, 27; [3] 3, 497), of saligenin (the product being distilled with conc. H_2SO_4, Piria, *A.* 56, 47), of aniline (Hofmann, *A.* 53, 8), of indigo (Erdmann, *J. pr.* 19, 332; 22, 276; 25, 472), of phenol sulphonic acid (Vogel, *Z.* 1865, 529), or of phenyl benzyl oxide $C_6H_5O.CH_2Ph$ (Sintenis, *A.* 161, 338).—2. By the action of NaOCl upon (2, 6, 1)-di-chloro-phenol [65°], and upon (2, 4, 1)-di-chloro-phenol [43°] (Chandelon, *Bl.* [2] 38, 123).

Properties.—Needles or prisms. Acid to litmus.

Reactions.—1. HNO_3 forms di-chloro-quinone [120°]; alcohol and N_2O_3 produce the same body.—2. PCl_5 or Fe_2Cl_6 from tetra-chloro-benzene.—3. HCl and $KClO_3$ give tetra-chloro-quinone. CrO_3 and HOAc produce the same body (Levy a. Schultz, *A.* 210, 160).—4. K_2SO_4 at 170° gives chloro-phenol disulphonic acid and di-chloro-phenol sulphonic acid (Armstrong a. Harrow, *C. J.* 29, 474).—5. Br gives $C_6H_2Cl_2OBr$ [99°] (Benedikt, *M.* 4, 235).

Salts.—$NH_4C_6H_3Cl_2O$: needles; v. sl. sol. cold water.—KA′ ½aq.—MgA'_2 2aq.—BaA'_2 4aq: radiate groups of laminæ.—PbA'_2.—$(PbA'_2)_4PbO$. AgA′: yellow amorphous pp.

Ethyl ether $C_6H_3Cl_2(OEt)$: [44°]. (240°). (Faust, *A.* 149, 152; Lampert, *J. pr.* [2] 33, 381).

Acetyl derivative $C_6H_3Cl_2(OAc)$. (262°).

Propionyl derivative $C_6H_3Cl_2.O(CO.C_2H_5)$ (268° uncor.), colourless heavy liquid.

Butyryl derivative $C_6H_3Cl_2.O(CO.C_3H_7)$: (274° uncor.).

Valeryl derivative $C_6H_3Cl_2.O(CO.C_4H_9)$: (283° uncor.).

Benzoyl derivative $C_6H_3Cl_2.OBz$: [70°]; colourless needles; sol. alcohol and ether, insol. water.

Phthalyl derivative $C_6H_3Cl_2.O<{CO \atop CO}>C_6H_4$: [194°]; v. sol. chloroform, sl. sol. alcohol and ether, insol. water (Daccomo, *B.* 18, 1168).

Tri-chloro-phenol $C_6H_2Cl_3(OH)$. [54°]. (253° uncor.). From tri-chloro-*p*-amido-phenol (Lampert, *J. pr.* [2] 33, 378). Also from phenol and NaOCl (Chandelon, *Bl.* [2] 38, 119). Silky needles (from dilute alcohol). Volatile with steam. HNO_3 gives no quinone, but a nitro-derivative [146°]. PCl_5 gives C_6HCl_5.

Ethyl ether $C_6H_2Cl_3(OEt)$; (246° uncor.).

Acetyl derivative $C_6H_2Cl_3(OAc)$; (259° uncor.).

Tetra-chloro-phenol $C_6H_2Cl_3(OCl)$[6:4:2:1] or $C_6H_2Cl_2(Cl_2)O$. '*Tri-chloro-phenol chloride.*' [119°]. Formed by passing Cl into tri-chloro-phenol suspended in fuming aqueous HCl (Benedikt, *M.* 4, 233). Trimetric pyramids; $a:b:c = 1:\cdot614:\cdot51$. May be distilled. Conc. KOHAq turns the crystals blue, and on boiling forms tri-chloro-phenol. Hot conc. H_2SO_4 gives tri-chloro-phenol and tetra-chloro-quinone.

Penta-chloro-phenol $C_6Cl_5(OH)$ [188°].

Formation.—1. By the action of chlorine on an alcoholic solution of tri-chloro-phenol, chloro-isatin, or di-chloro-isatin (Erdmann, *J. pr.* 22, 272; Laurent, *A. Ch.* [3] 3, 497).—2. From phenol and chloride of iodine (Schützenberger, *Bl.* [2] 4, 102).—3. By passing chlorine into a mixture of phenol or tri-chloro-phenol and $SbCl_5$ at 200° (Merz a. Weith, *B.* 5, 458; Benedikt a. Schmidt, *M.* 4, 606).—4. Obtained by heating hexa-chloro-benzene with a glycerin solution of NaOH at 250°–280°. *Properties.*—Sublimes in long white needles. HNO_3 forms tetra-chloro-quinone. PCl_5 gives C_6Cl_6.

Salts.—C_6Cl_5ONa.—KA′.—AgA′.

Methyl ether $C_6Cl_5(OMe)$: [108°]; long white needles; v. sol. alcohol; sublimable.

Acetyl derivative $C_6Cl_5(OAc)$: [148°]; fine white needles; v. sol. alcohol; sublimable (Weber a. Wolff, *B.* 18, 335).

Dichloride $C_6Cl_5(OH).Cl_2$ [78½°–80°]. Formed in the chlorination of *m*-chloro-acetanilide in acetic acid (Beilstein, *B.* 11, 2182). Large colourless pillars. Difficultly soluble in 50 p.c. acetic acid, easily in C_6H_6, $CHCl_3$, CS_2, alcohol, &c. Alkalis decompose it entirely. On heating with alcohol per-chloro-phenol is formed.

Hexa-chloro-phenol C_6Cl_6O. [46°]. Formed by passing Cl into a solution of penta-chloro-phenol in dilute HCl (Benedikt a. Schmidt, *M.* 4, 607). Golden-yellow crystals; gives off chlorine on heating. Tin and HCl re-convert it into penta-chloro-phenol.

Dichloride C_6Cl_8O. [102°]. Formed by chlorinating penta-chloro-phenol in acetic acid solution (B. a. S.). Prisms (from ligroïn).

Hexa-chloro-phenol C_6Cl_6O. [106°]. From penta-chloro-aniline by chlorination in acetic acid solution (Langer, *A.* 215, 122). Yellowish prisms (from ligroïn).

Per-chloro-diphenol v. OCTO-CHLORO-DI-OXY-DIPHENYL.

o-CHLORO-PHENOL (γ)-SULPHONIC ACID $C_6H_5ClSO_4$ *i.e.* $C_6H_3Cl(OH)SO_3H$. From *o*-chloro-phenol and fuming H_2SO_4 (Krämers, *A.* 173, 331). Small colourless plates or cubes (containing aq). V. e. sol. water and alcohol. It begins to decompose at 80°. Fe_2Cl_6 colours its solutions violet. HNO_3 forms chloro-di-nitro-phenol [111°].

Salts.—KA′ ½aq: S. (of KA′) 14 at 9°.—$K_2C_6H_3ClSO_4$ 3½aq: deliquescent laminæ.—NaA′ aq.—$Na_2C_6H_3ClSO_4$ 3aq.—CaA'_2 aq.—$CaC_6H_3ClSO_4$ 3½aq: efflorescent crystalline aggregates; S. 38 at 12°.—BaA'_2 1½aq: granular aggregates of crystals.—PbA'_2 4aq.—$PbC_6H_3ClSO_4$ aq.—CuA'_2 4aq: bluish-green trimetric prisms.

o-Chloro-phenol (δ)-sulphonic acid $C_6H_3Cl(OH)SO_3H$. Formed, together with the preceding, when the sulphonation is effected in the cold by fuming H_2SO_4 (1 pt.) mixed with conc. H_2SO_4 (1½ pts.) (K.).—KA′: small plates. $CaC_6H_3ClSO_4$ 2aq: small needles; S. 2·25 at 11°.

o-Chloro-phenol (β)-sulphonic acid $C_6H_3Cl(OH)SO_3H$. Obtained, in small quantity, in sulphonating impure *p*-chloro-phenol (Petersen a. Baehr-Praderi, *A.* 157, 129). Potash-fusion gives pyrogallol. Fe_2Cl_6 colours its neutral solutions violet. HNO_3 gives chloro-di-nitro-phenol [81°].—KA′: stellate groups of short prisms; less soluble than potassium *p*-chloro-phenol sulphonate.

p-Chloro-phenol (α)-sulphonic acid $C_6H_3Cl(OH)(SO_3H)$. [76°]. From *p*-chloro-phenol and fuming H_2SO_4 at 100° (Petersen a. Baehr-Praderi, *A.* 157, 121). Glittering plates (containing aq). Begins to decompose at 100°. Gives a bluish-violet colour with Fe_2Cl_6. Potash-fusion gives pyrogallol and a trace of hydroquinone. HNO_3 forms chloro-nitro-phenol sulphonic acid (Armstrong, *B.* 7, 404) and chloro-di-nitro-phenol [81°].

Salts.—KA′ 2aq: flat monoclinic prisms; S. 10·8 at 20°; 44·3 at 100°.—KA′ aq.—KA′ (from alcohol): needles.—NaA′: groups of needles.—LiA′ aq.—NH_4A': [280°].—BaA'_2.—$BaC_6H_3ClSO_4$ 2aq.—CaA'_2 2aq: easily soluble needles.—MgA'_2 6aq: small flat plates or needles.—CuA'_2 6aq: greenish-white needles, v. e. sol. water.

Ethyl derivative $C_6H_3Cl(OEt)SO_3H$.

Salt.—KA′: stellate groups of needles.

Chloro-phenol disulphonic acid $C_6H_2Cl(OH)(SO_3H)_2$ [4:1:6:2]. Formed, together with di-chloro-phenol sulphonic acid, by heating tri-chloro-phenol with K_2SO_4 at 170° (Armstrong a. Harrow, *C. J.* 29, 474). The same acid appears to be formed by sulphonating *p*-chloro-phenol at 100° (Petersen a. Baehr-Praderi, *A.* 157, 153). Conc. HNO_3 forms chloro-di-nitro-phenol [81°].

Di-chloro-phenol sulphonic acid $C_6H_2Cl_2(OH)(SO_3H)$ [4:2:1:6]. From (4,2,1)-di-chloro-phenol and $ClSO_3H$ [43°] (Armstrong, *C. J.* 25, 93). Formed also by chlorinating phenol *o*-sulphonic acid; and by heating tri-chloro-phenol with K_2SO_4 at 170° (Armstrong a. Harrow). HNO_3 (S.G. 1·36) forms di-chloro-nitro-phenol [121°].

Di-chloro-phenol sulphonic acid $C_6H_2Cl_2(OH)(SO_3H)$ [2:6:1:4]. Formed by chlorinating phenol *p*-sulphonic acid (Kolbe a. Gauhe, *A.* 147, 76) and by sulphonating (2,6,1)-di-chloro-phenol. Deliquescent trimetric tables or prisms. HNO_2 forms di-chloro-nitro-phenol and chloro-di-nitro-phenol [111°] (Faust, *Z.* 1871, 338; Armstrong, *C. J.* 24, 1112).—BaA'_2 2aq (dried at 100°).

Tri-chloro-phenol sulphonic acid $C_6HCl_3(OH)(SO_3H)$. From tri-chloro-phenol and $ClSO_3H$ (Armstrong, *C. J.* 25, 97; *cf.* Kekulé, *K.* 3, 233). Its aqueous solutions decompose with deposition of tri-chloro-phenol.

TRI-CHLORO-PHENOMALIC ACID $C_6H_3Cl_3O_3$ *i.e.* $CCl_3.CO.CH{:}CH.CO_2H$ or

$$\begin{matrix}\mathrm{CH.C(OH).CCl_3}\\ \| \quad\quad >\mathrm{O}\\ \mathrm{CH.CO}\end{matrix}$$

(Anschütz, *A.* 239, 176). *Tri-chloro-acetyl-acrylic acid.* [132°]. From benzene (80g.), H_2SO_4 (1,200 g.) and water (600 g.), to which $KClO_3$ (120 g.) is slowly (in 5 days) added with gentle shaking. The benzene is then separated and evaporated, the residue is extracted with water and the acid (6 g.) extracted from the water by ether (Carius, *A.* 140, 317; 142, 131; Kekulé a. O. Strecker, *A.* 223, 179). Quinone may be substituted for benzene.

Properties.—Glittering plates (from water). May be sublimed. Is volatile with steam.

Reactions.—1. Warmed with baryta it gives chloroform and baric maleate.—2. Combines with bromine in chloroform with formation of $CCl_3.CO.CHBr.CHBr.CO_2H$ [97·5°]. This is sl. sol. water, v. sol. alcohol, ether, and chloroform. Boiled with lime water, it gives chloroform and inactive calcic tartrate.

Theory of Formation.—Kekulé supposes that it is produced from chloro-quinone, and if this is written

$$\mathrm{CO}<\begin{matrix}\mathrm{CH{:}CH}\\ \mathrm{CH{:}CCl}\end{matrix}>\mathrm{CO}$$

the conversion of it into

$$\mathrm{CO}<\begin{matrix}\mathrm{CH{:}CH}\\ \mathrm{OH\ CCl_3}\end{matrix}>\mathrm{CO}$$

does not appear very difficult to understand.

CHLORO-PHENOXY-ACETIC ACID $C_8H_7ClO_3$ *i.e.* $C_6H_4Cl.O.CH_2.CO_2H$. [152°]. From phenoxy-acetic acid by successive treatment with PCl_5 and water (Michael, *J. pr.* [2] 35, 96). Trimetric prisms (from water).

o-**CHLORO-DIPHENYL** $C_{12}H_9Cl$ *i.e.* $C_6H_5.C_6H_4Cl$ [2:1]. [34°]. (267°). Formed, together with the *p*-isomeride, by passing chlorine into diphenyl mixed with $SbCl_5$ (Krämers, *A.* 189, 142). Monoclinic crystals; v. sol. ligroïn. CrO_3 gives *o*-chloro-benzoic acid.

m-**Chloro-diphenyl** $C_6H_5.C_6H_4Cl$ [3:1]? [89°]. Formed by heating C_6H_5OK with calcium *m*-chloro-benzoic acid (Pfannkuch, *J. pr.* [2] 6, 106).

p-**Chloro-diphenyl** $C_6H_5.C_6H_4Cl$ [4:1]. [75°]. (282°). Formed by chlorinating diphenyl (*v. supra*) or by treating *p*-oxy-diphenyl with PCl_5 (G. Schultz, *B.* 7, 52). Thin plates (from ligroïn). Smells like oranges. May be oxidised to *p*-chloro-benzoic acid.

Di-*p*-chloro-diphenyl [4:1]$C_6H_4Cl.C_6H_4Cl$[1:4]. [148°]. (c. 317° cor.).

Formation.—1. Amongst the products of the action of PCl_5 on di-*p*-oxy-diphenyl (Schmidt a. Schultz, *B.* 12, 494; *A.* 207, 339).—2. From di-amido-diphenyl (benzidine) by displacement of NH_2 by Cl through the diazo- reaction (Griess, *Tr.* 1864, iii. 730); *e.g.* by heating tetrazo-diphenyl with a large excess of HCl; the yield being 16 p.c. of the theoretical (Gasiorowski a. Waÿss, *B.* 18, 1941).—3. By chlorinating diphenyl (Krämers, *A.* 189, 138, 145).—4. By passing chloro-benzene through a red-hot tube.

Properties.—Prisms or needles; insol. water, sl. sol. alcohol, v. sol. ether. CrO_3 gives *p*-chloro-benzoic acid.

Penta-chloro-diphenyl $C_{12}H_5Cl_5$. [179°]. Formed together with other products by the action of PCl_5 on di-*p*-oxy-diphenyl (Schmidt a. Schultz, *B.* 12, 495; *cf.* Doebner, *B.* 9, 130). Long needles. Sublimable.

Per-chloro-diphenyl $C_{12}Cl_{10}$. Prepared by exhaustive chlorination of diphenyl in presence of $SbCl_5$ or iodine (Ruoff, *B.* 9, 1491; Weber a. Söllscher, *B.* 16, 882; Merz a. Weith, *B.* 16, 2881). Formed also by exhaustive chlorination of ditolyl (Merz a. Weith, *B.* 12, 677), benzidine, carbazole (Zetter, *B.* 10, 1233), and phenanthraquinone (Merz a. Weith, *B.* 16, 2871). Long tables or prisms. Does not melt below 270°. V. sl. sol. alcohol or ether. Not attacked by $SbCl_5$ even at 350°. Alcoholic NaOH at 150° gives $C_{12}Cl_8(OH)_2$.

α-**CHLORO-PHENYL-ACETIC ACID** $C_8H_7ClO_2$ *i.e.* $C_6H_5.CHCl.CO_2H$. [78°].

Formation.—1. From mandelic acid $C_6H_5.CH(OH).CO_2H$ and HCl at 140° (Radziszewski, *B.* 2, 208).—2. From benzoic aldehyde by conversion into PhCH(OH)CN by KCN and HCl, the mandelo-nitrile being then treated with HCl (Spiegel, *B.* 14, 235; R. Meyer, *A.* 220, 41). 3. From $C_6H_5.CH{:}CH.NO_2$ and fuming HCl at 100° (Priebs, *A.* 225, 337).

Properties.—Trimetric tables; sl. sol. cold water and ligroïn, v. e. sol. alcohol and ether. Sodium amalgam converts it into phenyl-acetic acid. Boiling aqueous KOH forms mandelic acid. Phenyl-hydrazine forms benzylidene-phenyl-hydrazine $C_6H_5CH{:}N_2HPh$ (Reissert, *B.* 17, 1452). The salts are unstable.

Methyl ether MeA′ (248° cor.). Oil (Meyer a. Boner, *B.* 14, 2392).

p-**Chloro-phenyl acetic acid** $C_6H_4ClCH_2.CO_2H$. [104°]. Prepared by saponification of the nitrile (Neuhof, *A.* 147, 346; Jackson a. Field, *P. Am. A.* 14, 58). Also by treating phenyl-acetic acid with Cl in sunshine (Radziszewski, *B.* 2, 208). Long needles (from water). V. sol. benzene,

water, alcohol, and ether.—AgA′: curdy mass.—CaA′$_2$ aq.

Amide $C_6H_4Cl.CH_2.CONH_2$. [175°]. Tables (from alcohol). V. sol. alcohol and ether, sl. sol. hot water.

Nitrile $C_6H_4Cl.CH_2.CN$. [29°]. From *p*-chloro-benzyl bromide by heating with alcoholic KCy (Jackson a. Field, *Am.* 2, 88). Prisms; sol. alcohol and ether.

Di-*a*-chloro-phenyl-acetic acid $C_6H_5.CCl_2.CO_2H$. [68°]. Prepared by the action of PCl_5 on phenyl-glyoxylic ether and subsequent saponification (Claisen, *B.* 12, 630). Small tables. V. sol. water, alcohol, and ether.

Ethyl ether A′Et. (263°–266°).

Nitrile $C_6H_5.CCl_2.CN$. (224°). From benzoyl cyanide and PCl_5 (C.).

DI-*a*-CHLORO-PHENYL-ACETIC ALDEHYDE $C_6H_5.CCl_2.CHO$. (295°). From chloral, benzene, and Al_2Cl_6 at 70°. The product is treated with water and fractionally distilled *in vacuo*, when the compound $C_6H_5.CCl_2.CHCl(OH)$ passes over at 180°. By the action of KOH it is converted into the aldehyde by removal of HCl (Combes, *C. R.* 98, 678). Liquid. Reduces Fehling's solution and combines with $NaHSO_3$, although with difficulty. Benzene and Al_2Cl_6 convert the aldehyde into tri-phenyl-methane.

CHLORO - PHENYL - ACRYLIC ACID *v.* CHLORO-CINNAMIC ACID.

CHLORO-PHENYL-AMIDO-CHLORO-NAPHTHOQUINONE *v.* CHLORO-NAPHTHOQUINONE-CHLORO-ANILIDE.

CHLORO-PHENYL-AMIDO-HYDRONAPHTHOQUINONE $C_{16}H_{12}ClNO_2$ *i.e.* $C_{10}H_4Cl(OH)_2(NHPh)$. [171°]. From chloro-naphthoquinone anilide and conc. aqueous $SnCl_2$ (Knapp a. Schultz, *A.* 210, 190).

Acetyl derivative [169°].

CHLORO-DI-PHENYL-DI-AMIDO-HYDROQUINONE $C_{18}H_{15}ClN_2O_2$ *i.e.* $C_6HCl(OH)_2(NHPh)_2$. From chloro-di-phenyl-di-amido-quinone, conc. $SnCl_2Aq$, and alcohol (Knapp a. Schultz, *A.* 210, 181). Slender needles. Decomposes about 223°. Readily oxidised to the corresponding quinone.

Di-chloro-di-phenyl-di-amido-hydroquinone $C_{18}H_{14}Cl_2N_2O_2$ *i.e.* $C_6Cl_2(NHPh)_2(OH)_2$. Formed by boiling di-chloro-di-phenyl-di-amido-quinone $C_6Cl_2(NPhH)_2O_2$ with conc. aqueous $SnCl_2$ (Knapp a. Schultz, *A.* 210, 181). Slender needles, v. sol. water. Oxidation gives $C_6Cl_2(NPhH)_2O_2$. Boiling Ac_2O gives long needles of $C_{18}H_{20}N_2O_6$ [255°].

***p*-CHLORO-DI-PHENYL-DI-*p*-AMIDO-TRI-PHENYL-METHANE** $C_6H_4Cl.CH(C_6H_4.NHPh)_2$. Not isolated in a pure state. Formed by heating together diphenylamine and *p*-chloro-benzaldehyde in presence of $ZnCl_2$. On oxidation it gives a green dye-stuff (Kaeswurm, *B.* 19, 745).

TRI-CHLORO-TRI-PHENYL-TRI-AMIDO-DI PHENYL-TOLYL-CARBINOL *v.* TRI-CHLORO-TRI-PHENYL-ROSANILINE.

CHLORO-PHENYL-AMIDO-QUINONES *v.* ANILIDES of CHLORO-QUINONES.

***p*-CHLORO-DI-PHENYL-AMINE** $PhNHC_6H_4Cl$. [74°]. Formed by treating diazotised *p*-amido-di-phenyl-amine with cuprous chloride (Ikuta, *A.* 243, 286). Long prisms. V. sl. sol. water, v. sol. ether, alcohol, benzene, petroleum ether. Yields a nitrosamine $PhN(NO)C_6H_4Cl$ [88°], v. sol. alcohol and ether, which on standing with alcoholic HCl is converted into the isomeric *p*-nitroso-chloro-di-phenyl-amine $C_6H_4(NO)NHC_6H_4Cl$ [159°]; green plates (from benzene).

Di-chloro-di-phenyl-amine $NH(C_6H_4Cl)_2$. [80°]. From the benzoyl derivative and alcoholic KOH at 160° (Claus a. Schaare, *B.* 15, 1286). Needles.

Benzoyl derivative $NBz(C_6H_4Cl)_2$. [153°]. From benzoyl-di-phenyl-amine by chlorination (C. a. S.; *cf.* Claus, *B.* 14, 2368). Needles (from alcohol).

Tetra-chloro-di-phenyl-amine $NH(C_6H_3Cl_2)_2$. [134°]. Formed by passing Cl into a solution of di-phenyl-amine in HOAc (Gnehm, *B.* 8, 1040). Prisms or needles.

Per-chloro-tri-phenyl-amine $N(C_6Cl_5)_3$. From tri-phenyl-amine by exhaustive chlorination (Ruoff, *B.* 9, 1494). Needles (from benzene-alcohol).

DI-CHLORO-PHENYL-ANTHRANOL

$$C_{20}H_{12}Cl_2O \textit{ i.e. } C_6H_4\left\langle\begin{matrix} C(C_6H_4Cl) \\ | \\ C(OH) - \end{matrix}\right\rangle C_6H_3Cl. \ [170°].$$

From $CO\genfrac{<}{}{0pt}{}{C_6H_4}{C_6H_3Cl}{>}C(OH).C_6H_4Cl$ (phenol-phthalidein chloride), acetic acid, and zinc-dust (Baeyer, *A.* 202, 95). Needles (from alcohol). V. sl. sol. alcohol; m. sol. acetone and ether, with bluish-green fluorescence.

Dihydride

$$C_6H_4\left\langle\begin{matrix} CH(C_6H_4Cl) \\ CH(OH) - \end{matrix}\right\rangle C_6H_3Cl.$$

Hydrophenolphthalidin chloride. [56°]. From the preceding by heating in alcoholic solution with sodium amalgam (B.). Long needles (from CS_2).

PER-CHLORO-DI-PHENYL-BENZENE $C_{18}Cl_{14}$. Formed by exhaustive chlorination of di-phenyl-benzene by means of $SbCl_5$ (Merz a. Weith, *B.* 16, 2884). Colourless needles. V. sol. hot nitrobenzene, sl. sol. alcohol, ether, and acetic acid.

Per-chloro-tri-phenyl-benzene $C_{24}Cl_{18}$. Formed by exhaustive chlorination of tri-phenyl-benzene by means of $SbCl_5$ (Merz a. Weith, *B.* 16, 2883). Colourless needles. V. sol. hot nitrobenzene, sl. sol. ether, benzene, and alcohol. It is only slightly attacked by HNO_3 at 350°.

CHLORO-PHENYL BENZYL OXIDE $C_6H_4Cl.O.CH_2Ph$. [71°]. From phenyl benzyl oxide and Cl in presence of HgO (Sintenis, *A.* 161, 338). Long needles (from alcohol).

TRI-CHLORO-DI-PHENYL-BUTANE $C_{16}H_{15}Cl_3$ *i.e.* $CH_3.CHCl.CCl_2.CHPh_2$. [80°]. S. (ether) 50; (alcohol) 2. From tri-chloro-butyric aldehyde, benzene, and H_2SO_4 (Hepp, *B.* 7, 1420). Monoclinic prisms (from ether-alcohol).

TRI-CHLORO-DI-PHENYL-BUTANE DISULPHONIC ACID $C_{16}H_{13}Cl_3(SO_3H)_2$. From $C_{16}H_{15}Cl_3$ and fuming H_2SO_4 (Hepp, *B.* 7, 1420).—BaA″.

CHLORO-DI-PHENYL-*tert*-BUTYL ALCOHOL $CClPh_2.CMe_2OH$. (239°). From liquid acetone-chloroform, benzene, and Al_2Cl_6 (Willgerodt, *J. pr.* [2] 37, 362).

Di-chloro-phenyl-*tert*-butyl alcohol $CCl_2Ph.CMe_2OH$. (217°). From acetone-chloroform, benzene, and Al_2Cl_6 (Willgerodt a. Genieser, *J. pr.* [2] 37, 367). Liquid.

CHLORO-*o*-PHENYLENE-DIAMINE $C_6H_7ClN_2$ *i.e.* $C_6H_3Cl(NH_2)_2$ [4:2:1]. [72°]. From chloro-di-nitro-benzene [39°] by reduction with tin and HCl (Laubenheimer, *B.* 9, 773). Laminæ. Fe_2Cl_6 gives a red colour and a brown pp.

Chloro-*m*-phenylene-diamine $C_6H_3Cl(NH_2)_2$ [4:3:1]. [86°]. From chloro-di-nitro-benzene [50°], tin, and HCl (Beilstein a. Kurbatoff, *A.* 197, 76). Needles (from ligroïn).

Chloro-*p*-phenylene-diamine $C_6H_3Cl(NH_2)_2$ [2:4:1]. [123·5°]. From di-chloro-nitro-aniline [188°], tin, and HCl (Witt, *B.* 8, 145). Flat needles.—B'HCl: long needles.

Di-chloro-*o*-phenylene-diamine $C_6H_2Cl_2(NH_2)_2$ [5:3:2:1]. [60·5°]. From di-chloro-nitro-aniline [100°], tin and HCl (Witt, *B.* 7, 1604). Long flexible needles (from alcohol).

Di-chloro-*p*-phenylene-diamine $C_6H_2Cl_2(NH_2)_2$ [5:2:4:1]. [164°]. Formed, together with di-methyl-*p*-phenylene-diamine and di-chloro-di-methyl-*p*-phenylene-diamine, by boiling nitroso-di-methyl-aniline with HCl (S.G. 1·2) (Möhlau, *B.* 19, 2010). Colourless glistening prisms. By $K_2Cr_2O_7$ and H_2SO_4 it is oxidised to di-chloro-quinone [159°]. The dilute HCl solution on treatment with chloride of lime yields di-chloro-quinone-di-chlorimide [134°].

Tetra-chloro-*p*-phenylene diamine $C_6Cl_4(NH_2)_2$. [218°]. Formed by boiling quinone dichlorimide with HCl (S.G. 1·2) (Krause, *B.* 12, 51). Red needles (from dilute alcohol).

DI-CHLORO-DI-PHENYLENE KETONE $C_{13}H_6Cl_2O$. [158°]. From di-chloro-fluorene by CrO_3 (Hodgkinson a. Matthews, *C. J.* 43, 170).

DI-*a*-CHLORO-PHENYLENE-DI-METHYL-DI-MALONIC ETHER $C_6H_4(CH_2CCl(CO_2Et)_2)_2$. *v. Exo-di-chloro-xylylene-malonic ether.*

TETRA-CHLORO-PHENYLENE-DI-METHYL OXIDE  $C_6Cl_4<^{CH_2}_{CH_2}>O$. [218°]. V.D. 8·6 (calc. 8·9). From tetra-chloro-phthalic acid, HI, and P at 230° (Græbe, *A.* 238, 331). Needles (from benzene).

Octo-chloro-phenylene-di-methyl oxide  $C_6Cl_4<^{CCl_2}_{CCl_2}>O$. [140°]. From tetrachloro-phthalic anhydride and PCl_5 at 200° (G.)

DI-CHLORO-PHENYLENE-(*a*)-NAPHTHYLENE-OXIDE $C_{16}H_8Cl_2O$. [245°]. Prepared by the action of PCl_5 on phenylene-(*a*)-naphthylene-oxide (Arx, *B.* 13, 1727). Fine white needles. V. sol. alcohol and ether, sl. sol. benzene.

TETRA-CHLORO-PHENYLENE OXIDE C_6Cl_4O (?) [320°]. (above 360°). Formed by distilling potassium penta-chloro-phenol C_6Cl_5OK (Merz a. Weith, *B.* 5, 461). Flat needles. V. sl. sol. alcohol and ether. Not affected by PCl_5 at 250° or by sodium-amalgam.

CHLORO-PHENYL-ETHANE *v.* CHLORO-ETHYL-BENZENE.

Chloro-di-phenyl-ethane $C_{14}H_{13}Cl$ *i.e.* $CH_2Cl.CHPh_2$. From di-chloro-di-ethyl oxide $CH_2Cl.CHCl.OEt$, benzene, and H_2SO_4 (Hepp, *B.* 6, 1439). Liquid. Splits up on distillation or treatment with alcoholic KOH into HCl and $C_{14}H_{12}$.

Di-*p*-chloro-di-phenyl-ethane $C_6H_4Cl.CH_2.CH_2.C_6H_4Cl$. *Di-chloro-dibenzyl.* [112°]. Formed by passing chlorine over a solid cake of dibenzyl (150 pts.) and iodine (1 pt.) till the cake liquefies. This is distilled and the product crystallised from alcohol (Kade, *J. pr.* [2] 19, 462). Glittering plates which feel greasy. Sol. alcohol, ether, and chloroform. Chromic mixture oxidises it to *p*-chloro-benzoic acid.

(*a*)-Di-*exo*-chloro-*s*-di-phenyl ethane $C_6H_5.CHCl.CHCl.C_6H_5$. *Stilbene* (*a*)*-chloride.* [193°]. Formed, together with the (*β*)-isomeride, by the action of PCl_5 on hydrobenzoïn (Zincke, *A.* 198, 129) and by the union of Cl with *s*-di-phenyl-ethylene (Laurent, *B.J.* 25, 620). Formed also from isohydrobenzoïn and PCl_5 (Ammann, *A.* 168, 67). Perhaps identical with the compound [180°] which is formed by heating benzylidene chloride with copper-powder at 100° (Onufrowicz, *B.* 17, 835).

Properties.—Silky needles (from alcohol), prisms (from toluene), or plates (O.). Sl. sol. boiling alcohol. May be sublimed. Alcoholic KOH forms *s*-di-phenyl-acetylene (tolane). AgOAc followed by KOH gives isohydrobenzoïn.

(*β*)-Di-*exo*-chloro-*s*-di-phenyl-ethane $C_6H_5.CHCl.CHCl.C_6H_5$. *Stilbene* (*β*)*-chloride.* [94°]. Formed as above. Thick tables. At 200° it is partially converted into the (*a*)-isomeride.

Tri-chloro-*s*-di-phenyl-ethane $C_{14}H_{11}Cl_3$. [85°]. From *s*-di-phenyl-ethylene and Cl (Laurent).

Tri-chloro-*u*-di-phenyl-ethane $CCl_3.CHPh_2$. [64°]. From chloral, benzene, and H_2SO_4 (Baeyer, *B.* 5, 1098). Small thin plates. Alcoholic KOH gives $CPh_2:CCl_2$.

Tri-chloro-*u*-di-phenyl-ethane $CH_2Cl.CH(C_6H_4Cl)_2$. From di-chloro-di-ethyl-oxide $CH_2Cl.CHCl.OEt$, chloro-benzene, and H_2SO_4 (Hepp, *B.* 7, 1419). On distillation it gives $CH_2:C(C_6H_4Cl)_2$.

Tetra-chloro-*s*-di-phenyl-ethane $C_6H_5.CCl_2.CCl_2.C_6H_5$. *Tolane tetra-chloride.* [163°].

Formation.—1. From benzil and PCl_5 (Zinin, *Z.* 1868, 718).—2. A by-product in the preparation of benzotrichloride by chlorinating toluene (Liebermann a. Homeyer, *B.* 12, 1971). 3. By heating benzotrichloride with copper-powder at 100° (Onufrowicz, *B.* 17, 833).—4. By heating benzotrichloride with benzene and copper-powder (Hanhart, *B.* 15, 901).

Properties.—Trimetric crystals; sol. benzene, hot alcohol, and ether. Gives a violet dye with dimethylaniline and $ZnCl_2$. Alcohol and zinc-dust gives (*a*) and (*β*) di-chloro-di-phenyl-ethylene.

Penta-chloro-*u*-di-phenyl-ethane $CCl_3.CH(C_6H_4Cl)_2$. [106°]. S. (95 p.c. alcohol) 10. From chloral, chlorobenzene, and H_2SO_4 (Zeidler, *B.* 7, 1181). Felted needles (from ether-alcohol). Alcoholic KOH gives $C_{14}H_8Cl_4$.

CHLORO-DI-PHENYL-ETHYLENE $C_6H_5.CCl:CH.C_6H_5$. *Chloro-stilbene.* From stilbene di-chloride and alcoholic KOH (Zinin, *A.* 149, 375). Oil.

(*a*)-Di-chloro-*s*-di-phenyl-ethylene $C_6H_5.CCl:CCl.C_6H_5$. *Tolane-(a)-di-chloride.* [143°]. Formed, together with the (*β*)-modification, by the action of powdered zinc on an alcoholic solution of tetra-chloro-di-phenyl ethane (Liebermann a. Homeyer, *B.* 12, 1973; *cf.* Zinin, *B.* 4, 289); or of iron powder on an acetic acid solution of the same body (Lachowicz, *B.* 17, 1165). Formed also by passing Cl into a solution of *s*-di-phenyl-ethylene in chloroform. Both modifications are also formed by heating benzo-trichloride with copper-powder (Hanhart, *B.* 15, 899), and by heating *s*-di-phenyl-ethylene with PCl_5 at 180° (Limpricht a. Schwanert, *B.* 4, 379). Trimetric tables or prisms. Sl. sol. alcohol. Alcoholic KOH at 180° gives *s*-di-phenyl-acetylene (tolane).

(β)-Di-chloro-*s*-di-phenyl-ethylene $C_6H_5.CCl:CCl.C_6H_5$. *Tolane-(β)-di-chloride.* [63°]. Formed as above. Long needles. More soluble in alcohol than the (α)-modification. The (α) and (β) modifications can be partially changed into one another by distillation.

Di-chloro-*u*-di-phenyl-ethylene $CCl_2:CPh_2$. [80°]. Formed by passing Cl into *u*-di-phenyl-ethylene and distilling the resulting $CCl_2.CClPh_2$ (Hepp). Formed also from $CCl_3.CHPh_2$ by boiling with alcoholic KOH (Baeyer, *B.* 6, 223). Monoclinic prisms (from alcohol).

Di-chloro-di-phenyl-ethylene $C_6H_4Cl.CH:CH.C_6H_4Cl$. [170°]. Formed by passing Cl in excess into melted dibenzyl (Kade, *J. pr.* [2] 19, 466). Needles or plates (from alcohol).

Di-chloro-*u*-di-phenyl-ethylene $CH_2:C(C_6H_4Cl)_2$. (283°). Formed by distilling $CH_2Cl.CH(C_6H_4Cl)_2$ (Hepp, *B.* 7, 1419).

Tri-chloro-*s*-di-phenyl-ethylene $C_{14}H_9Cl_3$. Two modifications are formed by treating *s*-di-phenyl-acetylene (tolane) with PCl_5 (Limpricht a. Schwanert, *B.* 4, 379).

(α)-Modification: [137°–145°]; needles.

(β)-Modification: [150°]; prisms.

Tetra-chloro-di-phenyl-ethylene $CCl_2:C(C_6H_4Cl)_2$. [89°]. From $CCl_3.CH(C_6H_4Cl)_2$ and alcoholic KOH (Zeidler, *B.* 7, 1181).

ω-TRI-CHLORO-DI-PHENYL-ETHYLIDENE DIAMINE $C_{14}H_{13}N_2Cl_3$ *i.e.* $CCl_3.CH(NHC_6H_5)_2$. [101°]. Formed by the action of aniline on chloral (Wallach, *B.* 5, 251; *A.* 173, 277). Tabular crystals (from alcohol). Insol. water. Decomposes at 150°. Boiling with alkalis forms phenyl carbamine.—$B'_2H_2PtCl_6$ (Amato, *B.* 9, 198).

DI-CHLORO-DI-PHENYL-GUANIDINE $C_{13}H_{11}Cl_2N_3$ *i.e.* $NH:C(NH.C_6H_4Cl)_2$. From aqueous di-phenyl-guanidine hydrochloride and Cl (Hofmann, *A.* 67, 147). Laminæ (from alcohol).—$B'_2H_2PtCl_6$.

Di-chloro-di-phenyl-guanidine $NH:C(NH.C_6H_4Cl)_2$. [141°]. From di-chloro-di-phenyl-thio-urea, PbO, and NH_3 (Losanitsch, *Bl.* [2] 32, 170). Needles. Perhaps identical with the preceding.

Tri-*p*-chloro-tri-phenyl-guanidine $C_{19}H_{14}Cl_3N_3$ *i.e.* $C_6H_4Cl.N.C(NH.C_6H_4Cl)_2$. Formed by adding iodine to an alcoholic solution of di-chloro-di-phenyl-thio-urea $CS(NH.C_6H_4Cl)_2$ (Beilstein a. Kurbatoff, *A.* 176, 51). Slender needles (from CS_2).—B'HCl.—B'HI: [255°].—$B'_2H_2SO_4$.

CHLORO-DI-PHENYL-KETONE *v.* CHLORO-BENZOPHENONE.

CHLORO-PHENYL MERCAPTAN $C_6H_4Cl.SH$. [54°]. From chloro-benzene sulphonic chloride, zinc, and dilute H_2SO_4 (Otto, *A.* 143, 109). Four-sided trimetric tables (from alcohol).—$(C_6H_4Cl.S)_2Pb$: yellow pp.

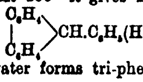
***p*-CHLORO-PHENYL MERCAPTURIC ACID** $C_{11}H_{12}ClNSO_3$ *i.e.* $CH_3.CO.NH.CMe(S.C_6H_4Cl).CO_2H$. [154°]. Found in the urine of a dog after it had taken chloro-benzene (Jaffé, *B.* 12, 1092). Colourless leaflets or tables. V. sl. sol. ether, v. sol. alcohol.

β-CHLORO-β-PHENYL-METHACRYLIC ACID $C_{10}H_9ClO_2$ *i.e.* $C_6H_5.CCl:CMe.CO_2H$. [116°]. From methyl-benzoyl-acetic ether, $POCl_3$, and PCl_5 (Perkin, jun., a. Calman, *C. J.* 49, 159). Needles, v. sol. alcohol, ether, benzene, and HOAc, m. sol. cold light petroleum.—AgA'.

CHLORO-DI-PHENYL-METHANE $(C_6H_5)_2CHCl$. *Di-phenyl-carbinyl chloride.* [14°]. From di-phenyl-carbinol and HCl (Engler a. Bethge, *B.* 7, 1128). Decomposed by heat into HCl, tetra-phenyl-ethylene, and tetra-phenyl-ethane (Anschütz, *A.* 235, 220).

Di-chloro-di-phenyl-methane $(C_6H_5)_2CCl_2$. *Benzophenone chloride.* (305° i.V.). S.G. $\frac{18.5}{}$ 1·235. From benzophenone and PCl_5 (Behr, *B.* 3, 752). Liquid. Decomposed by distillation. Warm water reconverts it into benzophenone. KHS gives $(C_6H_5)_2CS$. Heating with silver forms $Ph_2C.CPh_2$. Aniline forms $Ph_2C:NPh$. Di-methyl-aniline gives $Ph_2CH.C_6H_4NMe_2$ (Pauly, *A.* 187, 198).

Chloro-tri-phenyl-methane $(C_6H_5)_3CCl$. *Tri-phenyl carbinyl chloride.* [105°–115°]. From tri-phenyl-carbinol and PCl_5 (Hemilian, *B.* 7, 1207). Formed also by the action of benzene on CCl_4 in presence of Al_2Cl_6 (Friedel a. Crafts, *A. Ch.* [6] 1, 502). At 250° it gives HCl, tri-phenyl-methane, and



$\begin{matrix} C_6H_4 \\ | \\ C_6H_4 \end{matrix}\!\!>CH.C_6H_5$

(Hemilian, *B.* 11, 837). Hot water forms tri-phenyl-carbinol.

DI-CHLORO-TRI-PHENYL-METHANE CARBOXYLIC ACID $(C_6H_4Cl)_2CH.C_6H_4.CO_2H$. [206°]. From di-chloro-di-phenyl-phthalide and boiling alcoholic NaOH; the resulting $(C_6H_4Cl)_2C(OH).C_6H_4.CO_2H$ being reduced with zinc-dust and aqueous NaOH (Baeyer, *A.* 202, 84). Six-sided tables (from alcohol). CrO_3 gives di-chloro-phenyl-oxanthranol.

Tetra-chloro-di-phenyl-methane carboxylic acid *v.* TETRA-CHLORO-*o*-BENZYL-BENZOIC ACID.

DI-CHLORO-DI-PHENYL-METHANE SULPHONIC CHLORIDE $C_{13}H_8S_2O_4Cl_4$ *i.e.* $CCl_2(C_6H_4SO_2Cl)_2$. [129°]. From $CO(C_6H_4SO_2Cl)_2$ and PCl_5 (Bockmann, *B.* 8, 992). Amorphous; sl. sol. alcohol.

TETRA-CHLORO-DI-PHENYL-METHYL-AMINE $C_{13}H_9NCl_4$ *i.e.* $(C_6H_3Cl_2)_2NMe$. [97°]. Formed by passing Cl into a solution of NPh_2Me in HOAc (Gnehm, *B.* 8, 1040). Prisms.

CHLORO-PHENYL-METHYL-KETONE *v.* CHLORO-ACETOPHENONE.

DI-CHLORO-PHENYL-OXAMIC ACID $C_6H_3Cl_2.NH.CO.CO_2H$. [122°]. S. ·124 at 25°. Prepared by boiling tetra-chloro-oxanilide (4 gr.), alcohol (125 cc.) and KHO (5 gr.) for 10 minutes (Dyer a. Mixter, *Am.* 8, 354). White fibres. Sol. alcohol and ether. KHO solution gives di-chloro-aniline [63°].

Salts.—KA': white hair-like fibres.

TETRA-CHLORO-DI-PHENYL-OXAMIDE $C_2O_2(NH.C_6H_3Cl_2)_2$ [1:2:4]. *Tetra-chloro-oxanilide.* [c. 255°]. From oxanilide by chlorination in HOAc (Dyer a. Mixter, *Am.* 8, 349). White fibres.

DI-CHLORO-PHENYL-OXANTHRANOL

$C_{20}H_{12}Cl_2O_2$ *i.e.*
$CO<\begin{smallmatrix}C_6H_4\\C_6H_3Cl\end{smallmatrix}>C(OH).C_6H_4Cl$.

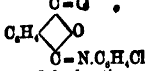
Phenol-phthalideïn-chloride. [156°]. From di-oxy-phenyl-oxanthranol (phenol - phthalideïn) and PCl_5 at 120° (Baeyer, *A.* 202, 100). Silky needles (from alcohol).

CHLORO-PHENYL-PHOSPHORIC ACID

$C_6H_6ClPO_4$ *i.e.* $C_6H_4ClO.PO(OH)_2$. [81°]. Formed together with *p*-di-chloro-benzene by treatment of phenol *p*-sulphonic acid and PCl_5; the resulting $C_6H_4Cl.O.POCl_2$ being decomposed by water (Kekulé, *B.* 5, 877; 6, 944).—BaA″.

Chloride $C_6H_4Cl.O.POCl_2$. (265°).

***p*-CHLOROPHENYL PHTHALIMIDE**



[194°-195° uncor.]. Prepared by heating *p*-chloro-aniline with phthalic anhydride (Gabriel, *B.* 11, 2260). Long fine needles. Sol. hot alcohol, C_6H_6, and acetic acid.

α-CHLORO-α-PHENYL-PROPIONIC ACID

$C_9H_9ClO_2$ *i.e.* $CH_3.CClPh.CO_2H$. *Chloro-hydro-atropic acid* [73°]. From atrolactic acid and HCl in the cold (Merling, *A.* 209, 19). Small prisms, m. sol. hot water, sl. sol. cold water. Volatile with steam. Attacks the mucous membrane. Decomposes at 110°. Boiling alkaline carbonates form no styrene.

β-Chloro-α-phenyl-propionic acid

$CH_2Cl.CHPh.CO_2H$. *Chloro-hydratropic acid.* [89°]. Possibly identical with the preceding. Prepared by the action of HCl on the cyan-hydrin obtained from acetophenone and HCN (Spiegel, *B.* 14, 235). From tropic acid and PCl_5 followed by water (Ladenburg, *A.* 217, 77). Formed also by the union of atropic acid with fuming HCl at 100° (Merling, *A.* 209, 3). Colourless prisms. Sol. alcohol, ether, and benzene, sl. sol. water and ligroin. On boiling with aqueous NaOH it gives atropic acid. On heating with Na_2CO_3 solution to 130° tropic acid is formed. Boiling aqueous Na_2CO_3 forms tropic acid and a little styrene.

***o*-Chloro-β-phenyl-propionic acid**

$C_6H_4Cl.C_2H_4.CO_2H$. *o-Chloro-hydrocinnamic acid.* [97°]. Needles or plates. Formed by reduction of *o*-chloro-cinnamic acid with HI and P (Gabriel a. Herzberg, *B.* 16, 2037).

***m*-Chloro-β-phenyl-propionic acid**

$C_6H_4Cl.C_2H_4.CO_2H$. *m - Chloro - hydrocinnamic acid.* [78°]. White easily soluble plates. Formed by reduction of *m*-chloro-cinnamic acid with HI and P (G. a. H.).

***p*-Chloro-phenyl-propionic acid.**

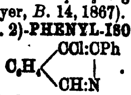
$C_6H_4Cl.C_2H_4.CO_2H$. *p-Chloro-hydrocinnamic acid* [124°]. Formed by reduction of *p*-chloro-cinnamic acid (G. a. H.).

β-Chloro-β-phenyl-propionic acid

$C_6H_5.CHCl.CH_2.CO_2H$. [126°]. From β-oxy-β-phenyl-propionic acid and fuming HCl (Glaser, *A.* 147, 95). Very slowly formed by combination of cinnamic acid with HCl in conc. aqueous solution (Erlenmeyer, *B.* 14, 1867). Laminæ. Split up by heat into HCl and cinnamic acid; and by aqueous Na_2CO_3 into CO_2, HCl, and styrene.

αβ-Di-chloro-β-phenyl-propionic acid

$C_6H_5.CHCl.CHCl.CO_2H$. [164°]. White plates. Formed by leading Cl into a CS_2 solution of cinnamic acid. With aqueous Na_2CO_3 it gives ω-chloro-styrene (Erlenmeyer, *B.* 14, 1867).

(*Py.* 1)-CHLORO-(*Py.* 2)-PHENYL-ISOQUINOLINE $C_{15}H_{10}ClN$ *i.e.*


$C_6H_4<\begin{smallmatrix}CCl:CPh\\ |\\ CH:N\end{smallmatrix}$. [70°].

Obtained by reduction of (*Py.* 1:4)-di-chloro-(*Py.* 2)-phenyl-isoquinoline with HI and P. Glistening pillars. Salts.—B′HCl: small thick crystals.—$B'_2H_2Cl_2PtCl_4$: orange yellow needles (Gabriel, *B.* 18, 3475).

(*Py.* 4)-Chloro-(*Py.* 2)-phenyl-isoquinoline

$C_{15}H_{10}ClN$ *i.e.*
$C_6H_4<\begin{smallmatrix}CH:CPh\\ |\\ CCl:N\end{smallmatrix}$. [78°]. Prepared by boiling (*Py.* 4)-oxy-(*Py.* 2)-phenyl-isoquinoline (isobenzalphthalimidine) with $POCl_3$ (2 pts.). It is also formed by heating the same compound with PCl_5 at 100°-130°. Flat pointed needles. Sol. alcohol, v. sol. benzene, ether, petroleum-spirit, chloroform, and CS_2, insol. water. Heated with HI and P at 170° it is reduced to phenyl-isoquinoline (Gabriel, *B.* 18, 3473).

(*Py.* 1:4)-Di-chloro-(*Py.* 2)-phenyl-isoquinoline $C_{15}H_9Cl_2N$ *i.e.*
$C_6H_4<\begin{smallmatrix}CCl:CPh\\ |\\ CCl:N\end{smallmatrix}$ [163°]. Obtained by heating (*Py.* 4)-oxy-(*Py.* 2)-phenyl-isoquinoline (isobenzalphthalimidine) with PCl_5 at 100°. By boiling with HI and P it is reduced to (*Py.* 1)-chloro-(*Py.* 2)-phenyl-isoquinoline [70°] (Gabriel, *B.* 18, 3473).

TRI-CHLORO-TRI-PHENYL-ROSANILINE

$C_6H_4Cl.NH.C_6H_3Me.C(OH)(C_6H_4.NH.C_6H_4Cl)_2$.

The *o*-, *m*- and *p*-compounds are formed by heating rosaniline with *o*-, *m*-, or *p*-chloraniline in presence of benzoic acid. They dye silk various shades of bluish violet (Heumann a. Heidlberg, *B.* 19, 1992).

DI-CHLORO-DI-PHENYL SULPHIDE

$(C_6H_4Cl)_2S$. [89°]. From 'thio-aniline' $S(C_6H_4NH_2)_2$ by displacement of NH_2 by Cl through the diazo- reaction (Krafft, *B.* 7, 1165).

Di-chloro-di-phenyl di-sulphide $(C_6H_4Cl)_2S_2$. [71°]. From $C_6H_4Cl.SH$ and HNO_3 (S.G. 1·12) (Otto, *A.* 143, 111). Tables. Zinc and dilute H_2SO_4 reconvert it into chloro-phenyl mercaptan.

CHLORO-DI-PHENYL SULPHONE

$C_6H_5.SO_2.C_6H_4Cl$. [92°]. (889°). From benzene sulphonic chloride, benzene, and Al_2Cl_6; the yield is 87 p.c. of the theoretical (Beckurts a. Otto, *B.* 11, 2067; 19, 2418). Leaflets. Insol. water; v. sol. hot alcohol.

Di-*o*-chloro-di-phenyl sulphone $(C_6H_4Cl)_2SO_2$. [174°]. (360°). Formed in sulphonating *o*-di-chloro-benzene (Friedel a. Crafts, *A. Ch.* [6] 10, 414). Crystals.

Di-chloro-di-phenyl-sulphone $C_{12}H_8Cl_2SO_2$. (above 300°). Formed by chlorinating di-phenyl-sulphone in diffused daylight at 100° in presence of iodine (Otto a. Gruber, *A.* 149, 180). Oil.

Di-*p*-chloro-di-phenyl-sulphone $(C_6H_4Cl)_2SO_2$. [141°] (O.); [147°] (B. a. O.). From chloro-benzene and SO_3 (Otto, *A.* 145, 28). Also from chloro-benzene and $ClSO_3H$ (Beckurts a. Otto, *B.* 11, 2065). Plates. H_2SO_4 at 150° gives chloro-benzene sulphonic acid. Sodium amalgam in alcoholic solution gives benzene, chloro-benzene sulphonic acid, and benzene sulphonic acid.

CHLORO-PHENYL-THIO-CARBAMIC ETHER $C_6H_4Cl.NHCS.OEt$. [103°]. Formed by adding iodine to an alcoholic solution of di-chloro-di-phenyl-thio-urea (Beilstein a. Kurbatoff, *A.* 176, 52). Needles.

***o*-CHLORO-PHENYL-THIO-CARBIMIDE** $C_6H_4(Cl).NCS$ [1:2]. [45°]. (250°). Crystalline solid. Prepared by the action of P_2O_5 on the corresponding urea derived from *o*-chloro-nitro-benzene (Hofmann, *B.* 13, 14). An isomeride is chloro-methenyl-amido-phenyl-mercaptan $C_6H_4\left\langle\begin{matrix}N\\S\end{matrix}\right\rangle CCl$.

***m*-Chloro-phenyl-thiocarbimide** $C_6H_4(Cl).NCS$ [1:3]. (250°). Prepared by the action of P_2O_5 on the corresponding urea [122°] obtained from *m*-chloro-aniline and CS_2 (Hofmann, *B.* 13, 13). Liquid.

***p*-Chloro-phenyl-thio-carbimide** $C_6H_4(Cl).NCS$ [1:4]. [45°]. (250°). Crystalline solid. Prepared by the action of CS_2 on *p*-chloro-aniline and decomposition of the resulting di-chloro-phenyl-urea (Hofmann, *B.* 13, 18; Beilstein a. Kurbatoff, *A.* 176, 51; Losanitsch, *B.* 5, 156).

DI-*o*-CHLORO-DI-PHENYL-THIO-UREA $C_{13}H_{10}Cl_2N_2S$ *i.e.* $CS(NH.C_6H_4Cl)_2$. [146°]. From *o*-chloro-aniline and CS_2 (Hofmann, *B.* 13, 14).

Di-*m*-chloro-di-phenyl-thio-urea [122°] (H.).

Di-*p*-chloro-di-phenyl-thio-urea [168°]. S. (in CS_2) ·0264 at 13·7° (Beilstein, *A.* 176, 47). From *p*-chloro-aniline, CS_2, and alcohol (Losanitsch, *B.* 5, 156; *Bl.* [2] 32, 170). Iodine acting on its alcoholic solution forms di-chloro-di-phenyl-urea, tri-chloro-tri-phenyl-guanidine, chloro-phenyl thio-carbimide, and chloro-phenyl-carbamic ether.

TRI-CHLORO-PHENYL-TOLYL-ETHANE CARBOXYIC ACID $C_{16}H_{13}Cl_3O_2$ *i.e.* $CH_3.C_6H_4.CH(CCl_3).C_6H_4.CO_2H$. [174°]. From $(CH_3.C_6H_4)_2CH.CCl_3$ and chromic mixture (O. Fischer, *B.* 7, 1192). Tables (from alcohol). Alkalis give $CH_3.C_6H_4C(CCl_2).C_6H_4.CO_2H$.

DI-CHLORO-PHENYL-TOLYL-KETONE CARBOXYLIC ACID *v.* DI-CHLORO-TOLUYL-BENZOIC ACID.

ω-CHLORO-PHENYL-TOLYL-METHANE $CH_2Cl.C_6H_4.CH_2.C_6H_5$. A mixture of the *o*- and *p*- varieties of this body is one of the products of the action of benzyl chloride on water at a high temperature, the reaction being as follows: $2C_6H_5.CH_2Cl = HCl + CH_2Cl.C_6H_4.CH_2.C_6H_5$. The mixture on oxidation gives *o*- and *p*-benzoyl-benzoic acid (Senff, *A.* 220, 249).

DI-*p*-CHLORO-DI-PHENYL-UREA $(C_6H_4Cl.NH)_2CO$. A secondary product in the preparation of *p*-chloro-phenyl thiocarbimide by the action of P_2O_5 or of iodine on the corresponding thio-urea (Beilstein a. Kurbatoff, *A.* 176, 46). Long needles (from HOAc). Volatilises at 270°.

TRI-CHLORO-PHLOROGLUCIN $C_6H_3Cl_3O_3$. [129°]. Formed by passing chlorine into a solution of phloroglucin in HOAc until the liquid ceases to give a red colour with wood (Webster, *C. J.* 47, 428; Hazura a. Benedikt, *M.* 6, 706). Slender needles (containing 3aq). Dilute HNO_3 gives oxalic acid. Chlorine, in presence of CCl_4, gives chlorinated acetic aldehyde and tri-chloro-acetic acid. When chlorine is passed into an aqueous solution of phloroglucin there is formed di-chloro-acetic acid.

Hexa-Hydride $C_6H_9Cl_3O_3$. [125°]. From hexa-bromo-phloroglucin dibromide, tin, and HCl (H. a. B.). Needles (containing 3aq).

CHLORO-PHLORONE *v.* CHLORO-XYLOQUINONE.

***u*-CHLORO-PHTHALIC ACID** $C_8H_5ClO_4$ *i.e.* $C_6H_3Cl(CO_2H)_2$ [4:2:1]. [148°] (C. a. D.; G. a. R.; C. a. M.); [130°] (I.); [c. 134°] (K.).

Formation.—1. By oxidation of (ε)-di-chloro-naphthalene [135°] (Alén, *Bl.* [2] 36, 434), of chloro-(β)-naphthol (Claus a. Dehne, *B.* 15, 320), of the two chloro-toluic acids [130°] and [166°] (Krüger, *B.* 18, 1758), of ('β')-di-chloro-(α)-naphthoquinone (Claus a. Müller, *B.* 18, 3076), and of chloro-di-ethyl-benzene (Istrati, *A. Ch.* [6] 6, 413).—2. By saponifying the chloride which may be formed by the action of PCl_5 on the tri-chloride of sulpho-phthalic acid $O\left\langle\begin{matrix}CCl_2\\CO\end{matrix}\right\rangle C_6H_3.SO_2Cl$ (Rée, *A.* 233, 236).

Properties.—Small needles. V. sol. water and alcohol; m. sol. dilute HCl, chloroform, and CS_2, sl. sol. benzene, insol. ligroin. With resorcin it gives a chloro-fluoresceïn.

Salts.—K_2A'': large needles, v. sol. water.—BaA'': amorphous; sl. sol. water.—$BaH_2A''_2$: small needles, sl. sol. water.—CaA'': scales, sl. sol. water.—Ag_2A'': white pp.

Anhydride $C_6H_3Cl\left\langle\begin{matrix}CO\\CO\end{matrix}\right\rangle O$. [95°] (C. a. D.); [97°] (G. a. R.; K.); [114°] (I.). Formed by heating the acid. Triclinic needles (by sublimation).

Methyl ether Me_2A''. [37°]. Needles.

Ethyl ether Et_2A''. [−20°]. (c. 303°) (Graebe a. Rée, *C. J.* 49, 528).

Chloride $C_6H_3Cl\left\langle\begin{matrix}CCl_2\\CO\end{matrix}\right\rangle O$. (276° uncor.). Liquid.

Imide $C_6H_3Cl\left\langle\begin{matrix}CO\\CO\end{matrix}\right\rangle NH$. [211°]. From the anhydride and NH_3 (Rée, *A.* 233, 236).

***c*-Chloro-phthalic acid** $C_6H_3Cl(CO_2H)_2$ [3:2:1]. [184°] (G.); [181°] (K.). S. 2·16 at 14°.

Formation.—1. By oxidation of chloro-toluic acid [154°] with $KMnO_4$ (Krüger, *B.* 18, 1758).—2. By oxidation of (γ)-di-chloro-naphthalene [107°] with CrO_3 in HOAc (Guareschi, *G.* 17, 121; *B.* 19, 134).

Properties.—Long needles; sl. sol. cold, v. sol. hot, water; v. sol. alcohol and ether. Gives the anhydride on melting. Heated with phenol and conc. H_2SO_4 it gives a phthaleïn which dissolves in alkalis forming a violet solution.

Salts.—BaA'' aq: long silky needles, v. sol. cold, sl. sol. hot, water. By boiling with water it is converted into an insoluble crystalline powder BaA'' aq.—Ag_2A'': crystalline pp.

Anhydride $C_6H_3Cl\left\langle\begin{matrix}CO\\CO\end{matrix}\right\rangle O$. [123°]. Needles (by sublimation). By chlorination of phthalic acid Auerbach (*J.* 1880, 852) obtained an (impure?) phthalic acid [150°] whose anhydride melted at 143°.

Di-chloro-phthalic acid $C_6H_2Cl_2(CO_2H)_2$. Formed by oxidation of the tri-chloro-naphthalene [90°] (from (β)-naphthol-(β)-di-sulphonate and PCl_5), by heating with dilute HNO_3 (S.G. 1·16) at 210°. Syrup. Could not be obtained crystallised although apparently pure.

Salts.—The Na and K salts are excessively sol. water.—A″Ba: v. sol. amorphous solid.—A″Ag_2: white pp., nearly insol. cold water.—A″Pb: insol. white pp. (Claus a. Schmidt, *B.* 19, 3175).

(β)-Di-chlorophthalic acid $C_6Cl_2H_2(CO_2H)_2$. [118°]. Formed by oxidation of a chlorinated naphthalene (Graebe a. Le Royer, *A.* 238, 350). V. e. sol. hot water, m. sol. cold water or alcohol.

Salts.—$(NH_4)_2$A″.—Ag_2A″.—CaA″ 4aq.—BaA″ 2aq.

Ethers.—Et_2A″ [60°].—EtHA″ [75°–85°].—$Et(NH_4)$A″.

Anhydride $C_6Cl_2H_2C_2O_3$. [c. 151°]. (340°).

Chloride $C_6Cl_2H_2C_2O_2Cl_2$. [below 50°]. (c. 314°).

Tetrachloride $C_6Cl_2H_2C_2OCl_4$. [117°]. (above 300°).

Imide $C_6Cl_2H_2C_2O_2NH$. [191°]. Reduced by Zn and HCl to dichlorophthalimidine [210°].

Di-chloro-phthalic acid $C_6H_2Cl_2(CO_2H)_2$. [183°]. Formed by oxidation of the di-chloro-*o*-xylene [4°] by dilute HNO_3 (Claus a. Kautz, *B.* 18, 1370). Formed also by oxidation of ('β')-di-chloro-naphthalene (Atterberg, *B.* 10, 547); and by boiling di-chloro-naphthalene tetrachloride with HNO_3 (Faust, *A.* 160, 64). Prisms; v. sol. hot water, alcohol, and ether.

Salts.—BaA″ aq.—CaA″ 4aq: prisms, sl. sol. water.

Anhydride $C_6H_2Cl_2C_2O_3$. [187°].

Tri-chloro-phthalic acid $C_6HCl_3(CO_2H)_2$. Formed by oxidation of tri-chloro-*o*-xylene [93°] by dilute HNO_3 (Claus a. Kautz, *B.* 18, 1370). Formed also by the action of conc. HNO_3 on (β)-penta-chloro-naphthalene (Atterberg a. Widmann, *B.* 10, 1841). Yellowish-white mass; converted by heat into the anhydride.

Anhydride [157°]. Needles.

Tetra-chloro-phthalic acid $C_6Cl_4(CO_2H)_2$. [250°]. S. ·57 at 14°, 3·03 at 99°.

Formation.—1. From (α)-penta-chloro-naphthalene and dilute HNO_3 at 190° (Graebe, *A.* 149, 18).—2. Together with penta-chloro-(α)-naphthoquinone, by oxidation of hepta-chloro-naphthalene [194°] with HNO_3 (1·5 S.G.) at 100° (Claus a. Wenzlik, *B.* 19, 1166).

Preparation.—Phthalic anhydride (5 kilos.) is heated with $SbCl_5$ (30 kilos.) at 200°, and chlorine is passed in for 10 hours. The product is distilled (Gnehm, *A.* 238, 319).

Properties.—Plates (from water). V. sol. alcohol and ether, sl. sol. benzene and chloroform.

Reactions.—1. Converted by *heat* into H_2O and its anhydride.—2. Calcium salt gives octo-chloro-anthraquinone (in small quantity) when distilled (Kircher, *B.* 17, 1170).—3. *Sodium amalgam* reduces it in dilute alcoholic solution to phthalic acid (Claus a. Spruck, *B.* 15, 1401); the reduction is better performed in aqueous solution, but hydrophthalic acid and other products are also formed (Graebe, *A.* 238, 323).—4. HI and P at 230° give tetra-chloro-*s*-phenylene-di-methyl oxide, $C_6Cl_4{<}\begin{matrix}CH_2\\CH_2\end{matrix}{>}O$, and some tetra-chloro-phthalide $C_6Cl_4{<}\begin{matrix}CH_2\\CO\end{matrix}{>}O$. The latter body is also produced by the action of zinc-dust and glacial acetic acid.—5. PCl_5 forms $C_6Cl_4{<}\begin{matrix}CCl_2\\CO\end{matrix}{>}O$ and $C_6Cl_4{<}\begin{matrix}CCl_2\\CCl_2\end{matrix}{>}O$.

Salts.—K_2A″.—BaA 2½aq.—BaA′$_2$ 3½aq (Tust, *B.* 21, 1582).—CuA″ 2aq.—Ag_2A″.

Ethers.—Et_2A″. [60·5°].—EtHA″. [95°].—Me_2A″. [92°].

Anhydride $C_6Cl_4{<}\begin{matrix}CO\\CO\end{matrix}{>}O$. [245°].

Chloride $C_6Cl_4{<}\begin{matrix}CCl_2\\CO\end{matrix}{>}O$. [118°]. (336°) at 733 mm. From the anhydride and PCl_5 at 220°.

Tetrachloride $C_6Cl_4{<}\begin{matrix}CCl_2\\CCl_2\end{matrix}{>}O$. [140°].

Imide $C_6Cl_4C_2O_2NH$. From NH_3 and the anhydride.

(γ)-CHLORO-ISO-PHTHALIC ACID $C_6H_3Cl(CO_2H)_2$. [278°]. S. ·026 at 15°.

Preparation.—A solution of amido-iso-phthalic acid in HCl is mixed at 0° with $NaNO_2$, and the pp. of the hydrochloride of diazo-iso-phthalic acid is gently warmed with HCl. Crystallised from water (Beyer, *J. pr.* 133, 506).

Properties.—Slender needles (from water). When dried over H_2SO_4 they contain water (½aq). V. sl. sol. hot water.

Salts.—The neutral potassium salt gives no pp. with solutions of salts of Ca, Sr, Ba, Mg, Zn, Mn, Co, Ni, nor with $HgCl_2$. It gives, with $CdSO_4$, bulky white pp.; Fe_2Cl_6 light brown pp.; $Pb(OAc)_2$ and $AgNO_3$, white pps. soluble in hot water. $CuSO_4$, blue pp.; $Hg_2(NO_3)_2$, white gelatinous pp. A″K_2: needles arranged like ferns.—A″Na_2.—A″Mg 7aq.—A″Ca 2aq. S. 3·54 at 15°.—A″Sr aq. S. ·929 at 15°.—A″Ba 2aq. S. 1·41 at 15°.—A″Cd. S. ·303 at 15°.—A″Ag_2. Gelatinous pp. Crystallises in small needles (from hot water).

Ethyl ether A″Et_2 [45°]. Short prisms (from ether).

Chloro-tere-phthalic acid *v.* CHLORO-TEREPHTHALIC ACID.

DI-CHLORO-PHTHALIDE $C_6H_2Cl_2{<}\begin{matrix}CH_2\\CO\end{matrix}{>}O$. [122°]. From the chloride of di-chloro-phthalic acid $C_6H_2Cl_2{<}\begin{matrix}CCl_2\\CO\end{matrix}{>}O$ by reducing with Zn and HCl (Le Royer, *A.* 238, 355). Also from nitroso-di-chloro-phthalimidine and alkalis. Crystals (from alcohol).

Di-chloro-phthalide $C_6H_2Cl_2{<}\begin{matrix}CH_2\\CO\end{matrix}{>}O$ [1:4:5:6]. [163°]. Formed, together with di-chloro-(α)-naphthoquinone by oxidation of di-chloro-naphthalene [68°], with CrO_3 and glacial acetic acid. Short prisms or flat needles. Sol. alcohol and ether, v. sl. sol. water. Sublimable. It does not react with hydroxylamine (Guareschi, *B.* 19, 1155).

Tetra-chloro-phthalide $C_6Cl_4{<}\begin{matrix}CH_2\\CO\end{matrix}{>}O$. [208·5°]. From tetrachlorophthalic anhydride, glacial HOAc and zinc-dust (Graebe, *A.* 238, 330). V. sl. sol. cold alcohol; insol. Na_2CO_3Aq; sol. boiling NaOH and reppd. by acids unaltered.

CHLORO-PHTHALIMIDE *v. Imide of* CHLORO-PHTHALIC ACID.

DI-CHLORO-PHTHALIMIDINE $C_6H_2Cl_2{<}\begin{matrix}CH_2\\CO\end{matrix}{>}NH$. [210°]. From di-chloro-phthalimide, tin, and HCl (Royer, *A.* 238, 356).

Crystals (from chloroform). Gives a nitroso-derivative.

TETRACHLORO-DIPHTHALYL $C_{16}H_4Cl_4O_4$

$i.\,e.\ C_6Cl_4\left\langle\begin{array}{c}C = = = = C\\ CO\!>\!O\quad O\!<\!CO\end{array}\right\rangle C_6H_4$. Formed by the condensation of tetra-chloro-phthalide and phthalic anhydride without the use of sodium acetate (Graebe a. Guye, *A.* 233, 245). Brownish yellow powder; insol. alcohol, glacial acetic acid and toluene; sol. chloroform, aniline and phenol.

CHLOROPHYLL—the peculiar substance to which the green colour of leaves and other parts of plants is due—was first examined by Pelletier and Caventou, who called it *chlorophyll*. From the chemist's point of view it is simply an organic colouring matter, like indigo or alizarin.

It is important to bear this in mind, since much confusion and misunderstanding have arisen from the term chlorophyll having been applied to distinct things. Some chemists understand by chlorophyll the sum of the coloured constituents of leaves insoluble in water, and it has accordingly been proposed to call that constituent the colour of which inclines more to blue, *Kyanophyll*, while that constituent or group of constituents which gives solutions of a yellow or greenish-yellow tint should be named *Xanthophyll*. In works on vegetable physiology the term chlorophyll is sometimes applied to the complex of substances contained in living green cells, which take part in the process of assimilation and of which the colouring matter constitutes a portion, and chemists, following this example in giving a name to the whole which should have been confined to one part, have been led to ascribe to chlorophyll properties which no mere chemical substance can possibly possess. In order to avoid confusion it should therefore be understood that in using the term chlorophyll we mean simply the substance—or it may be mixture of substances—to which the pure green colour of ordinary healthy leaves and of other vegetable organs, such as unripe fruit, is due. The appearance in leaves of any colour other than green, such as red, yellow, or purple, would indicate the presence of some substance accompanying the chlorophyll and disguising its colour or even replacing it entirely.

Chlorophyll is invariably present in vegetable cells in which the process of assimilation, *i.e.* the formation of organic matter from CO_2 and H_2O with elimination of O, is going on. Parasitic and other plants, such as fungi, which obtain their nutriment ready-formed from other organisms or from decaying organic matter, and do not decompose CO_2 in the same way as the majority of plants, contain no chlorophyll. Plants or shoots grown in the dark from seeds or tubers are also devoid of chlorophyll; they grow at the expense of the matter stored up in the seed or tuber, and when this is exhausted they die. The appearance of chlorophyll in etiolated plants on exposure to light indicates the commencement of assimilation. It is certain, therefore, that chlorophyll plays some part in the process of assimilation, and that its presence is essential, but how it acts in assisting the process is unknown, its physical and chemical properties, so far as they are known to us, affording no certain clue to the solution of the problem. In the green cells of plants the chlorophyll is found associated with the protoplasmic constituent from which it may be easily separated by treatment with alcohol or ether. The green corpuscles seen in vegetable cells are in fact masses of albuminoid and other matters, permeated and tinged by chlorophyll, which is probably contained in a state of solution in the cell and not as a solid.

Physical and chemical properties of chlorophyll.—Considering the great importance of chlorophyll in relation to the process of assimilation in plants, it can hardly be a matter for surprise that it should very frequently have been examined. The literature of chlorophyll is very extensive, and comprises memoirs by physicists, chemists, and physiologists, some of them men of great eminence in their respective branches of science. Nevertheless, our knowledge of its properties, physical and chemical, is very scanty. The imperfect state of our knowledge of the subject is due to several causes. In the first place the quantity of chlorophyll contained in an extract of leaves, though the latter may be intensely coloured, is extremely small; secondly, chlorophyll is associated in the plant with large quantities of other substances, colouring matters, resins, fats, &c., which accompany it on extraction with ordinary solvents, and from which it cannot easily be separated; thirdly, it is a substance which is very apt to undergo change, so that during any process of purification to which it may be submitted, it will almost certainly be more or less altered; fourthly, chlorophyll, like most substances which play an important part in the vegetable or animal economy, is certainly amorphous, and the freedom from impurity of any specimen must therefore always be more or less doubtful. Some observers have described bodies which they have held to be crystallised chlorophyll, but the writer is of opinion that these were in all cases products of decomposition derived from chlorophyll. Chlorophyll contains nitrogen in addition to carbon, hydrogen and oxygen, but the percentage is certainly not large. It has been supposed to contain iron like the hæmoglobin of blood; after incineration a minute quantity of ferric oxide is indeed always found in the ash, but whether this is derived from chlorophyll, or from some substance or substances accompanying it, is uncertain. The ash also contains calcium and magnesium phosphates, but of these again it cannot with certainty be said that they are constituents of chlorophyll itself. Chlorophyll may be described as a neutral body, like indigo, having the properties neither of an acid nor a base; in constitution it may resemble the fats or the lecithins, as suggested by Hoppe-Seyler. Though not itself a glucoside, it is always found associated with a body having the characteristics peculiar to that class, as was first pointed out by the writer.

Chlorophyll is insoluble in water, but soluble in alcohol, ether, carbon disulphide and ethereal oils.

These solutions show a lively green colour of great intensity, accompanied by a marked red fluorescence. The solutions show an absorption spectrum which is quite characteristic, and must therefore be shortly described. A solution of chlorophyll made by extracting fresh green leaves with alcohol or ether is found, when very dark, to absorb nearly the whole spectrum, only a narrow strip of light at the extreme red end being visible. When the solution is made paler by the addition of more solvent, the green of the spectrum begins to appear, a faint absorption band showing itself about the middle. On still further diluting, other bands make their appearance in succession. When an average depth of colour is reached the following absorption bands are seen:—A very dark band beginning close to the line B and extending over C, followed by a second band between C and D which is much lighter, after which comes a third still paler one beyond D and close to the latter, lastly, a fourth band is seen partly on E which is usually the faintest of all, but is sometimes as dark as, and even darker than the third (see Fig. i.). Total obscuration begins about the line F. The four bands just described are usually marked with the numerals I.-IV. in accordance with the notation employed by Ångström, and are seen so constantly and invariably, when proper precautions are taken to have a solution of unchanged chlorophyll of average strength, as to constitute a certain test for chlorophyll, which may accordingly be defined as the substance which in solution shows this particular absorption spectrum. It should be mentioned that there is a considerable amount of obscuration throughout the whole spectrum of chlorophyll solutions, excepting only at the extreme red, so that the parts usually represented as white are in reality more or less darkened, and also that the bands, with the exception of band I., are not so sharply defined as the ordinary representations would lead one to suppose in consequence of the edges gradually shading off. Opinions differ as to whether the same absorption spectrum is seen when a green leaf is placed before the slit of a spectroscope, some observers maintaining that only band I. is discernible, while others say that all four bands can be made out, the only difference being that the bands are all shifted towards the red end, from which it has been inferred that in the plant chlorophyll exists in a state of solution, the solvent having a density greater than that of alcohol or ether. Returning to the solution of chlorophyll showing the spectrum just described, let us now see what takes place on further dilution. A beam of sunlight having been thrown on the slit of the spectroscope the solution is to be considerably diluted until it becomes quite pale. It will then be found that band I. having become narrower and paler has left the line C altogether and taken its place near B; band II. has become much narrower and paler, but remained in the same place, while bands III. and IV. have entirely disappeared. At the other end of the spectrum, however, two pale, ill-defined bands have made their appearance, one being situated between F and G, the other on G (see Fig. ii.). These bands are numbered V. and VI. Whether they belong to chlorophyll itself or to some other colouring matter accompanying it is uncertain, no one having as yet succeeded in obtaining a solution of chlorophyll in which they are not seen, provided the solution is sufficiently dilute and is observed in sun-light. The writer is of opinion that the two bands belong to a yellow colouring matter (xanthophyll?) always accompanying chlorophyll, from which the latter cannot be separated. It is certain that all leaves contain a colouring matter, the chrysophyll of Hartsen (Bougarel's erythrophyll), which may be obtained in lustrous, orange-coloured crystals, and gives yellow solutions, showing two distinct absorption bands at the blue end—not exactly in the same position as those just referred to—but no trace of any band in the other parts of the spectrum; the bands V. and VI. may belong to a nearly allied substance.

The absorption bands of chlorophyll solutions were first described by Sir D. Brewster, who was also the first to observe the red fluorescence of these solutions. The bands were next examined by Stokes and Ångström, by the latter of whom they were also correctly figured. Many other observers have worked on the same field; among these the following may be named: Askenasy, Gerland and Rawenhoff, Hagenbach, Harting, Kraus, L. Liebermann, Lommel, A. Meyer, Micheli, Morot, Pringsheim, Russell and Lapraik, Sacchse, Simmler, Sorby and Wiesner. The memoirs of Hagenbach, Kraus, Lommel, Pringsheim, Russell and Sorby on the subject are especially worthy of study. It should be mentioned that some of the absorption spectra figured in memoirs on chlorophyll really belong to derivatives of the latter. Whenever in such figures band IV. appears rather dark and is followed by another dark band nearer the blue end, we may conclude that the observer has worked with a specimen of chlorophyll that has undergone some change.

Products of decomposition of chlorophyll.—A solution of chlorophyll inclosed in a sealed tube and kept in the dark retains its colour for any length of time, but in an open vessel, especially when exposed to light, the colour disappears rapidly, only a faint yellow tinge remaining; what is formed during this change, which is doubtless due to oxidation, is not known.

By the action of acids chlorophyll undergoes a marked change, which no one who has worked with the substance can have failed to observe. When to an alcoholic solution of chlorophyll a small quantity of sulphuric or hydrochloric acid is added, the colour of the solution changes at once from a bright green to a dull yellowish-green or olive. Examined in the usual manner the spectrum will be found entirely altered; bands I. and II. have become more distinct from the clearing up of the space between the two, band III. appears much paler, and band IV. much darker, than before. After the solution has stood for some time band IV. will be found to have greatly increased in intensity, while another dark band has made its appearance near the line F just in front of the part where total obscuration begins. This is what has, not very appropriately, been called the absorption spectrum of *acid chlorophyll*, and is due to the formation of products derived from chlorophyll by a process the nature of

**which is not understood. That this process is not such a one as might admit of explanation by supposing chlorophyll to have the constitution of a salt, its acid constituent being expelled by the addition of a stronger acid, is proved by the fact that if alcoholic potash or soda be added in excess to a solution of chlorophyll which has been acted on by acids, the original bright green colour is not restored. To those conversant with the decomposition of complex organic substances, another explanation may suggest itself, viz. that the change is due to hydrolysis in presence of an acid, accompanied perhaps by a splitting up of the same kind as that which glucosides undergo when acted on by acids or ferments. Russell and Lapraik are of opinion that the change is a molecular, not a chemical one. Weak acids produce the same change as strong ones, but only after some time. On the addition of a comparatively large quantity of acetic acid to an alcoholic solution of chlorophyll, no change of colour is perceived at first, nor is the spectrum in any way altered, but on standing the colour slowly passes over to yellowish-green, and the same bands make their appearance as when a strong acid is employed. The same change frequently takes place when a solution of chlorophyll is left to stand in a loosely-stoppered bottle kept in the dark; in this case the effect is probably due to the presence of some substance, an ethereal oil for instance, which by oxidation yields an acid of some kind. Some leaves, such as those of the vine and virginian creeper, naturally contain much free acid which, on extraction of the leaves with alcohol, accompanies the chlorophyll and changes it after a short time.

In order to obtain the products derived from chlorophyll by the action of acids, fresh green leaves are extracted with boiling spirits of wine; the liquor after straining is allowed to stand, so that a portion of the fatty matter contained in it may be deposited, after which it is filtered and a current of hydrochloric acid gas is passed through it. By the action of the acid a dark brownish-green flocculent precipitate is formed, which after standing is filtered off and washed with alcohol. This precipitate contains two peculiar colouring matters, which Fremy named *phyllocyanin* and *phylloxanthin*, along with impurities of a fatty nature. The two colouring matters are separated by Fremy's method; the mixture is dissolved in ether, and the solution is shaken up with about a quarter its volume of concentrated ClH, whereupon it separates into two layers, an upper yellowish-green one containing phylloxanthin, and a lower bright-blue one containing phyllocyanin.

The phylloxanthin of the upper stratum is largely contaminated by fatty matter, from which it cannot easily be separated, but the phyllocyanin from the lower stratum can be purified and is obtained in microscopic crystals, which are generally opaque, but when very thin appear olive-coloured by transmitted light. The general properties of phyllocyanin have been described by the writer, but a few only of these can here be mentioned. Phyllocyanin is a body entirely *sui generis*, resembling no other natural colouring matter. It is insoluble in water and ligroïn, but soluble in alcohol, ether, acetic acid, chloroform, benzene, and carbon disulphide. The solutions show an absorption spectrum with five bands (see Fig. iii.). It dissolves in concentrated ClH and SH_2O_4 giving solutions of a bright blue colour, and is reprecipitated unchanged by water. It dissolves in alkaline lyes, but is entirely changed by the action of the alkali. Its most interesting property is that of yielding by the combined action of acids, chiefly organic acids, and metallic oxides, such as cupric, ferrous and zinc oxides, compounds, the solutions of which are bright green and closely resemble solutions of chlorophyll not only in colour but in other respects also.

Phyllocyanin is remarkable for its great stability; its solutions remain for a long time unchanged when exposed to light and air, whereas solutions of chlorophyll are rapidly bleached under the same circumstances. Phyllocyanin yields with alkalis and reducing agents products which show absorption spectra of great variety and beauty (see Figs. v. and vi.). Phylloxanthin resembles phyllocyanin in many of its properties, but is a less interesting substance. Its absorption spectrum shows only four bands (see Fig. iv.). It will be seen that when the two substances are present together in solution, the bands of phylloxanthin will be concealed by those of phyllocyanin.

On reading some of the older memoirs on chlorophyll, such as those of Berzelius, Mulder, and Fremy, it will be evident that the authors worked not with chlorophyll itself, but with products due to the action of acids on the latter. It is probable that the *chlorophyllan* of Hoppe-Seyler and the *hypochlorin* of Pringsheim are products belonging to the same class as phyllocyanin and phylloxanthin. According to Tschirch chlorophyllan is the first product of the action of acids on chlorophyll, and splits up into phyllocyanin and phylloxanthin when the action of acid is prolonged. This short account may serve to show that our knowledge of the derivatives of chlorophyll is still very defective.

Chlorophyll in relation to plant life.—There can be no doubt that the presence of chlorophyll is necessary during the process of assimilation by plants, but what part it plays in the process is unknown. It was at first supposed, considering how powerfully the more refrangible end of the spectrum is absorbed by solutions of chlorophyll, that it was especially the blue rays that effected the decomposition of CO_2 and H_2O within the cells. This idea was soon abandoned in favour of another theory, according to which it is the red rays that are more active than the others in promoting assimilation, they being also strongly absorbed by chlorophyll. The latest investigations make it probable that the yellow rays, which are the least absorbed of any, produce a more abundant evolution of O, and consequently a greater amount of decomposition of CO_2 and H_2O than either the red or blue rays. Pringsheim is of opinion that chlorophyll acts simply as a screen which absorbing the less refrangible rays, moderates the energetic heating and oxidising action of the latter during the process of assimilation. All that can be positively asserted with regard to this part of the subject is that the colour, *i.e.* the absorptive power of chlorophyll has something to do with its mode of action.

It has been thought, and we often find it stated in books, that chlorophyll has itself the power of absorbing CO_2 and evolving O; attempts have even been made to prove that this takes place in ordinary solutions of chlorophyll. This is, however, erroneous; it is certain that the complex which physiologists call the chlorophyll corpuscle, or simply chlorophyll, has the power of decomposing CO_2 and H_2O with evolution of O, but that any such power resides in the colouring matter when dissociated from the other constituents of the complex must be incorrect, since it is opposed to all that we know of the chemical properties of organic substances.

List of the most important memoirs and works on chlorophyll:—

Ångström, *Ueb. d. grüne Farbe d. Pflanzen*, *P.* 93, 475; Askenasy, *Bot. Ztg.*, 1867, 225; Berzelius, *Untersuchung d. Blattgrüns*, *A.* 27, 296; Brewster, *On the Colours of Natural Bodies*, *T. E.* 12, 538; Chautard, *Examen spectroscopique de la chlorophylle*, *C. R.* 76, 103, 570, 1031, 1066, 1273; Filhol, *C. R.* 61, 371; 66, 1218; 79, 612; Fremy, *Sur la matière colorante verte des feuilles*, *C. R.* 50, 405; 61, 188; Gautier, *Sur la chlorophylle*, *C. R.* 89, 862; Gerland and Rawenhoff, *Recherches sur la chlorophylle*, *Ar. N.* 6, 97; Hagenbach, *Untersuchungen üb. d. optischen Eigenschaften d. Blattgrüns*, *P.* 141, 245; Harting, *P.* 96, 543; Hansen, '*Der Chlorophyllfarbstoff*,' *Arb. d. bot. Inst. in Würzburg*, 3, 1; Hartsen, *C. C.* 1872, 524, 1875, 618; Hoppe-Seyler, *Ueber d. Chlorophyll d. Pflanzen*, *H.* 3, 1879, 339; 4, 1880, 193, 5, 1881, 75; Kraus, *Zur Kenntniss d. Chlorophyllfarbstoffe*, Stuttgart, 1872; Kromeyer, *Zerlegung des Chlorophylls in einem blauen und einem gelben Farbstoff*, *Ar. Ph.* 155, 164; L. Liebermann, *Sitz. W.* 72, 599; Lommel, *Ueb. d. " iii. " " " phyllocyanin.
" iv. " " " phylloxanthin.
" v. " " " a phyllocyanin derivative.
" vi. " " " ethyl compound of the preceding.

CHLORO-PICOLINE *v.* CHLORO-METHYL-PYRIDINE.

CHLORO-PICOLINIC ACID *v.* CHLORO-PYRIDINE CARBOXYLIC ACID.

CHLOROPICRIN *v.* TRI-CHLORO-NITRO-METHANE.

CHLOROPLATINATES *v.* PLATINATES under PLATINUM.

CHLORO-PROPANE *v.* PROPYL CHLORIDE.

ωα-Di-chloro-propane $C_3H_6Cl_2$ *i.e.* $CH_3.CHCl.CH_2Cl$. *Propylene chloride.* Mol. w. 113. (97° cor.). S.G. ^{0} 1·584; ^{14} 1·155 (F. a. S.); ^{14} 1·166 (Linnemann, *A.* 161, 62).

Formation.—1. From chlorine and propylene (Cahours, *A.* 76, 283; Reynolds, *A.* 77, 124).—2. From chloro-iodo-propane and Cl (Friedel a. Silva, *C. R.* 76, 1596).—3. From propane and Cl (Schorlemmer, *Pr.* 17, 372; *A.* 150, 214).—4. Together with $CH_3.CCl_2.CH_3$, by chlorinating $CH_3.CHCl.CH_3$ in sunshine (Friedel a. Silva, *Bl.* [2] 16, 3).—5. From isopropyl chloride and ICl (Friedel a. Silva, *C. R.* 73, 1380).—6. From allyl chloride and conc. HCl at 100° (Reboul, *A. Ch.* [5] 14, 453).

Reactions.—1. Alcoholic KOH gives α-chloro-propylene $CH_3.CCl:CH_2$ (Friedel a. Silva, *A. Ch.* [4] 16, 349).—2. *Water* (20 vols.) at 220° gives propionic aldehyde and acetone. Water and PbO at 150° give propylene glycol (Eltekoff, *B.* 6, 558).—3. Conc. HI at 150° gives isopropyl chloride.

ωω-Di-chloro-propane $CH_3.CH_2.CHCl_2$. *Propylidene chloride.* (86°). S.G. ^{10} 1·143. Formed, together with chloro-propylene $CH_3.CH:CHCl$, by the action of PCl_5 on propionic aldehyde (Reboul, *A. Ch.* [5] 14, 458). Alcoholic KOH gives $CH_3.CH:CHCl$ (34°).

αα-Di-chloro-propane $CH_3.CCl_2.CH_3$. *Chloracetol. Methylchloracetol.* (70°). S.G. $\frac{15}{15}$ 1·0966; $\frac{25}{25}$ 1·0848 (Perkin, *C. J.* 45, 529); ^{16} 1·827 (Linnemann, *A.* 161, 67). H.F.p. 42080. H.F.v. 40340 (*Th.*).

Formation.—1. From acetone and PCl_5 (Friedel, *A.* 112, 236).—2. From isopropyl chloride and Cl (Friedel a. Silva, *Z.* 1871, 489).—3. From allylene and fuming HCl in the cold (Reboul, *A. Ch.* [5] 14, 453).

Reactions.—1. Alcoholic KOH forms α-chloro-propylene $CH_3.CCl:CH_2$ (24°).—2. AgOBz gives $(CH_3)_2C(OBz)_2$.—3. *Water* (8 vols.) at 170° gives acetone (Oppenheim, *B.* 2, 213).

ωβ-Di-chloro-propane $CH_2Cl.CH_2.CH_2Cl$. *Trimethylene chloride.* (119°). S.G. ^{15} 1·201 (R.); $\frac{17\cdot6}{4}$ 1·1896 (F.). From the corresponding dibromide and $HgCl_2$ at 180° (Reboul, *A. Ch.* [5] 14, 453). Formed also from trimethylene glycol $CH_2OH.CH_2.CH_2OH$ and HCl (Freund, *M.* 2, 638). Alcoholic KOH gives allyl chloride.

ωαβ-Tri-chloro-propane $C_3H_5Cl_3$ *i.e.* $CH_2Cl.CHCl.CH_2Cl$. *Trichlorhydrin. Glyceryl chloride. Allyl trichloride.* (158°). S.G. $\frac{15}{15}$ 1·3984; $\frac{25}{25}$ 1·3878 (Perkin, *C. J.* 45, 532); ^{0} 1·41 (O.). M.M. 7·897 at 21·6°.

Formation.—1. From glycerin dichlorhydrin (di-chloro-propyl alcohol) and PCl_5 (Berthelot a. De Luca, *A. Ch.* [3] 48, 304; 52, 433; Fittig, *A.* 135, 359).—2. By passing Cl into allyl iodide under water (Oppenheim, *Bl.* [2] 2, 97).—3. One of the products of chlorination of propylene chloride (Belohoubek, *B.* 9, 924), or of propane (?) (Berthelot, *A.* 155, 105).—4. From propylene chloride and ICl at 160° (Friedel a. Silva, *Z.* 1871, 683).

Reactions.—1. *Water* (20 vols.) by heating at 160° for 24 hours forms glycerin.—2. KOH gives $CH_2:CCl.CH_2Cl$ (101°) and a little $CHCl:CH.CH_2Cl$.—3. Alcoholic KSH gives $C_3H_5(SH)_3$.—4. Alcoholic NH_3 forms $(C_3H_4Cl)_2NH$.—5. Al_2I_6 gives allyl iodide (Gustavson, *C. C.* 1877, 19).

ωωω-Tri-chloro-propane $CH_3.CH_2.CCl_3$ (145°–150°). From Pr_2S and dry Cl in daylight (Spring a. Lecrenier, *Bl.* [2] 48, 623). Ag_2O converts it into propionic acid.

ωωα-Tri-chloro-propane $CH_3.CHCl.CHCl_2$. *α-Chloro-propylidene chloride.* (140°). S.G. ^{9} 1·402; ^{25} 1·372. Formed by chlorination of propylene or propylidene chloride in sunshine. Also, together with the preceding, by heating propylene chloride with ICl at 160° (Friedel a. Silva, *C. R.* 74, 805). Formed by union of $CH_3.CCl:CH_2$ with Cl (Berthelot, *A.* 155, 105).

ωαα-Tri-chloro-propane $CH_3.CCl_2.CH_2Cl$. (123°). S.G. ^{0} 1·350; ^{25} 1·318.

Formation.—1. From $CH_3.CCl_2.CH_3$ by Cl in sunshine, or by ICl (F. a. S.).—2. From propylene chloride and Cl (Belohoubek, *B.* 9, 924). 3. From chloro-acetone and PCl_5.—4. From $CH_3.CCl:CH_2$ and Cl at 0° in sunshine.

Reactions.—1. *Water* at high temperatures forms $CH_3.CO.CHO$ (?).—2. Alcoholic KOH gives two di-chloro-propylenes (75°) and (94°) (Friedel a. Silva, *C. R.* 74, 806).

Tri-chloro-propane $CH_2Cl.CH_2.CHCl_2$. *β-Chloro-propylidene chloride.* (147°). S.G. ^{15} 1·362. V.D. 4·95. Formed by the action of PCl_5 on β-chloro-propionic aldehyde or on acrolein (Geuther, *Z.* 1865, 29; van Romburgh, *Bl.* [2] 37, 98). Alcoholic KOH gives di-chloro-propylene $CH_2:CH.CHCl_2$.

Tetra-chloro-propane $CH_3.CCl_2.CHCl_2$. (153°). S.G. ^{13} 1·47. From di-chloro-acetone and PCl_5 (Borsche a. Fittig, *A.* 133, 114). Also from allylene dichloride (Pinner, *A.* 179, 47). Apparently the same body is formed as a by-product in the preparation of tri-chloro-butyric aldehyde by chlorinating aldehyde (Pinner, *B.* 10, 1057). Alcoholic KOH gives $C_3H_3Cl_3$ (115°).

Tetra-chloro-propane $C_3H_4Cl_4$ *i.e.* $CH_2Cl.CH_2.CH_3$? [178°]. (203°). From propane and Cl in sunshine (Schorlemmer, *Pr.* 18, 29). Stellate groups of needles (from alcohol). Smells like camphor.

Tetra-chloro-propane $CH_2Cl.CCl_2.CH_2Cl$. *Iso-allylene tetrachloride.* (164°). S.G. ^{17} 1·496. From $CH_2Cl.CCl:CH_2$ (95°) and Cl or HOCl (Fittig a. Pfeffer, *A.* 135, 360; Henry, *C. R.* 94, 1428). Also from $CH_3.CCl:CH_2$ and Cl (Berthelot, *A.* 155, 105). Alcoholic KOH gives $C_3H_3Cl_3$. Alcoholic NH_3 gives $(C_3H_3Cl_2)_2NH$. Sodium gives allylene.

Tetra-chloro-propane $C_3H_4Cl_4$ *i.e.* $CH_3.CHCl.CCl_3$. [145°]. (c. 185°). From isopropyl iodide and Cl. Resembles camphor (B.).

Tetra-chloro-propane $C_3H_4Cl_4$. (c. 198°). S.G. 1·55. From propylene chloride and Cl (Cahours, *A.* 76, 283). Probably identical with the preceding or, possibly, with the following.

Tetra-chloro-propane $CH_2Cl.CHCl.CHCl_2$. *Tetra-chloro-glycide. Allylidene tetrachloride.* (180°). S.G. $\frac{15}{4}$ 1·521. V.D. 6·8. From $CH_2.CCl:CH_2Cl$ and Cl (Hartenstein, *J. pr.* [2] 7, 318). From $CH_2:CH.CHCl_2$ and Cl (van Romburgh, *Bl.* [2] 36, 553).

Penta-chloro-propane $C_3H_3Cl_5$ *i.e.* $CH_2Cl.CCl_2.CHCl_2$. (194°). From di-chloro-acetone and PCl_5 (Borsche a. Fittig, *A.* 133, 116). Alcoholic KOH gives $C_3H_2Cl_4$ (165°).

Penta-chloro-propane $C_3H_3Cl_5$ *i.e.* $CH_3.CCl_2.CCl_3$? From $CH_3.CCl_2.CHCl_2$ and Cl (B. a. F.). Prisms.

Penta-chloro-propane $C_3H_3Cl_5$. (c. 223°). From propylene chloride and Cl (Cahours, *A.* 76, 283).

Hexa-chloro-propane $C_3H_2Cl_6$ *i.e.* $CCl_3.CH_2.CCl_3$? (250°). Formed by chlorinating propane in the brightest sunshine (Schorlemmer, *Pr.* 18, 29). Liquid, smelling like camphor.

Hexa-chloro-propane $C_3H_2Cl_6$ *i.e.* $CCl_3.CHCl.CHCl_2$? (c. 248°). S.G. 1·63. From propylene chloride and Cl (Cahours, *A.* 76, 283).

Hepta-chloro-propane C_3HCl_7. (260°). S.G. 1·78. From propylene chloride and Cl (Cahours).

Per-chloro-propane C_3Cl_8. [160°]. (269°). From $CH_2Cl.CHCl.CH_2Cl$ and ICl_3 at 200°. Formed also, together with CCl_4, by heating isobutane with ICl_3 at 240° (Krafft a. Merz, *B.* 8, 1045); and, together with C_2Cl_6 and CCl_4 by the action of ICl_3 on isobutyric acid (Krafft, *B.* 9, 1085). Crystalline mass; v. e. sol. alcohol, ether and ligroin. At 250° it splits up into C_2Cl_4 and CCl_4.

CHLORO-PROPANE SULPHONIC ACID $C_3H_6Cl.SO_3H$. From the product of the action of ICl_3 on propane sulphonic acid at 160° the salts $(C_3H_6ClSO_3)_2Ba(C_3H_7SO_3)_2Ba$ aq and $(C_3H_6ClSO_3)_2Ba3(C_3H_7SO_3)_2Ba$ may be isolated (Spring a. Winssinger, *B.* 16, 328).

α-CHLORO-PROPIONIC ACID $C_3H_5ClO_2$ *i.e.* $CH_3.CHCl.CO_2H$. Mol. w. 108½. (186°). S.G. ^{0} 1·28.

Preparation.—Calcic lactate (17 g.) is shaken with PCl_5 (40 g.) and distilled from a bath of H_2SO_4. The distillate is mixed in the cold with the requisite quantity of cold water. The yield is 60 per cent. (J. M. Lovén, *J. pr.* [2] 29, 366; *cf.* Wurtz, *A.* 107, 192; Ulrich, *A.* 109, 271; Lippmann, *A.* 129, 81; Buchanan, *Z.* [2] 4, 523; Brühl, *B.* 9, 35; Mazzara, *G.* 12, 261).

Properties.—Liquid, miscible with water; blisters the skin.

Reactions.—1. *Zinc* and HCl convert it into propionic acid.—2. The solutions of the Ba and Ag salts change to lactate on boiling.—3. With conc. solution of KHS (2 mols.) it gives thiolactate and thiodilactylate of potassium.

Salts.—AgA'.—BaA'_2.

Methyl ether MeA'. (132½°). S.G. ^{4} 1·075. μ_D 1·423 (Kahlbaum, *B.* 12, 344).

Ethyl ether EtA'. (147°). S.G. $\frac{20}{4}$ 1·0869. μ_β 1·4237. R_∞ 51·12 (Brühl, *A.* 203, 24). *Reactions.*—1. When heated with *thiurea* 5 hours at 100° it gives the hydrochloride of lactylthio-urea:

$CS\langle{NH.C_2H_4 \atop NH.CO}$.—2. With *potassium sulphocyanide* 5 hours at 150° it gives $CH_3.CH(SCN).CO_2Et$ (Freytag, *J. pr.* 128, 380). 3. NaOEt gives $CH_3.CH(OEt).CO_2Et$.

Amide $CH_3.CHCl.CONH_2$. [80°]. Scales; v. sol. water (Beckurts a. Otto, *B.* 9, 1592).

Chloride $CH_3.CHCl.COCl$. (110°). V.D. 4·38. S.G. ^{15} 1·289 (Henry, *C. R.* 100, 114).

Nitrile $CH_3.CHCl.CN$. (122°). Pungent liquid.

β-Chloro-propionic acid $CH_2Cl.CH_2.CO_2H$. [41°]. (B. a. O.); [38°] (H.). (204°).

Formation.—1. By heating hydracrylic acid with fuming HCl at 120° (Beckurts a. Otto, *B.* 18, 226).—2. From its chloride, which is formed by the union of ethylene with $COCl_2$ (Lippmann, *A.* 129, 81; Henry, *C. R.* 100, 114).—3. From acrylic acid and HCl (Linnemann, *A.* 163, 95).—4. From β-iodo-propionic acid and chlorine-water (Richter, *Z.* 1868, 451).

Properties.—White plates; v. e. sol. water and alcohol. Does not blister the skin.

Methyl ether MeA'. (156°).

Ethyl ether EtA'. (163°). V.D. 4·94. S.G. ^{0} 1·116.

Chloro-ethyl ether $CH_2Cl.CH_2A'$. (c. 218°). S.G. ^{0} 1·282. From the acid and $CH_2OH.CH_2Cl$ (H.).

Chloride $CH_2Cl.CH_2.COCl$. (144°). V.D. 4·42. S.G. ^{13} 1·331.

αα-Di-chloro-propionic acid $CH_3.CCl_2.CO_2H$. (c. 188°).

Formation.—1. From pyruvic acid and PCl_5 (Klimenko, *B.* 3, 465; 5, 477; Beckurts a. Otto, *B.* 11, 386).—2. The nitrile is formed by chlorinating propionitrile (Otto, *A.* 132, 181; *B.* 9, 1877).

Properties.—Liquid; v. sol. water; insol. conc. HCl. Solidified by cold. Converted by zinc and HCl into propionic acid. Water at 140° gives pyruvic acid. Boiling alcoholic KOH gives α-chloro-acrylic acid. Reduced silver forms $CO_2H.CMe{:}CMe.CO_2H$ and CO_2H; $CMeCl.CMeCl.CO_2H$.

Salts. — NH_4A'. — KA' 6aq. — BaA'_2 aq. — CaA'_2 aq.—CaA'_2 3aq.—ZnA'_2 aq: easily soluble flat needles.—AgA'.—On heating with water it decomposes into pyruvic acid, dichloropropionic acid, and AgCl. On heating the dry salt it yields pyruvic-dichloropropionic anhydride

${CH_3.CO.CO \atop CH_3.CCl_2.CO}\rangle O$ and AgCl (Beckurts a. Otto, *B.* 18, 227).

Methyl ether MeA'. (144°).

Ethyl ether EtA'. (157°) (B. a. O.); (160°) (K.). S.G. ^{0} 1·249.

Isobutyl ether CH_2PrA'. (184°).

Allyl ether C_3H_5A'. (177°).

Chloride $CH_3.CCl_2.COCl$ (c. 110°).

Anhydride $(CH_3.CCl_2.CO)_2O$. (191°).

Amide $CH_3.CCl_2.CONH_2$. [116°]. Monoclinic laminæ (Haushofer, *Z. K.* 7, 267).—$(CH_3.CCl_2.CONH)_2Hg$ aq: needles.

Nitrile $CH_3.CCl_2.CN$. (105°). S.G. ^{15} 1·431.

Paranitrile $(CH_3CCl_2)_3C_3N_3$(?). [74°]. S. (alcohol) 14 at 20°. Chlorine acting upon propionitrile forms a liquid di-chloro-propionitrile (104°–107°) and a solid isomeride [74°]; the formation of the latter is promoted by a low temperature. Both give the same di-chloro-propionic acid on saponification, hence the solid form is probably a polymeride of the liquid. The liquid form sometimes changes spontaneously into the solid form (Otto a. Voigt, *J. pr.* [2] 36, 79). *Reactions of the paranitrile.*—1. H_2SO_4 (1 vol.) mixed with water (1 vol.) at 180° gives α-di-chloropropionic acid.—2. Alcoholic NH_3 gives di-chloro-propionamide. — 3. *Zinc and acetic acid* reduce it to $(C_2H_5)_3C_3N_3$ (195°).—4. *Zinc* acting on a solution in dilute alcohol forms a **base** $C_9H_{15}N_3$, [111°], (c. 273°), crystallising from petroleum ether in needles or plates, v. sol. ether and alcohol, v. sl. sol. water. It forms salts: B'HCl.—$B'_2H_2PtCl_6$.—$AgC_9H_{14}N_3$ ½aq.

αβ-Di-chloro-propionic acid $CH_2Cl.CHCl.CO_2H$. [50°]. (210°).

Formation.—1. From glyceric acid and HCl (Werigo, *B.* 12, 178; *cf.* *A.* 170, 163).—2. From di-chloro-propyl alcohol $CH_2Cl.CHCl.CH_2OH$ by oxidation (Henry, *B.* 7, 414; Werigo a. Melikoff, *B.* 10, 1500).—3. From α-chloro-acrylic acid and HCl at 180° (W. a. M.).—4. Formed from $CH_2(OH).CHCl.CO_2H$ and fuming HCl at 100° (Melikoff, *J. R.* 13, 163; *C. C.* 1881, 354).

Properties.—Small needles. Alcoholic KOH gives α-chloro-acrylic acid.—HO.PbA′.

Ethyl ether EtA′. (184°). S.G. $^{20}_{4}$ 1·2461. μ_{β} 1·4538. R_{∞} 59·75 (Brühl, *A.* 203, 25). Successive treatment with alcoholic KCy and KOH gives fumaric and inactive malic acids (Werigo a. Tanatar, *A.* 174, 367).

ββ-Di-chloro-propionic acid $CHCl_2.CH_2.CO_2H$. [56°]. From β-chloro-acrylic acid and aqueous HCl at 80° (Otto a. Fromme, *A.* 239, 268). Prisms, v. sol. alcohol, ether, benzene, chloroform, and water. Converted by alcoholic KOH into $CHCl{:}CH.CO_2H$.

Ether EtA′. (171°-175°).

Amide $CHCl_2.CH_2.CO.NH_2$. [140°]: needles.

Tri-chloro-propionic acid (?) $C_3H_3Cl_3O_2$ (?). [60°]. From per-chloro-succinic ether and conc. KOHAq (Malaguti, *A. Ch.* [3] 16, 67, 72, 82).—AgA′.

β-CHLORO-PROPIONIC ALDEHYDE C_3H_5ClO *i.e.* $CH_2Cl.CH_2.CHO$. *Acroleïn hydrochloride.* (c. 45°) at 10 mm. (130°-170°). Formed, together with the paraldehyde, by passing gaseous HCl into acroleïn (Geuther a. Cartmell, *A.* 112, 3; Krestownikoff, *J. R.* 11, 249; Grimaux a. Adam, *C. R.* 92, 300). Liquid. Reduces Fehling's solution. Rapidly changes to the solid paraldehyde. HNO_3 forms β-chloro-propionic acid.

β-Chloro-propionic paraldehyde $(C_3H_5ClO)_3$(?). [33·5°]. (170°-175°) at 15 mm. Formed by spontaneous polymerisation of the preceding, into which it is reconverted by distillation under ordinary pressure. Needles. Insol. water. It does not reduce Fehling's solution. Not acted upon by water or baryta at 100°, nor by AgOAc or $Pb(OAc)_2$ at 120°. Water at 120° gives HCl and metacroleïn. Distillation over solid KOH also forms some metacroleïn.

αβ-Di-chloro-propionic aldehyde $CH_2Cl.CHCl.CHO$. From acroleïn and Cl (Aronstein, *A. Suppl.* 3, 190). Oil. Its alcoholate $CH_2Cl.CHCl.CH(OH)(OEt)$ boils at 150°-155°.

β-CHLORO-PROPYL ALCOHOL C_3H_7ClO *i.e.* $CH_2Cl.CH_2.CH_2OH$. *Trimethylene chlorhydrin.* (161° cor.). S.G. ^{21} 1·132. S. 50. From trimethylene glycol $CH_2OH.CH_2.CH_2OH$ and HCl at 100° (Reboul, *A. Ch.* [5] 14, 491).

α-Chloro-isopropyl alcohol $CH_3.CH(OH).CH_2Cl$. *Propylene chlorhydrin.* (128°). S.G. [illegible] 1·130.

Formation.—1. From propylene glycol and HCl (Oser, *A. Suppl.* 1, 254) or S_2Cl_2 (Morley, *B.* 13, 1805).—2. From allyl chloride (1 pt.) and conc. H_2SO_4 (3 pts.) at 100°; the product being distilled with water (10 pts.) (Oppenheim, *A. Suppl.* 6, 367).—3. From propylene and HOCl (Markownikoff, *Z.* 1870, 423).

Properties.—Liquid, sol. water. May probably contain $CH_3.CHCl.CH_2OH$.

Reactions.—1. P_2O_5 gives allyl chloride and chloro-propylene (Henry, *Z.* 1871, 600).—2. The chlorhydrin obtained by the action of S_2Cl_2 upon propylene glycol gives chloro-acetone on oxidation with $K_2Cr_2O_7$ and H_2SO_4, or with HNO_3 (Morley a. Green, *B.* 18, 24; *C. J.* 47, 132). The chlorhydrin obtained from propylene and HOCl is oxidised (by chromic mixture) to chloro-acetone according to Markownikoff, or (by HNO_3) to α-chloro-propionic acid according to Henry (*B.* 7, 1649, 1790).—3. HNO_3 gives chloro-acetic acid (Henry, *Bl.* [2] 25, 389).—4. Heating with ZnO or PbO gives propionic aldehyde and acetone (Eltekoff, *J. R.* 10, 222).

Benzoyl derivative C_3H_6ClOBz. (269° cor.). S.G. ^{19} 1·172; ^{15} 1·149. From the alcohol and BzCl. Oil. Alkalis form propylene oxide. $ZnEt_2$ gives propylene ethyl phenyl ketate $C_5H_6{<}\substack{O\\O}{>}CEt.C_6H_5$ (Morley a. Green, *C. J.* 47, 134; *B.* 17, 3015).

Ethyl ether $CH_3.CH(OEt).CH_2Cl$. (118°). S.G. ^{0} ·984. From di-chloro-di-ethyl oxide and $ZnMe_2$ (Lieben, *A.* 146, 225; 178, 14).

αβ-Di-chloro-propyl alcohol $CH_2Cl.CHCl.CH_2OH$. *Dichloride of allyl alcohol.* (182°). S.G. ^{0} 1·380 (T.); $^{17·5}$ 1·355 (G.).

Formation.—1. From allyl alcohol and Cl (Tollens, *A.* 156, 164; Hübner a. Müller, *A.* 159, 168).—2. From allyl chloride and HOCl (v. Geyerfeldt, *A.* 154, 247; *B.* 6, 720; Henry, *B.* 3, 352; 7, 414).—3. Together with its isomeride, by passing dry HCl into glycerin (Fauconnier a. Sanson, *Bl.* [2] 48, 236). According to Markownikoff (*A.* 208, 349) passing HCl into a mixture of glycerin and aqueous HCl only produces $CH_2Cl.CH(OH).CH_2Cl$ (*cf.* Tollens, *Z.* 1869, 174).

Properties.—Viscid oil, sl. sol. water, sol. alcohol. Aqueous NaOH gives epichlorhydrin (119°). HNO_3 gives αβ-di-chloro-propionic acid.

Di-chloro-isopropyl alcohol $C_3H_6Cl_2O$ *i.e.* $CH_2Cl.CH(OH).CH_2Cl$. *Glycerin dichlorhydrin.* Mol. w. 129. (176° i.V.). S.G. ^{0} 1·383; ^{19} 1·367 (Markownikoff, *A.* 208, 349). S. 11 at 19°.

Formation.—1. From glycerin and HCl (Berthelot, *A.* 92, 302; Hübner a. C. Müller, *Z.* [2] 6, 344; Watt, *B.* 5, 257).—2. From glycerin and S_2Cl_2 (Carius, *A.* 122, 73; Claus, *A.* 168, 42).—3. From epichlorhydrin and fuming HCl (Reboul, *A. Suppl.* 1, 225).—4. Together with its isomeride, by the union of HOCl with allyl chloride (Henry, *B.* 3, 352).

Reactions.—1. *Chromic acid mixture* oxidises it to s-di-chloro-acetone [43°] and chloro-acetic acid.—2. *Sodium amalgam* converts it into isopropyl alcohol (Buff, *A. Suppl.* 5, 250).—3. *Sodium* added to its ethereal solution forms allyl alcohol (H. a. M.; Tornöe, *B.* 21, 1282).—4. Alcoholic (4 p.c.) NH_3 (2½ mols.) forms amorphous 'chlorhydrinimide' $C_{12}H_{27}N_3Cl_2O_4$. Weaker alcoholic NH_3 (1 p.c.) forms hydrochlorides of 'di-amido-hydrin' $C_3H_{10}N_2O$, and of 'glycidamine' C_3H_7NO (Claus, *A.* 168, 29; *B.* 8, 244).—5. *Aniline* forms C_3H_6ONPh.—6. Solid NaOH gives epichlorhydrin C_3H_5ClO.—7. Br at 100° gives di-chloro-di-bromo-acetone $CBr_2Cl.CO.CH_2Cl$ and chloro-tri-bromo-acetone (Grimaux a. Adam, *Bl.* [2] 32, 18).—8. P_2O_5 acts vigorously, forming di-chloro-propylene.

Formyl derivative $CH_2Cl.CH(OCHO).CH_2Cl$. (c. 152°) at 22 mm. Formed by heating the alcohol with nitro-methane at 220° (Pfungst, *J. pr.* [2] 34, 28). The nitro-methane may perhaps first form hydroxylamine and formic acid: $CH_3NO_2 + H_2O = CH_2O_2 + NH_3O$; but no hydroxylamine could be found.

Acetyl derivative $CH_2Cl.CH(OAc).CH_2Cl$. (204°) (B. a. L.; T.); (195°) (H.); (c. 142° at 25 mm.) (P.). S.G. ^{11} 1·283 (T.); ^{2} 1·274 (H.).

Formation.—1. From glycerin and AcCl.—2. By passing HCl at 100° into a mixture of glycerin and HOAc (Berthelot a. De Luca, *A.Ch.* [3] 52, 459).—2. From $CH_2Cl.CH(OH).CH_2Cl$ and AcCl (Henry, *B.* 4, 704).—3. From epichlorhydrin and AcCl (Truchot, *A.* 138, 297).—4. From the formyl derivative and AgOAc (Pfungst, *J. pr.* [2] 34, 28).

Butyryl derivative $(CH_2Cl)_2CH.O.CO.C_3H_7$. (227°). S.G. ^{11} 1·194 (T.).

Isovaleryl derivative $(CH_2Cl)_2.CH.O.CO.C_4H_9$. (245°) at 737 mm. S.G. ^{11} 1·149 (Truchot, *A.* 138, 297).

Benzoyl derivative $(CH_2Cl)_2CH.OBz$. (222°) at 40 mm. S.G. ^{2} 1·441. From epichlorhydrin and BzCl at 180° (T.). Also from the formyl derivative and BzCl (P.).

Tri-chloro-isopropyl alcohol $CCl_3.CH(OH).CH_3$. [49°]. (150°–160°). From chloral by successive treatment with $ZnMe_2$ and water (Garzarolli-Thurnlackh, *A.* 210, 77). Small deliquescent needles (from ether). May be sublimed. Smells like camphor.

TRI-CHLORO-PROPYLAMINE $C_3H_4Cl_3.NH_2$. Formed by the action of Sn and HCl on dinitro-allylene-dichloride $C_3H_4Cl_2(NO_2)_2$ (Pinner, *A.* 179, 55). Oil; may be distilled.

β-CHLORO-α-PROPYL-CINNAMIC ACID $C_6H_5.CCl:C(C_3H_7).CO_2H$. [121°]. From its ether, which is formed by treating propyl-benzoyl-acetic ether with PCl_5 (W. H. Perkin, jun., *C. J.* 49, 163). Triclinic prisms; $a:b:c = \cdot797:1:\cdot740$; $\alpha = 122°33'$; $\beta = 106°21'$; $\gamma = 69°25'$ (Haushofer). May be sublimed. V. sol. alcohol, ether, benzene, chloroform, and HOAc; m. sol. ligroin.

Ethyl ether EtA'. (248°) at 300 mm. Oil.

β-CHLORO-PROPYLENE $CH_2:CH.CH_2Cl$ *v.* ALLYL CHLORIDE.

ω-Chloro-propylene $CHCl:CH.CH_3$. *Propenyl chloride.* (36°). Formed, together with some of the following isomeride, by treating propylene chloride with alcoholic KOH (Cahours, *C. R.* 31, 291). Obtained by heating propylidene chloride $CH_3.CH_2.CHCl_2$ with alcoholic KOH (Reboul, *A. Ch.* [5] 14, 462). Formed also by heating the neutral solution of the alkaline salts of the liquid αβ-di-chloro-butyric acid (Wislicenus, *B.* 20, 1010). Liquid. Br at 15° forms $C_3H_5ClBr_2$ (177°). Alcoholic KOH gives allylene. HBr gives $CH_3.CH_2.CHClBr$ (110°) and a small quantity of $CH_3.CHBr.CH_2Cl$ (121°).

Allo-**ω-chloro-propylene** $CHCl:CH.CH_3$. (33°). Formed by heating the neutral solution of the alkaline salts of αβ-di-chloro-butyric acid [63°] (Wislicenus, *B.* 20, 1010).

α-Chloro-propylene $CH_2:CCl.CH_3$. (23°) (O.; L.); (25·5°) (F.). S.G. ^{0} ·9307 (F.); ^{0} ·931 (O.). V.D. 2·83 (calc. 2·65). The chief product of the action of alcoholic KOH on propylene chloride. Formed also by treating $CH_3.CCl_2.CH_3$ (from acetone and PCl_5) with alcoholic KOH, with NH_3, or with AgOAc.

Reactions.—1. H_2SO_4 followed by water gives acetone (Oppenheim, *C. R.* 65, 354; *A. Suppl.* 6, 357).—2. *Water* at 160° also forms acetone.—3. Br gives $CH_2Br.CClBr.CH_3$ (c. 173°) (Friedel, *A. Ch.* [4] 16, 343).—4. Alcoholic KOH at 120° gives allylene (Friedel, *C. R.* 59, 294).—5. HI at 100° gives $CH_3.CClI.CH_3$.—6. Cl in sunshine forms $CH_2Cl.CCl_2.CH_3$ (127°). In the dark Cl forms $CH_2:CCl.CH_2Cl$.—7. HBr gives $CH_3.CBrCl.CH_3$ (93°).—8. HClO gives chloro-acetone (Linnemann, *A.* 138, 122).

αβ-Di-chloro-propylene $CH_2:CCl.CH_2Cl$. (α)-*Epidichlorhydrin.* (α)-*Chloro-allyl chloride.* (94°). S.G. ^{0} 1·236; ^{25} 1·204.

Formation.—1. Together with the following, by the action of Cl on $CH_3.CCl:CH_2$ in the shade (Friedel a. Silva, *C. R.* 73, 957; 74, 806; 75, 81; Fittig, *A.* 135, 359), or of KOH or NEt_3 on $CH_2Cl.CHCl.CH_2Cl$ (Reboul, *A. Suppl.* 1, 229; *C. R.* 95, 993).—2. From $CH_3.CCl_2.CH_2Cl$ and alcoholic KOH (F. a. S.).

Reactions.—1. Br forms $C_3H_4Cl_2Br_2$ (205°).—2. Fuming HCl at 100° gives $CH_3.CCl_2.CH_2Cl$.—3. H_2SO_4 followed by water gives chloro-acetone (Henry, *B.* 5, 186).—4. Alcoholic KOH gives $CH_2:CCl.CH_2OEt$ (110°).—5. ClOH gives *s*-di-chloro-acetone [42°] and $CH_2Cl.CCl_2.CH_2Cl$ (164°) (Henry, *C. R.* 94, 1428).—6. NEt_3 at 100° forms $CH_2:CCl.CH_2NEt_3Cl$ (Reboul, *C. R.* 95, 993).—7. *Sodium* gives allylene and propylene.—8. Alcoholic KCy followed by KOH gives tricarballylic acid and a little oxy-crotonic acid (Claus, *A.* 170, 126).

ωβ-Di-chloro-propylene $CHCl:CH.CH_2Cl$. β-*Epidichlorhydrin.* β-*Chloro-allyl chloride.* (106°) (F. a. S.); (110° cor.) (R.). S.G. $\frac{15}{4}$ 1·226 (R.); ^{0} 1·250 (F. a. S.). V.D. 3·83.

Formation.—1. Together with the preceding, by the action of solid KOH on $CH_2Cl.CHCl.CH_2Cl$ (F. a. S.).—2. In the pure state by treating $CH_2Cl.CH(OH).CH_2Cl$ with P_2O_5 (Hartenstein, *J. pr.* [2] 7, 310).—3. A by-product in the action of PCl_5 on acroleïn (Geuther, *Z.* 1865, 25; v. Romburgh, *Bl.* [2] 36, 549).

Reactions.—1. Cl gives $CH_2Cl.CHCl.CHCl_2$ (180°).—2. Does not unite with HCl.—3. Alcoholic KOH gives $CHCl:CH.CH_2OEt$ (123°).—4. Aqueous KOH gives β-chloro-allyl alcohol.—5. *Sodium* forms isoallylene $CH_2:C:CH_2$ (Hartenstein).—6. Br gives $CHClBr.CHBr.CH_2Cl$ (212°).

ωα-Di-chloro-propylene . $CH_3.CCl:CHCl$. *Allylene dichloride.* (75°) (F. a. S.); (78°) (P. a. K.).

Formation. — 1. From $CH_3.CCl_2.CH_2Cl$ by treatment with alcoholic KOH (Friedel a. Silva, *Bl.* [2] 17, 386; *J.* 1872, 322).—2. From tri-chloro-butyric aldehyde and aqueous KOH (Pinner a. Krämer, *A.* 158, 47; 179, 44).

Reactions.—1. Br forms $CH_3.CClBr.CHClBr$ (188°).—2. *Sodium* forms allylene $CH_3.C:CH$.

Di-chloro-propylene $CH_2:CH.CHCl_2$. *Allylidene chloride. Acroleïn chloride.* (85° cor.). S.G. $^{24\cdot5}$ 1·170. V.D. 3·83. Formed, together with $CHCl:CH.CH_2Cl$ and $CHCl:CH.CH_2OH$, by the action of PCl_5 on acroleïn (Geuther, *A.* 114, 36; *Z.* 1865, 25; v. Romburgh, *Bl.* [2] 36, 549).

Reactions.—1. Cl forms $CH_2Cl.CHCl.CHCl_2$ (180°).—2. KI or CaI_2 at 100° gives C_3H_4ClI (162°) (v. Romburgh, *R. T. C.* 1, 233).—3. Potassium acetate gives $C_3H_4(OAc)_2$ (c. 180°).—

4. *Sodium* has no action.—5. Alcoholic KOH gives $CH_2{:}CH.CHCl(OEt)$ (c. 118°).—6. NaOEt gives $CH_2{:}CH.CH(OEt)_2$ (Aronstein, *A. Suppl.* 3, 181). 7. Conc. HClAq at 100° changes it to the isomeric $CH_2Cl.CH{:}CHCl$.—8. NH_3 at 100° forms acrolein-ammonia.

Tri-chloro-propylene $CH_2Cl.CCl{:}CH_2Cl$. (142°). S.G. ^{20} 1·414. From $CH_2Cl.CCl_2.CH_2Cl$ and alcoholic KOH (Pfeffer a. Fittig, *A.* 135, 361).

Tri-chloro-propylene $CH_3.CCl{:}CCl_2$. (115°). S.G. ^{14} 1·387. From $CH_3.CCl_2.CHCl_2$ and alcoholic KOH (Borsche a. Fittig, *A.* 133, 117). Cl forms solid $C_3H_3Cl_5$.

Tri-chloro-propylene $C_3H_3Cl_3$. (139°). From the crude product of the chlorination of aldehyde (tri-chloro-butyric aldehyde) and aqueous NaOH (Pinner, *B.* 5, 207). Alcoholic KOH converts it into $C_3H_2Cl_2$.

Tetra-chloro-propylene $C_3H_2Cl_4$. (165°). From $C_3H_3Cl_5$ (derived from acetone) and alcoholic KOH (B. a. F.,

CHLORO-PROPYLENE GLYCOL *v.* GLYCERIN *chlorhydrin.*

CHLORO-PROPYLIDENE CHLORIDE *v.* TRI-CHLORO-PROPANE.

CHLORO-DI-ISOPROPYL-KETONE $C_3H_7.CO.C_3H_6Cl$. (142°). Prepared by passing Cl into di-iso-propyl-ketone at 0° (Barbaglia a. Gucci, *B.* 13, 1570; *G.* 11, 92). Liquid.

Di-chloro-di-isopropyl-ketone $C_6H_{12}Cl_2{:}CO$. (176°). Prepared by passing chlorine into di-isopropyl-ketone at the ordinary temperature (B. a. G.). Colourless liquid. Turpentine-like odour.

Tri-chloro-di-isopropyl-ketone $C_6H_{11}Cl_3{:}CO$. (about 229°). Prepared by passing Cl into boiling di-isopropyl-ketone (B. a. G.). Liquid with pungent turpentine-like odour.

CHLORO-ISOPROPYL NITRATE $CH_3.CH(NO_3).CH_2Cl$. (158°). S.G. ^{12} 1·28. From chloro-isopropyl alcohol HNO_3, and H_2SO_4 (Henry, *A. Ch.* [4] 27, 263).

αβ-**Di-chloro-propyl nitrate** $CH_2Cl.CHCl.CH_2NO_3$. (180°). S.G. ^{7} 1·3. From $CH_2Cl.CHCl.CH_2OH$ and HNO_3 (Henry, *B.* 7, 409).

Di-chloro-isopropyl nitrate $(CH_2Cl)_2CH.NO_3$. (180°–190°). S.G. ^{12} 1·465. Formed from $CH_2Cl.CH(OH).CH_2Cl$, HNO_3, and H_2SO_4 (Henry, *A.* 155, 167).

(*Py.* 3)-CHLORO-(*B.* 3)-ISOPROPYL QUINOLINE

$C_6H_4(C_3H_7)\left\langle\begin{array}{l}CH{:}CH\\ \quad\;|\\ N{:}CCl\end{array}\right.$

Chloro-cumoquinoline. Formed by heating isopropyl-carbostyril with PCl_5 (Widmann, *B.* 19, 265). Yellowish oil. Heavier than water. V. sol. alcohol, ether, benzene, &c., nearly insol. water. Sparingly volatile with steam. Weak base.—$B'_2H_2Cl_2PtCl_4$ [138°]; yellow monoclinic prisms.

CHLORO-PYRENE *v.* PYRENE.

CHLORO-PYRIDINE C_5H_4ClN *i.e.*

$N\left\langle\begin{array}{l}CH.CCl\\ CH{:}CH\end{array}\right\rangle CH$

(148°). V.D. 57 (obs.).

Formation.—1. By heating potassium pyrrol with chloroform in presence of ether; the residue after evaporation of the ether is boiled with dilute HCl to resinify the unaltered pyrrol, and after making alkaline with KOH, the chloro-pyridine is distilled over with steam (Ciamician a. Dennstedt, *G.* 11, 224, 300; *B.* 14, 1153).—2. By the action of CCl_4, chloral, or tri-chloro-acetic ether on pyrrol-potassium (Ciamician a. Dennstedt, *B.* 15, 1179).—3. From oxy-pyridine and PCl_5 (Lieben a. Haitinger, *M.* 6, 315).

Properties.—Pungent alkaline liquid; m. sol. water.

Reactions.—1. HI at 145° gives iodo-pyridine; at 200° it forms pyridine (L. a. H.)—2. Br and I form additive compounds.—3. *Sodium amalgam* forms chloro-piperidine $C_5H_{10}ClN$.

Salts.—B'HCl: deliquescent crystals.—$B'_2H_2PtCl_6aq$: monoclinic needles; *a*:*b*:*c* = 1·197:1:1·172; *β* = 109° 48′ (C. a. D.); *a*:*b*:*c* = 1·04:1:1·25; *β* = 72° 42′ (L. a. H.). Converted by heat into B'_2PtCl_4.

Hexahydride $C_5H_{10}ClN$. *Chloropiperidine.* From chloro-pyridene by reduction with sodium amalgam or with Zn and HCl.—$B'_2H_2PtCl_6aq$: monoclinic needles; *a*:*b*:*c* = 1·209:1:1·094; *β* = 113° 35′.

Di-chloro-pyridine $C_5H_3Cl_2N$. [67°]. Formed by heating barium pyridine-di-sulphonate with PCl_5 (Koenigs a. Geigy, *B.* 17, 1833). Volatile with steam. Glistening plates. V. sol. alcohol, sl. sol. water. $HgCl_2$ added to the aqueous or alcoholic solution precipitates a double salt which forms long fine needles [183°].—$B'_2H_2Cl_2PtCl_4$ 2aq: fine yellow needles.

Di-chloro-pyridine $C_5H_3Cl_2N$. [72°]. Formed, together with other products, by the action of dry chlorine upon dry pyridine. Slender white needles; sol. pyridine and alcohol, insol. water. Has an agreeable aromatic odour (Keiser, *Am.* 8, 308).

Tri-chloro-pyridine $C_5H_2Cl_3N$. [50°]. Formed, together with di-chloro-pyridine [67°] by heating barium pyridine-di-sulphonate with PCl_5 (Koenigs a. Geigy, *B.* 17, 1832). Volatile with steam. Long flat needles. Sol. alcohol, nearly insol. water.

Tri-chloro-pyridine (?) $C_5H_2Cl_3N$. [65°]. Formed, along with chloro-oxy-pyridine carboxylic acid (*q. v.*) by treating nicotinic acid with PCl_5, and warming the product with H_2SO_4 (80 p.c.) (Seyfferth, *J. pr.* [2] 34, 261). Long needles (by sublimation); v. sl. sol. water, sol. alcohol, ether, and benzene.

CHLORO-PYRIDINE-CARBOXYLIC ACID $C_6H_4ClNO_2$ *i.e.* $C_5H_3ClN.CO_2H$. *Chloro-picolinic acid.* [180°]. From picolinic acid by treatment with PCl_5, the resulting chloro-picolines, including $C_5H_3ClNCCl_3$, being warmed with H_2SO_4 (80 p.c.) (Seyfferth, *J. pr.* [2] 34, 249).

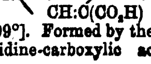
Properties.—Dendritic needles or prisms, sl. sol. cold water; extracted by ether from aqueous solution.

Salts.—CaA'_2 aq.

Reaction.—1. HI reduces it to picolinic acid; in presence of phosphorus, picoline is also formed.

Chloro-pyridine carboxylic acid $C_5H_3NCl.CO_2H$. [168°]. *Chloro-picolinic acid.* From di-chloro-pyridine carboxylic acid, HOAc, and HI at 150° (Ost, *J. pr.* [2] 27, 284). Needles or prisms (containing aq).—BaA'_2 2aq.

Chloro-pyridine-carboxylic acid. $C_5H_3NCl.CO_2H$ *i.e.*



$N\left\langle\begin{array}{l}CCl.CH{:}CH\\ CH{:}C(CO_2H)\end{array}\right.$

Chloro-nicotinic acid. [199°]. Formed by the action of PCl_5 on oxy-pyridine-carboxylic acid [303°]

(Pechmann a. Welsh, *B.* 17, 2392; *C. J.* 47, 145). Sublimable. Glistening plates. Sol. water, alcohol, ether, and acetic acid, sl. sol. benzene. By tin and HCl it is reduced to nicotinic acid.

Di-chloro-pyridine carboxylic acid $C_5H_2NCl_2.CO_2H$. *Di-chloro-nicotinic acid.* [138°]. One of the products of the action of warm H_2SO_4 (80 p.c.) on the oily product got from nicotinic acid and PCl_5 (Seyfferth, *J. pr.* [2] 34, 262). Clumps of needles (from water).

Ethyl ether EtA′. [50°].

Di-chloro-pyridine carboxylic acid $C_5H_2Cl_2N.CO_2H$. *Di-chloro-picolinic acid.* [180°].

Preparation.—The mixture of penta- and hexa-chloro-picolines obtained by boiling (10 g.) comenamic acid with (20 g.) dilute (80 p.c.) H_2SO_4 for an hour contains dichloro-, dichloroxy-, and chloroxy-picolinic acids. The first acid is extracted by chloroform, the other two are separated by means of their lime salts, the calcic chloroxy-picolinate being the more soluble (Ost, *J. pr.* [2] 27, 281). *Properties.*—Slender needles. (containing aq); sl. sol. cold water, v. sol. hot water and chloroform. Gives no odour with Fe_2Cl_6. Reduced by HI in glacial acetic acid to picolinic acid.

Salts.—NaA′. Trapezoidal plates.—KA′. Triangular and trapezoidal plates, often twins.

Tetra-hydride $C_5H_7ClN.CO_2H$. [c. 268°]. From the above by tin and HCl. Laminæ (from water).—B′HCl.

Di-chloro-pyridine-carboxylic acid

$C_5H_2N(Cl)_2(CO_2H)$ *i.e.*

$\mathrm{N}\!\left\langle\begin{matrix}\mathrm{CCl{:}CH}\\ \mathrm{CCl.CH}\end{matrix}\right\rangle\!\mathrm{C.CO_2H}$ (?).

[210°]. Formed by heating citrazinic acid with PCl_5 (Behrmann a. Hofmann, *B.* 17, 2691). Colourless plates. Sol. alcohol, v. e. sol. ether, sl. sol. water.—A′Ag: colourless needles.

TETRA-CHLORO-PYRIMIDINE $C_4N_2Cl_4$ *i.e.*

$$\begin{array}{l}\mathrm{CCl{=}CCl{-}CCl}\\ |\qquad\qquad\quad\|\\ \mathrm{N{=}CCl{-}N}\end{array}$$

[68°]. Formed by heating alloxan (1 pt.) with PCl_5 (6 pts.) and $POCl_3$ (5 pts.) for 8 hrs. at 120°–130°. Colourless pearly plates, of camphor-like smell. Volatile with steam (Ciamician a. Magnaghi, *G.* 16, 173; *B.* 18, 3445).

TETRA-CHLORO-PYROCATECHIN $C_6Cl_4(OH)_2$ [1:2:3:4:5:6]. [174°]. Obtained by passing chlorine into a hot, strong solution of pyrocatechin in acetic acid. Colourless needles or thick plates. On oxidation it gives tetra-chloro-*o*-quinone $C_6Cl_4O_2$ (Zincke, *B.* 20, 1779).

PER-CHLORO-PYROCOLL $C_{10}N_2O_2Cl_6$. [above 320°]. Formed, together with the tetra-chloride, by heating pyrocoll (1 g.) with PCl_5 (12 g.) at 220° for 6 hrs. (Ciamician a. Danesi, *G.* 12, 31). Scales. Insol. cold HOAc. Changed by long boiling into tri-chloro-pyrrol carboxylic acid.

Tetra-chloride $C_{10}N_2O_2Cl_{10}$. Formed as above (C. a. D.). Pearly triclinic prisms (from HOAc). Sl. sol. cold HOAc.

Octo-chloride $C_{10}N_2O_2Cl_{14}$. [147°]. From per-chloro-pyrocoll and PCl_5 at 250°. Sublimes a little above 100°. Smells like camphor. By reduction with zinc-dust and acetic acid it yields tetra-chloro-pyrrol. Heated with water at about 130° it decomposes into (α)-di-chloro-acrylic acid [86°], NH_3, CO_2, and HCl. By boiling with dilute acetic acid it is resolved into di-chloro-maleïmide, CO_2 and HCl (Ciamician a. Silber, *G.* 13, 320; *B.* 16, 2389).

TRI-CHLORO-PYROGALLOL $C_6Cl_3(OH)_3$. *Tri-chloro-pyrogallic acid.* [c. 185°] (H. a. S.). A mixture of pyrogallol (5 g.) and acetic acid (12·5 c.c. of 60 p.c.) is kept cool and dry chlorine is passed in. In half-an-hour tri-chloro-pyrogallol crystallises out (Webster, *C. J.* 45, 205).

Properties.—Fine needles (containing 3aq). Resembles tri-bromo-pyrogallol, notably in giving a deep blue colour when baryta is added to its ethereal solution. When anhydrous it melts about 177° (W.); when hydrated it melts at 115° (W.) or 75° (H. a. S.). Sol. water, but slowly decomposed by it. Sol. acetic acid, benzene, chloroform, CS_2, and CCl_4. V. sol. alcohol and ether. Reduces ammoniacal $AgNO_3$ to a mirror.

Reactions.—1. *Sodium sulphite* gives a fugitive red colour.—2. Conc. HNO_3 decomposes it. 3. Treated with chloroform saturated with chlorine, it turns wine-red, then effervesces and becomes yellow. On evaporation, crystals of 'leucogallol,' $C_{18}H_6Cl_6O_{12}$ 2aq (Stenhouse a. Groves, *C. J.* 28, 704), separate. Hence pyrogallol added to chloroform saturated with chlorine is converted into 'leucogallol,' the intermediate tri-chlorinated body being found to very small extent.

Salts.—$Ba_3(C_6Cl_3O_3)_2$ 6aq (Hantzsch a. Schniter, *B.* 20, 2033).—$Cu_3(C_6Cl_3O_3)_2$ 6aq.

Acetyl derivative $C_6Cl_3(OAc)_3$. [122°]. Needles.

βγ-**DI-CHLORO-PYROMUCIC ACID** $C_5H_2Cl_2O_3$ [169°]. Obtained by the action of conc. alcoholic KOH upon pyromucic-ether-tetra-chloride (formed by combination with chlorine in the cold) (Denaro, *G.* 16, 333; Hill a. Jackson, *B.* 20, 252). Felted needles. Sol. hot water, v. sol. alcohol and ether, m. sol. boiling benzene or chloroform, sl. sol. cold benzene or chloroform. Warmed with excess of bromine-water it is converted into mucochloric acid with evolution of CO_2. By boiling with dilute HNO_3 (1:2) it yields mucochloric acid and di-chloro-maleïc acid.

Salts.—A'_2Ba 3aq: fine needles, sl. sol. cold water.—A'_2Ca 4aq: long needles, sl. sol. cold water.—A′K: rather sparingly soluble small prisms.—A′Ag: fine needles.

Ethyl ether A′Et: [64°], slender needles.

Amide $C_4HCl_2O.CO.NH_2$: [176°], felted needles.

CHLORO-PYROTARTARIC ACIDS.

Ita-chloro-pyrotartaric acid $C_5H_7ClO_4$. [140°–145°]. (c. 230°). From itaconic acid and conc. HCl at 130 (Swarts, *Z.* 1866, 721). In a current of dry air at 150° it forms an anhydride. Boiling water or alkalis form paraconic acid, $C_5H_6O_4$, which rapidly changes to itamalic acid, $C_5H_8O_5$.

Diethyl ether Et_2A''. (251°).

Citra-chloro-pyrotartaric acid $C_5H_7ClO_4$. [129°]. From citraconic anhydride and cold fuming HCl. Formed also by the union of mesaconic acid with HCl (Fittig, *A.* 188, 51). Tables. Boiling water splits it up into HCl and mesaconic acid. Boiling alkalis form methacrylic acid.

Ita-di-chloro-pyrotartaric acid $C_5H_6Cl_2O_4$. (S.).

Citra-di-chloro-pyrotartaric acid $C_5H_6Cl_2O_4$. From citraconic acid and Cl (Swarts, *J.* 1873, 582; *Bull. Acad. Roy. Belg.* [2] 33, No. 1). On distillation it gives HCl and citraconic anhydride. Boiling water converts it into chloro-citramalic acid $C_5H_7ClO_5$. The Na salt when boiled in aqueous solution gives chloro-methacrylic acid.

TETRA-CHLORO-PYRROL C_4Cl_4NH. [110°]. (261°) at 754 mm.

Formation.—1. Together with di-chloro-maleïc acid and NH_3, by treating pyrrol with NaOCl. — 2. By reduction of per-chloro-pyrocoll-octo-chloride with zinc-dust and acetic acid.—3. By heating di-chloro-maleïmide with PCl_5 at 160°.—4. By reducing with zinc-dust and HCl the per-chloride C_4Cl_7N which is obtained by heating di-chloro-maleïmide with PCl_5 at 200° (Ciamician a. Silber, *B.* 16, 2390; 17, 554, 1743; *G.* 14, 356). Very volatile. Long silky plates. V. sol. alcohol and ether, sl. sol. water. Dissolves in alkalis. The ammoniacal solution gives a white pp. with $AgNO_3$. It dissolves in strong H_2SO_4 with an intense reddish-brown colour; on adding a few drops of water this changes to violet, and by further addition of water gives a green pp. which dissolves in KOH with an intense orange colour.

(α) - **TRI - CHLORO - PYRROL - CARBOXYLIC ACID** $C_5Cl_3H_2NO_2$ *i.e.* $C_4HCl_3N.CO_2H$.

Prepared by heating per-chloro-pyrocoll with caustic potash.

$$C_{10}Cl_6N_2O_2 + 2KOH = 2C_4Cl_3HNCO_2K$$

(Ciamician a. Danesi, *G.* 12, 34). Long silky needles (containing aq). V. sol. alcohol and ether, sl. sol. water; its solutions give with lead acetate a white pp., and with ferric chloride an intense red colouration. It decomposes with violence at 150°. BaA'_2aq: scales, m. sol. alcohol, sl. sol. water.

TRI-CHLORO-PYRUVIC ACID *Hydrate* $CCl_3.C(OH)_2.CO_2H$. *Tri-chloro-isoglyceric acid.* [102°]. Prepared by saponification of tri-chloro-acetyl cyanide with HCl (Claisen a. Antweiler, *B.* 13, 1937). Formed also, together with tri-carballylic acid, by treating gallic acid, salicylic acid, or phenol with HCl and $KClO_3$ (Schreder, *A.* 177, 282). Colourless prisms. V. sol. water, alcohol, ether, acetic acid, and acetone; m. sol. C_6H_6 and CS_2; insol. petroleum ether. Reduces Fehling's solution and ammoniacal $AgNO_3$. Warmed with an alkali it readily splits up into chloroform and an oxalate.—A''Ba: small soluble prisms.—NaA'*x*aq (Hofferichter, *J. pr.* [2] 20, 198).

Amide $CCl_3.C(OH)_2.CONH_2$. [127°]. Prepared by the action of cold aqueous HCl on tri-chloro-acetyl cyanide. Colourless crystals. Sol. water, alcohol, ether, and acetone; sl. sol. CS_2, C_6H_6, and $CHCl_3$. On heating it loses H_2O and is converted into a compound of the formula $C_3Cl_3O_2H_2N$, which forms small plates or needles of melting-point [218°], which are sublimable and sol. ether, sl. sol. water.

Nitrile v. TRI-CHLORO-ACETYL CYANIDE.

ω-**CHLORO-PYRUVIC ALDEHYDE** $CH_2.CO.CClO$.

Oxim $CH_3.CO.CCl(NOH)$: v. CHLORO-ISONITROSO-ACETONE.

CHLORO-QUARTENYLIC ACID v. CHLORO-CROTONIC ACID.

DI-CHLORO-QUINALDINE v. DI-CHLORO-(*Py.* 3)-METHYL-QUINOLINE.

(*B.* 1)-**CHLORO-QUINOLINE** C_9H_6ClN *i.e.*

$$\begin{array}{l}\mathrm{CH{:}CCl.C.CH{:}CH}\\ \ \mid\qquad\quad\ \Vert\qquad\mid\\ \mathrm{CH{:}CH.C.N=CH}\end{array}$$

[32°]. (268°). Formed together with the (*B.* 3)-isomeride by heating *m*-chloro-aniline with glycerin, nitrobenzene, and H_2SO_4 (La Coste, *B.* 18, 2940). Formed also from the corresponding amido-quinoline by Sandmeyer's reaction (Freydl, *M.* 8, 583). Needles or thick glistening prisms. The bichromate forms long yellow needles, [165°]; sol. hot water, sl. sol. cold.

(*B.* 3)-Chloro-quinoline

$$\begin{array}{l}\mathrm{CH{:}CH.C.CH{:}CH}\\ \ \mid\qquad\quad\ \Vert\qquad\mid\\ \mathrm{CCl{:}CH.C.N:CH}\end{array}$$

(c. 257°). Formed, together with the (*B.* 1)-isomeride, by heating *m*-chloro-aniline with glycerine, nitrobenzene, and H_2SO_4. Liquid; solidifies in a freezing mixture. Volatile with steam. V. sol. alcohol, ether, and benzene; nearly insol. water. Is probably not quite pure (La Coste, *B.* 18, 2940).

Salts. — B'HCl: colourless tables. $B'_2H_2Cl_2PtCl_4$ 2aq: orange silky needles. $B'_2H_2Cr_2O_7$: [119°] fine yellow silky needles; S. ·25.

Methylo-iodide B'MeI: [232°]; long yellow needles. On oxidation with $KMnO_4$ it gives the formyl-derivative of chloro-methyl-amido-benzoic acid, and chloro-methyl-isatin (La Coste a. Bodewig, *B.* 17, 926; 18, 428).

(*B.* 2)-Chloro-quinoline

$$\begin{array}{l}\mathrm{CCl{:}CH.C.CH{:}CH}\\ \ \mid\qquad\quad\ \Vert\qquad\mid\\ \mathrm{CH{:}CH.C.N:CH}\end{array}$$

(256°). Prepared by heating *p*-chloraniline with glycerine, nitro-benzene, and H_2SO_4; the yield is 100 p.c. (La Coste, *B.* 15, 560). Colourless liquid.

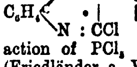
Salts.—BHCl: soluble colourless needles. $(BHCl)_2PtCl_4$ 2aq: yellow crystalline pp.

Methylo-iodide B'MeI: soluble crystalline solid.—$(BMeCl)_2PtCl_4$: orange crystalline pp.

(*Py.* 3)-Chloro-quinoline C_9H_6NCl. [38°]. (267°). Formed by the action of PCl_5 on carbostyril or oxy-carbostyril (Friedländer a. Ostermayer, *B.* 15, 333). Volatile with steam. Long needles. V. sol. alcohol, ether, benzene and ligroïn, nearly insol. water. On heating with water to 120° it gives carbostyril.

Chloro-quinoline C_9H_6ClN. Formed by heating cynurin with PCl_5 and $POCl_3$ (Kretschy, *M.* 2, 77).—$B'H_2PtCl_6$ 2aq.

(*Py.* 1,3) - **Di - chloro - quinoline, called** (γ),



$$\mathrm{C_6H_4}\!\left\langle\begin{array}{l}\mathrm{CCl{:}CH}\\ \qquad\quad\mid\\ \mathrm{N:CCl}\end{array}\right.$$

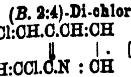
[67°]. (281°). **Formed by the** action of PCl_5 on (*Py.* 1,3)-di-oxy-quinoline (Friedländer a. Weinberg, *B.* 15, 2683) or on (γ)-chloro-carbostyril (Baeyer a. Bloem, *B.* 15, 2150). Slender needles; sol. alcohol, ether, and benzene, nearly insol. water.

(*B.* 1:4)-**Di-chloro-quinoline**

$$\begin{array}{l}\mathrm{CH{:}CCl.C.CH{:}CH}\\ \ \mid\qquad\quad\ \Vert\qquad\mid\\ \mathrm{CH{:}CCl.C.N=CH}\end{array}$$

[93°]. **Prepared by heating** (3:6:1)-di-chloro-aniline with glycerin, nitro-benzene, and H_2SO_4 (La Coste, *B.* 15, 561). Volatile undecomposed. Colourless needles or tables. Sol. alcohol and ether.

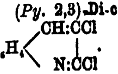
(*B.* 2:4)-Di-chloro-quinoline



$$\begin{array}{l}\mathrm{CCl{:}CH.C.CH{:}CH}\\ |\qquad\quad \|\qquad\quad |\\ \mathrm{CH{:}CCl.C.N : CH}\end{array}$$

. [104°]. Prepared by heating (4:2:1)-di-chloro-aniline with glycerin, nitro-benzene, and H_2SO_4 (La Coste, *B.* 15, 561). Long fine colourless needles. Sl. sol. alcohol.

(*Py.* 2,3)-Di-chloro-quinoline $C_9H_5Cl_2N$ *i.e.*



$$C_6H_4\left\langle\begin{array}{l}\mathrm{CH{:}CCl}\\ \qquad |\\ \mathrm{N{:}CCl}\end{array}\right.$$

. [105°]. Weak base. Prepared by treating hydro-carbostyril with PCl_5 and distilling the product with steam; the yield is 20-30 p.c. (Baeyer, *B.* 12, 1320). Insol. water, sol. alcohol, ether, and C_6H_6. On reduction with HI it gives quinoline.

Tri-chloro-quinoline $C_9H_4Cl_3N$. [108° uncor.]. Formed by heating phenyl-malonamic acid (malonanilidic acid) $CO_2H.CH_2.CO.NHPh$ with benzene and PCl_5 (Rügheimer, *B.* 17, 736). Long colourless needles. Volatile with steam. Sol. alcohol, benzene, and ligroïn. By heating with an acetic acid solution of HI at 240° it is reduced to quinoline.

Tri-chloro-quinoline $C_9H_4Cl_3N$. [161°]. From di-chloro-carbostyril and PCl_5 (Friedländer a. Weinberg, *B.* 15, 1425). Slender needles (from alcohol); slightly volatile with steam.

Tri-chloro-quinoline $C_9H_4Cl_3N$. [211°]. Formed by acting on the borate of (*B.* 4)-chloro-quinoline with bleaching powder solution (Emhorn and Lauch, *A.* 243, 361). Needles (from acetic ether).

(*Py.* 2)-CHLORO-ISOQUINOLINE C_9H_6ClN *i.e.*

$$C_6H_4\left\langle\begin{array}{l}\mathrm{CH{:}CCl}\\ \qquad\ |\\ \mathrm{CH{:}N}\end{array}\right.$$

(?). [45°-48°]. (280°) at 753 mm. Formed by heating the di-chloro-derivative [123°] with HI and P at 170°. By more prolonged action at 200° it is completely di-chlorinated to isoquinoline. Long colourless needles. Weak base (Gabriel, *B.* 19, 1655, 2356).

(*Py.* 2:4)-Di-chloro-isoquinoline $C_9H_5Cl_2N$ *i.e.*

$$C_6H_4\left\langle\begin{array}{l}\mathrm{CH{:}CCl}\\ \qquad\ |\\ \mathrm{CCl{:}N}\end{array}\right.$$

. [123°]. (306°). Formed by heating the imide of phenyl-acetic-*o*-carboxylic acid

$$C_6H_4\left\langle\begin{array}{l}\mathrm{CH_2.CO}\\ \qquad\ |\\ \mathrm{CO.\ NH}\end{array}\right.$$

with $POCl_3$ (3 pts.) at 150°-170°. Very long flat needles (from alcohol). V. sol. chloroform, benzene, ether, and hot alcohol. Slowly volatilises with steam. By HI and P it is first reduced to the mono-chloro-derivative and finally to isoquinoline (Gabriel, *B.* 19, 1655, 2355).

CHLORO-QUINONE $C_6H_3ClO_2$. [57°].

Formation.—1. By distilling cupric quinate (25 g.) with NaCl (60 g.), MnO_2 (40 g.), H_2SO_4 (100 g.), and water (170 g.) (Städeler, *A.* 69, 300). 2. By oxidation of chloro-hydroquinone with CrO_3 (Levy a. Schultz, *A.* 210, 144; *B.* 13, 1428). 3. By adding aqueous K_2CrO_4 to a slightly acid solution of chloro-amido-phenol sulphate (Kollrepp, *A.* 234, 14).

Properties.—Long yellow trimetric needles; $a{:}b{:}c = \cdot47{:}1{:}1\cdot71$; v. sol. ether, m. sol. alcohol, HOAc, and hot water. Turns the skin purple. Reduced by SO_2 to chloro-hydroquinone.

Reactions.—1. When mixed with *m-nitro-aniline* in benzene solution, dark green crystals of $C_6H_3Cl(O)_2(NH_2.C_6H_4.NO_2)_2$ separate. This breaks up into its constituents even on recrystallising from benzene (Niemeyer, *A.* 228, 322). 2. *p-Toluidine* forms, in the same way, white plates [90°] (${}^{\times}C_6H_3Cl(OH)_2(C_7H_9N)_2$?)

(*α*)-Di-chloro-quinone $C_6H_2Cl_2O_2$ [5:2:4:1]. [159°].

Formation.—1. One of the products of the distillation of cupric quinate with MnO_2, NaCl, and H_2SO_4 (Städeler, *A.* 69, 300).—2. From benzene and Cl_2O (Carius, *A.* 143, 315).—3. Together with chloro-benzene and tri-chloro-phenomalic acid, by dissolving benzene (48 g.) in H_2SO_4 (300 g.), diluting with water (150 g.), and, after cooling, adding more benzene (100 g.) and $KClO_3$ (150 g.). The mixture is left to itself for a week (C.).—4. By the oxidation of (*α*)-di-chloro-hydroquinone with conc. HNO_3 (Levy a. Schultz, *B.* 13, 1428; *A.* 210, 150).—5. By oxidation of di-chloro-*p*-phenylene-diamine [164°] with $K_2Cr_2O_7$ and H_2SO_4 (Möhlau, *B.* 19, 2010).—6. By oxidation of *p*-di-chloro-aniline with $K_2Cr_2O_7$ and H_2SO_4.—7. From quinone by two alternate treatments with HCl and with Fe_2Cl_6 (Levy, *B.* 18, 2366).—8. By adding K_2CrO_4 to a solution of di-chloro-amido-phenol sulphate (Kollrepp, *A.* 234, 15).

Properties. — Yellow monoclinic crystals; $a{:}b{:}c = 1\cdot15{:}1{:}2\cdot21$; $\beta = 56°\ 26'$ (Grünling); $a{:}b{:}c = 1\cdot09{:}1{:}1\cdot84$; $\beta = 89°\ 11'$ (Fock, *Z. K.* 7, 40). Sol. ether and chloroform, nearly insol. alcohol, insol. water. Volatile with steam. SO_2 reduces it to di-chloro-hydroquinone [172°].

Reactions.—1. *Aniline* in acetic acid solution, in presence of some HCl, forms blue plates of the anilide $C_6HCl_2O_2(NPhH)$ [5:2:4:1:3] [180°], which dissolves in conc. H_2SO_4 giving a deep-blue liquid (Niemeyer, *A.* 228, 332).—2. If, after warming with aniline, the hot solution is treated with HOAc, lustrous brown plates of the dianilide $C_6Cl_2O_2(NPhH)_2$ [290°] are formed. This is the so-called 'chloranil-anilide' obtained from tetra-chloro-quinone and aniline.—3. *m-Nitro-aniline* forms dark green crystals of $C_6H_2Cl_2O_2(NH_2.C_6H_4.NO_2)_2$ [110°] which may be crystallised from hot benzene (Niemeyer, *A.* 228, 322).—4. *p-Toluidine* forms a crystalline compound [115°] (${}^{\times}C_6H_2Cl_2O_2(C_7H_9N)_2$?).

(*β*)-Di-chloro-quinone $C_6H_2Cl_2O_2$ [2:6:1:4]. [120°].

Formation.—1. By oxidation of trichloro-phenol with HNO_3, or a mixture of HNO_3 and H_2SO_4 (Faust, *Z.* 1867, 727; Weselsky, *B.* 3, 646; Levy a. Schultz, *B.* 13, 1428; Guareschi a. Daccomo, *B.* 18, 1170).—2. In small quantity by treating di-chloro-nitro-phenol [125°] with HNO_3 and H_2SO_4 (Armstrong, *Z.* 1871, 521).—3. By oxidation of di-chloro-*p*-phenylene-diamine with CrO_3 (Levy, *B.* 16, 1445). Yellow trimetric crystals, $a{:}b{:}c = \cdot7127{:}1{:}2\cdot027$. V. sol. boiling alcohol, v. sl. sol. hot water. Turns the skin brown. Readily sublimes. Volatile with steam. SO_2 forms (*β*)-di-chloro-hydroquinone [158°].

Reactions.—1. *Aniline* (1 mol.) in alcoholic solution containing a little HCl, forms bluish-violet needles or plates of the anilide $C_6HCl_2O_2(NPhH)$ [154°]. This is sol. alcohol and ether, and gives a violet-blue solution in conc. H_2SO_4 (Niemeyer, *A.* 228, 332).—2. Excess of *aniline* added to an alcoholic or acetic acid *solution forms $C_6HClO_2(NPhH)_2$ [3:1:4:6:3] [262°]. This forms lustrous brown plates, sl. sol. alcohol and benzene, m. sol. hot HOAc (N.).*—3. *m-Nitro-aniline* forms glittering dark green prisms of $C_6HCl_2O_2(NH.C_6H_4.NO_2)_2$ [112°].—4. *p-Toluidine forms, in the same way, slender needles [73°] (*$C_6H_2Cl_2(OH)_2C_7H_9N$*?).*

Tri-chloro-quinone $C_6HCl_3O_2$. [163°].

Formation.—1. By chlorinating quinone (Woskresensky, *J. pr.* 18, 419).—2. By boiling quinic acid with MnO_2 and HCl (Städeler, *A.* 69, 318).—3. Together with tetrachloroquinone, by treating phenol with $KClO_3$ and aqueous HCl (Graebe, *A.* 146, 9; Stenhouse, *C. J.* 21, 141).—4. From benzene and CrO_2Cl_2 (Carstanjen, *B.* 2, 633).—5. By dropping sodium hypobromite solution slowly into a solution of the hydro-chloride of tri-chloro-*p*-amido-phenol; the pp. is re-crystallised from alcohol (M. Andresen, *J. pr.* [2] 28, 422).—6. From *p*-amido-phenol (*q. v.*) and bleaching powder (Schmitt a. Andresen, *J. pr.* [2] 23, 436).

Properties.—Yellow prisms. May readily be sublimed. Does not colour the skin. Insol. water, sol. hot alcohol, v. sol. ether. Dilute aqueous KOH dissolves it, forming di-chloro-di-oxy-quinone (chloranilic acid).

Reactions.—1. With alcoholic solution of *aniline* it gives glittering plates of di-chloro-quinone-di-anilide: $2C_6HCl_3O_2 + 3PhNH_2 = C_6(NPhH)_2Cl_2O_2 + C_6HCl_3(OH)_2 + PhNH_2HCl$. This substance crystallises from benzene in tablets which have a bluish lustre (M. Andresen, *J. pr.* [2] 28, 423).—2. *Aniline* (1 mol.) forms lustrous leaflets of $C_6HClO_2(NPhH)_2$. This forms a blue solution in conc. H_2SO_4 (Schultz, *B.* 10, 1792; *A.* 210, 180).—3. *Aniline* treated with excess of the quinone forms blue plates of $C_6Cl_3O_2(NPhH)$ (Niemeyer, *A.* 228, 332).—4. *m-Nitro-aniline* forms lustrous dark-green prisms of $C_6HCl_2O_2(NH_2.C_6H_4.NO_2)_2$ [108°] (N.).—5. PCl_5 at 190° gives C_6Cl_6.—6. AcCl gives the di-acetyl derivative of tetra-chloro-hydroquinone.—7. Boiling conc. aqueous HCl forms tetra-chloro-hydroquinone.

Tetra-chloroquinone $C_6Cl_4O_2$.

Formation.—1. By the action of a mixture of $KClO_3$ and HCl on quinone, aniline, phenol, tri-chloro-phenol, di-nitro-phenol, tri-nitro-phenol, salicin, salicylic acid, isatin, quinic acid, tyrosine, *m*-amido-benzoic acid, &c. (Hofmann, *A.* 52, 55; Hesse, *A.* 114, 303; Staedeler, *A.* 69, 326; 116, 99; Stenhouse, *A.* 78, 4; *A. Suppl.* 6, 209; Erlenmeyer, *J.* 1861, 404; *N. Jahr. Pharm.* xvi. 292).—2. By passing chlorine into an alcoholic solution of chloro-isatin (Erdmann, *A.* 48, 309).—3. From penta-chloro-phenol and fuming HNO_3 (Merz a. Weith, *B.* 5, 460).—4. Prepared by oxidation of tetrachlorohydroquinone (Levy a. Schultz, *B.* 13, 1429).—5. By heating trichloroquinone (5 g.) for 12 hours with fuming HCl (100 c.c.). The product is oxidised by strong HNO_3 and recrystallised from alcohol (Andresen, *J. pr.* [2] 28, 425).—6. From *s*-tetra-chloro-benzene [137°] and fuming HNO_3 (Beilstein a. Kurbatoff, *A.* 192, 236).—7. From phenol and chloride of iodine (Stenhouse, *C. J.* 23, 6).—8. From di-chloro-di-oxy-quinone and PCl_5.

Properties.—Pale yellow lustrous scales. Monoclinic; $a:b:c = 1{\cdot}52:1:3{\cdot}00$; $\beta = 73°56'$ (Fork, *Z. K.* 7, 40). When heated gently it sublimes without melting. Insol. water, v. sl. sol. cold alcohol, m. sol. ether. Not attacked by HNO_3, by HCl, or by boiling conc. H_2SO_4. SO_2 reduces it to tetra-chloro-hydroquinone. Boiling HCl or HBr also reduce it to the same body.

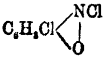
Reactions.—1. Conc. aqueous $KHSO_3$ forms 'potassium thiochronate' $C_6(OH)O_2(SO_4K)(SO_3K)_2$. Dilute $KHSO_3$ gives $C_6Cl_2(OH)_2(SO_3K)_2$.—2. Aqueous KOH forms a purple solution containing $C_6Cl_2(OK)_2O_2$.—3. AcCl at 170° gives Cl and $C_6Cl_4(OAc)_2$ (Graebe, *A.* 146, 12).—4. PCl_5 at 180° gives C_6Cl_6.—5. Aqueous NH_3 gives $C_6Cl_2(NH_2)(OH)O_2$ (Erdmann, *J. pr.* 22, 287; Laurent, *A. Ch.* [3] 3, 493).—6. Alcoholic NH_3 forms $C_6Cl_2(NH_2)_2O_2$.—7. An alcoholic solution of *aniline* reacts thus: $C_6Cl_4O_2 + 4NPhH_2 = C_6Cl_2(NPhH)_2O_2 + 2NPhH_2,HCl$ (Andresen, *J. pr.* [2] 28, 426).—8. *m-Nitro-aniline* forms almost black crystals of $C_6Cl_4O_2(NH_2.C_6H_4.OH)_2$ (Niemeyer, *A.* 228, 322).—9. A hot aqueous solution of $NaNO_2$ converts it into nitranilic acid (Nef, *B.* 20, 2027).—10. By warming an acetic acid solution of *p*-amido-xylenol (4 pts.) with chloranil (1 pt.) there is formed a colouring matter $C_{24}H_{26}N_2O_3$. Sol. alcohol, ether, benzene, and acetone, insol. water. Dissolves in alkalis with a blue colour, in conc. H_2SO_4 with a greenish-blue. By CrO_3 it is oxidised to *p*-xyloquinone (Sutkowski, *B.* 20, 980).

Tetra-chloro-*o*-quinone $C_6Cl_4O_2$ [1:2:3:4:5:6]. [132°]. Obtained by oxidation of tetra-chloro-pyrocatechin with HNO_3, or directly by passing chlorine into a hot acetic acid solution of pyrocatechin until it assumes a deep reddish-yellow colour. Dark-red crystals. V. sol. acetic acid (Zincke, *B.* 20, 1779).

p-**DI-CHLORO-QUINONE-DI-CARBOXYLIC-ETHYL-ETHER** $C_6Cl_2O_2(CO_2Et)_2$ [1:4:2:5:3:6]. [195°]. Formed by the action of chlorine upon quinone-di-hydro-di-carboxylic ether (di-oxy-terephthalic ether) or upon succinyl-succinic ether, suspended in alcohol. Greenish-yellow needles. Sol. acetic acid and chloroform, sl. sol. alcohol and ether. The Cl atoms are extremely mobile: thus by very dilute NaOH it is dissolved with formation of di-oxy-quinone-di-carboxylic ether; by NH_3 or amines it is readily converted into di-amido-quinone-di-carboxylic ether or its alkyl-derivatives. It is reduced by zinc-dust and acetic acid to the colourless di-chloro-hydroquinone-di-carboxylic ether (di-chloro-di-oxy-terephthalic ether, *q.v.*) (Hantzsch a. Zeckendorf, *B.* 20, 1310).

Dihydride $C_6H_2O_2Cl_2(CO_2Et)_2$. The colourless di-chloro-di-oxy-terephthalic ether becomes intense greenish-yellow when melted, changing to the tautomeric dihydride of tetra-chloro-quinone di-carboxylic ether. The colourless body dissolves in benzene, chloroform, and conc. SO_4H_2 with an intense greenish-yellow colour, whereas the solution in alcohol is colourless; the formation of an alcoholate (with 2HOEt) appears in the latter case to hinder the tautomeric change. This alcoholate can be dissociated by adding benzene to the colourless alcoholic solution when it turns yellow (Hantzsch a. Herrmann, *B.* 21, 1757).

CHLORO-QUINONE-CHLORIMIDE



$C_6H_3Cl\left\langle\begin{matrix}NCl\\ |\\ O\end{matrix}\right.$ $\left[2\,{}^{4}_{1}\right]$. Formed by adding bleaching powder to a solution of the hydro-chloride of chloro-*p*-amido-phenol at 0° (Kollrepp, *A.* 234, 16). Yellow needles (from alcohol or HOAc).

Di-chloro quinone-chlorimide

$C_6H_2Cl_2\left\langle\begin{matrix}NCl\\ |\\ O\end{matrix}\right.$ [6:2:$\frac{4}{1}$]. [67°]. From di-chloro-*p*-amido-phenol hydrochloride by treatment in the cold with bleaching powder (Kollrepp, *A.* 234, 19). Yellow needles; sol. alcohol; decomposes at 170°.

Di-chloro-quinone di-chlorimide

$C_6H_4\left\langle\begin{matrix}NCl\\ |\\ NCl\end{matrix}\right.$. Prepared by the action of chloride of lime on an acid solution of *p*-phenylene-diamine (Krause, *B.* 12, 47). White needles. Insol. cold water, sol. hot water, alcohol ether, C_6H_6 &c. Neutral body. On reduction it gives *p*-phenylene-diamine. By boiling with HCl it gives tetrachlorophenylene diamine. Bromine in acetic acid solution converts it into di-chloro-di-bromo-quinone.

Tri-chloro-quinone chlorimide

$C_6HCl_3\left\langle\begin{matrix}O\\ NCl\end{matrix}\right\rangle$. [118°].

Preparation.—By stirring a slightly acid solution of tri-chloro-*p*-amido-phenol (*q. v.*) with a solution of bleaching powder (Schmitt a. Andresen, *J. pr.* [2] 23, 438; 28, 427).

Properties.—Long yellowish needles, with rough ends. V. sol. hot alcohol, ether and benzene, less sol. cold water. When melted it forms a light-brown liquid, which boils at 185° with decomposition.

Reactions.—1. *Aniline* (3 equivalents) forms di-chloro-quinone dianilide:

$$C_6Cl_3H\left\langle\begin{matrix}O\\ NCl\end{matrix}\right\rangle + 3PhNH_2 + H_2O$$

$$= C_6Cl_2(NPhH)_2\left\langle\begin{matrix}O\\ O\end{matrix}\right\rangle + PhNH_2,HCl + NH_4Cl.$$

But when excess of aniline (5 mols.) is added to saturated alcoholic solution of the chloro-imide at 60° a violent reaction occurs, and the crystals which ultimately separate contain another body also. This is *di-phenyl-di-amido-chloro-quinone-chloro-phenyl-imide*, $C_6Cl(NPhH)_2H\left\langle\begin{matrix}NPh\\ O\end{matrix}\right\rangle$, [195°]. It forms long elastic needles (from alcohol). It is sol. ether, benzene, glacial acetic acid and CS_2. (*a*) Nitrous acid passed into its alcoholic solution produces an unstable nitroso-derivative. (*b*) It is not affected by boiling aqueous potash, but is converted by alcoholic potash into glittering red needles of $C_6Cl(NPhH)_2H(ONa)(NPhNa)$. But this compound is so unstable that alcohol reconverts it into the original body with simultaneous formation of NaOEt. (*c*) Fuming HCl mixed with alcohol reacts thus:

$$C_6Cl(NPhH)_2H\left\langle\begin{matrix}NPh\\ O\end{matrix}\right\rangle + H_2O + HCl$$

$$= C_6Cl(NPhH)_2H\left\langle\begin{matrix}O\\ O\end{matrix}\right\rangle + PhNH_2,HCl$$

(Andresen, *J. pr.* [2] 28, 427).—2. The ethyl derivative of *o*-amido-phenol ($C_6H_4(OEt)NH_2$) acts upon tri-chloro-quinone-chlorimide in a similar way, forming di-ethoxy-di-phenyl-di-chloro-quinone: $C_6Cl_2(NH.C_6H_4.OEt)_2O_2$. This body melts about [200°], crystallises from alcohol in glittering brown prisms, and is thrown down as a grass-green pp. when water is added to its alcoholic solution. It is not dissolved by alkalis, but forms a deep-blue solution with H_2SO_4.—3. *Di-methyl-aniline* in warm alcoholic solution acts thus:  $C_6Cl_3H\left\langle\begin{matrix}O\\ |\\ NCl\end{matrix}\right. + 2PhNMe_2 =$

$C_6Cl_3H\left\langle\begin{matrix}O\\ |\\ N.C_6H_4.NMe_2\end{matrix}\right. + C_6H_5NMe_2,HCl.$ Tri-chloro-quinone-di-methyl-amido-phenyl-imide is almost insoluble in water. It crystallises from alcohol in golden-green needles which have a blue streak (when scratched) and are very tough. It is v. sol. ether, benzene, and chloroform. It is reduced by SO_2 to di-methyl-amido-phenyl-tri-chloro-phenol, $C_6Cl_3H(OH).NH.C_6H_4NMe_2$. This latter is insoluble in water, readily soluble in ether, benzene and chloroform. Recrystallised from alcohol, it melts at [139°], but its alcoholic solution is readily oxidised by the air to the preceding imide. *Salt.*—B'HCl. The *sulphonic acid* of this base $C_6Cl_3(SO_3H)(OH).NH.C_6H_4NMe_2$ is formed along with the base itself by the action of SO_2 on tri-chloro-quinone-di-methyl-amido-phenyl-imide. It crystallises in pearly plates when HCl is added to its solution in NH_3. It is insoluble in water, alcohol, ether and benzene. $BaCl_2$ added to a solution of the acid in an alkali gives a pp. which may be recrystallised from hot water (Schmitt a. Andresen, *J. pr.* 132, 426).—4. Aqueous HCl acts upon tri-chloro-quinone-chloro-imide as follows:

$$C_6Cl_3H\left\langle\begin{matrix}NCl\\ O\end{matrix}\right\rangle + H_2O + 2HCl$$

$$= C_6Cl_3H\left\langle\begin{matrix}O\\ O\end{matrix}\right\rangle + NH_4Cl + Cl_2.$$

HBr acts similarly (Andresen, *J. pr.* [2] 28, 435).

Di-chloro-quinone-di-chlorimide

$C_6H_2Cl_2\left\langle\begin{matrix}NCl\\ |\\ NCl\end{matrix}\right.$ [5:2:4:1]. [135°]. Formed by treatment of a dilute HCl solution of di-chloro-*p*-phenylene diamine [164°] with chloride of lime (Möhlau, *B.* 19, 2011). Colourless prisms (from ether). Sublimable.

CHLORO-RESORCIN $C_6H_3Cl(OH)_2$. [89°]. (256°).

Preparation.—Sulphuryl chloride (1¼ pts.) is added gradually to a solution of resorcin (1 pt.) in dry ether (3 pts.). $C_6H_4(OH)_2 + SO_2Cl_2 = HCl + SO_2 + C_6H_3Cl(OH)_2$.

Properties.—Sol. water, alcohol, ether, benzene, and CS_2. Crystallises with difficulty. Its aqueous solution is feebly acid to litmus. Ammonia turns its aqueous solution first yellow, then green; acids decolourise this liquid. Fe_2Cl_6 gives a bluish-violet colour. Ammoniacal silver solution is reduced on boiling (G. Reinhard, *J. pr.* 125, 322). *Bromine* gives chloro-di-bromo-resorcin (*q. v.*).

Benzoyl derivative $C_6H_3Cl(OBz)_2$. [98°]. Hexagonal crystals (from alcohol). Insol. water.

Di-methyl ether $C_6H_3Cl(OMe)_2$. [118°]. From di-methyl resorcin in HOAc and Cl (Hönig, *B.* 11, 1039). Long needles (from alcohol). Insol. cold HOAc, v. sol. ether.

Di-chloro-resorcin $C_6H_2Cl_2(OH)_2$. [77°]. (249°). Formed by stirring, and finally melting, a mixture of sulphuryl chloride (2½ pts.) with resorcin (1 pt.). Purified by sublimation. The yield is 80 p.c. (G. Reinhard, *J. pr.* [2] 17, 328).

Properties.—V. sol. water, alcohol, ether, benzene, and CS_2. Aqueous solutions are feebly acid to litmus, reduce boiling ammoniacal silver nitrate, and give a bluish-red colour with Fe_2Cl_6.

Reactions.—1. With *bromine-water* it gives di-chloro-bromo-resorcin (*q. v.*).—2. With $ClSO_3H$ it forms a crystalline insoluble powder $C_{12}H_6Cl_4S_2O_9$, probably the anhydride of di-chloro-resorcin sulphonic acid $(C_6HCl_2(SO_3H)OH)_2O$.

Benzoyl derivative $C_6HCl_2(OBz)_2$ [127°].

Di-methyl ether $C_6H_2Cl_2(OMe)_2$. From di-methyl-resorcin in HOAc by Cl (Hönig, *B.* 11, 1039). Oil; decomposed at 140°.

Sulphonic acid $C_6HCl_2(OH)_2SO_3H$. A white powder, sol. water and alcohol. Formed by dissolving its anhydride (see above) in K_2CO_3, acidifying, evaporating, and extracting with alcohol. *Salt.*—BaA'_2.

Tri-chloro-resorcin $C_6HCl_3(OH)_2$. [83°] and [78°].

Preparations.—1. By digesting resorcin with sulphuryl chloride (6 pts.) for 3 hours at 100°. Crystallised from water. The yield is 30 p.c.—2. Resorcin (20 g.) dissolved in water (80 g.) is kept cool and treated with chlorine gas until the red colour, which first appears, is nearly gone. The liquid is heated to 70°, filtered from resin and allowed to deposit crystals.—3. By chlorinating a solution of resorcin (100 g.) in HOAc (250 g.) (Benedikt, *M.* 4, 224).

Properties.—Silky needles, sl. sol. cold water, v. sol. hot water, alcohol, and ether. When purified by sublimation it is yellow and melts at [73°]. Its solutions resemble those of chloro-resorcin in behaviour towards litmus and $AgNO_3$. With Fe_2Cl_6 it gives a wine-red colour on warming (Reinhard, *J. pr.* [2] 17, 336). Oxidised by K_3FeCy_6 to $C_6H_2Cl_2O_2$ [60°] (Stenhouse a. Groves, *B.* 13, 1307).

Benzoyl derivative $C_6HCl_3(OBz)_2$. [133°]. Glittering prisms (from alcohol).

Tri-chloro-resorcin $C_6HCl_3(OH)_2$. [69°]. Formed by the action of $KHSO_3$ on penta-chloro-resorcin (Claassen, *B.* 11, 1441). White needles. V. sol. alcohol, ether, and hot water. May be identical with the preceding.

Tetra-chloro-resorcin. *Di-propyl ether* $C_6Cl_4(OC_3H_7)_2$. From di-propyl-resorcin and Cl (Kariof, *B.* 13, 1678). Liquid; decomposed at 100°. Sol. alcohol and HOAc; sl. sol. water.

Penta-chloro-resorcin $C_6Cl_4(OH)(OCl)$ or $C_6Cl_3(Cl_2)O(OH)$. [92·5°]. Formed by adding alternately in small portions $KClO_3$ (5 pts.) and a solution of resorcin (2 pts.) in HCl (8 pts.) to cooled HCl (40 pts. of S.G. 1·17) (Stenhouse, *Pr.* 20, 78). Plates or flat prisms (from CS_2). V. sol. CS_2, and benzene, v. e. sol. alcohol and ether. Changes in the air into a modification melting at 65° (Liebermann a. Dittler, *A.* 169, 265). Hot water effects the same change.

Reactions.—1. Dissolves in a cold solution of potassium bisulphite with evolution of heat and formation of tri-chloro-resorcin [69°] (Claassen, *B.* 11, 1441). HI appears also to form tri-chloro-resorcin (Stenhouse, *C. N.* 28, 230).—2. Unlike penta-bromo-resorcin, it is not affected by aldehyde and formic acid.

CHLORO-RETENE *v.* Retene.

CHLORO-ROSANILINE *v.* Di-chloro-tri-amido-tri-phenyl-carbinol.

CHLORO-SALICIN *v.* Salicin.

CHLORO-SALICYLIC ACID *v.* Chloro-*o*-oxy-benzoic acid.

CHLORO-SALICYLOL *v.* Chloro-*o*-oxy-benzoic aldehyde.

CHLORO-SALIGENIN *v.* Chloro-oxy-benzyl alcohol.

PER-CHLORO-SEBACIC ACID $C_{10}Cl_{16}H_2O_4$.

Per-chloro-butyl ether $C_{10}Cl_{16}(C_4Cl_9)_2O_4$. [172°]. (200°). From butyl sebacate and Cl in sunshine (Gehring, *C. R.* 104, 1624). Hexagonal prisms.

Per-chloro-isoamyl ether $C_{10}Cl_{16}(C_5Cl_{11})_2O_4$. [179°]. From isoamyl sebacate and Cl in sunshine (G.). Tough trimetric prisms (by sublimation); volatile with steam. Insol. water, sl. sol. alcohol, v. sol. ether, benzene, chloroform, and ligroin.

CHLORO-STEARIC ACID $C_{18}H_{35}ClO_2$. From stearic acid and Cl at 100° (Hardwick, *C. J.* 2, 232).

CHLORO-STILBENE *v.* Chloro-di-phenyl-ethylene.

CHLORO-STRYCHNINE *v.* Strychnine.

(ω)-CHLORO-STYRENE $C_6H_5.CH:CHCl$. (196°) at 716 mm.

Formation.—1. By distilling styrene dichloride $C_6H_5.CHCl.CH_2Cl$ either alone or over CaO (Byth a. Hofmann, *A.* 53, 310).—2. By heating $C_6H_5.CH_2.CHCl_2$ with alcoholic KOH at 120° (Forrer, *B.* 17, 983).

Properties.—Liquid, with pungent odour. Conc. alcoholic KOH followed by distillation with water gives phenyl-acetic aldehyde. KCy gives the nitrile of phenyl-succinic acid (Rügheimer, *B.* 14, 428).

(α)-Chloro-styrene $C_6H_5.CCl:CH_2$. (199°). S.G. ^{23} 1·112.

Formation.—1. By treating cinnamic acid with KOCl or with HCl and potassium chlorate (Stenhouse, *A.* 55, 1; 57, 79).—2. By heating $C_6H_5.CHCl.CH(OH).CO_2H$ with water at 210° (Glaser, *A.* 154, 166).—3. From $C_6H_5.CCl_2.CH_3$ and alcoholic KOH (Friedel, *C. R.* 67, 1192; Erlenmeyer, *B.* 12, 1609).—4. By neutralising a solution of $C_6H_5.CHCl.CHCl.CO_2H$ (Erlenmeyer, *B.* 14, 1867).

Properties.—Liquid, with the odour of hyacinths. Does not so readily give up its Cl as the preceding. But by heating with water acetophenone may be formed (Erlenmeyer, *B.* 14, 323).

ωα-Di-chloro-styrene $C_6H_5.CCl:CHCl$. (221°). From $C_6H_5.CO.CH_2Cl$ and PCl_5 (Dyckerhoff, *B.* 10, 120, 533).

CHLORO-SUBERANE CARBOXYLIC ACID $C_7H_{12}Cl.CO_2H$. From the corresponding oxy-acid and HCl. Oil; sol. alcohol and ether. KOH gives suberene carboxylic acid $C_8H_{12}O_2$ (Dale a. Schorlemmer, *C. J.* 39, 539).

CHLORO-SUBERIC ACID $C_8H_{13}ClO_4$. From suberic acid and Cl (Bauer a. Gröger, *M.* 1, 510; 4, 341). Syrup; sol. water, v. e. sol. ether.

CHLORO-SUBERONIC ACID $C_8H_{13}ClO_2$. From oxy-suberic acid and conc. HCl at 180° (Spiegel, *A.* 211, 119). Oil; v. sol. alcohol and ether. Converted by sodium amalgam into suberonic acid. Boiling NaOHAq forms $C_8H_{12}O_3$.

CHLORO-SUCCINIC ACID

$CO_2H.CH_2.CHCl.CO_2H$. [152°]. Prepared by heating fumaric acid with a solution of HCl in glacial acetic acid (Anschütz a. Bennert, *B.* 15, 642). Crystalline solid. Sol. water and acetic acid, sl. sol. chloroform.

Anhydride 
$$\begin{array}{l} CHCl.CO \\ | \qquad\quad >O \\ CH_2\,.\,CO \end{array}$$

[41°]. (130° at 15 mm.). Prepared by heating the acid with acetyl chloride. Formed as a by-product, when maleïc anhydride is produced by heating fumaric acid with AcCl for 8 hrs. at 140° (Perkin, *C. J.* 41, 269). Crystalline solid Sol. chloroform. On heating it decomposes into maleïc anhydride and HCl.

Di-chloro-succinic acid $C_2H_2Cl_2(CO_2H)_2$. Two acids of this constitution are formed by the union of Cl with fumaric and maleic acids respectively. They differ in melting-point and solubility (Petrieff, *Bl.* [2] 41, 309).

Tetra-chloro-succinic acid. *Per-chloro-ethyl ether* $C_2Cl_4(CO_2C_2Cl_5)_2$. [116°-120°]. From succinic ether and Cl in sunshine (Cahours, *A.* 47, 294). Small needles. Decomposed by solution in alcohol, and by alcoholic KOH, tri-chloro-acetic acid being among the products. Ammonia forms tri-chloro-acetamide and other products (*cf.* Malaguti, *A. Ch.* [3] 16, 72).

CHLORO-SULPHO-ACETIC ACID

$CHCl(SO_3H).CO_2H$. From chloro-acetic acid and $ClSO_3H$. Formed also by oxidation of thio-hydantoïn by $KClO_3$ and HCl (Andreasch, *M.* 7, 159).—BaA″aq: S. 2·5 at 17°.—K_2A'' $1\frac{1}{2}$aq.—$(NH_4)_2A''$: needles, v. sol. water.—Ag_2A'' $\frac{1}{2}$aq: prisms.

CHLORO-SULPHO-BENZOIC ACID

$C_7H_5ClSO_5$ *i.e.* $C_6H_3Cl(SO_3H)(CO_2H)$ [1:3or5:2]. From *o*-chloro-toluene sulphonic acid by oxidation with chromic mixture (Hubner a. Majert, *B.* 6, 792).—KHA″aq.—BaA″2aq.—PbA″2aq.

Chloro-sulpho-benzoic acid $C_6H_3Cl(SO_3H)(CO_2H)$ [1:3?:5]. From *m*-chloro-benzoic acid and SO_3 (Otto, *A.* 123, 216). Needles (containing *x*aq); v. sol. water, alcohol, and ether. With PCl_5 it gives di-chloro-benzoic chloride.—KHA″ $1\frac{1}{2}$aq.—K_2A''3aq.—BaA″2aq.—$BaH_2A''_2$4aq.—$CaH_2A''_2$8aq.—PbA″3aq.

Amide $C_6H_3Cl(SO_2NH_2)(CONH_2)$: crystals.

Chloro-sulpho-benzoic acid $C_6H_3Cl(SO_3H)(CO_2H)$ [1:2:4]. From *p*-chloro-benzoic acid and fuming H_2SO_4 at 130° (Cöllen, *A.* 191, 29; *B.* 9, 758, 1248). Long needles (from water). Sl. sol. alcohol and ether.

Salts.—NaHA″2aq.—Ag_2A''aq.—BaA″3aq. MgA″6aq.—ZnA″4aq.—CuA″6aq.—PbA″4aq.

Chloride $C_6H_3Cl(SO_2Cl)CO_2H$. [140°-150°]. Needles (from ether).

(α)-CHLORO-TEREBIC ACID $C_7H_9ClO_4$ *i.e.* $(CH_3)_2\underline{C.CH(CO_2H).CH_2.CO.O}$? (Frost, *A.* 226, 363). [191°]. From terebic acid (1 mol.) and PCl_5 (3 mols.) (Williams, *B.* 6, 1097; Roser, *A.* 220, 265). The (β)-isomeride is formed at the same time. V. sol. hot water, alcohol, or ether. At 150° it begins to sublime.

Reaction.—1. Splits off HCl, forming terebilenic acid $C_7H_8O_4$ (*q.v.*), when heated to 200°, or with water at 140°, or by boiling with NaOEt (W. Roser, *A.* 220, 261).—2. Boiled with water and $CaCO_3$ it forms oxy-terebic acid.—3. With PCl_5 at 130°-140° forms chloro-terebilenic acid.

Salts.—CaA″2aq.—AgHA″.—PbA″3aq.

(β)-Chloro-terebic acid $C_7H_9ClO_4$ *i.e.* $(CH_3)_2\underline{C.CBr(CO_2H).CH_2.CO.O}$(?) [168°]. Formed by the action of Cl on teraconic acid in presence of water in the cold. Colourless, transparent, trimetric crystals; $a:b:c = 0·9827:1:0·7137$. Easily decomposed by boiling water into HCl and terebilic acid: $C_7H_8O_4$ (Frost, *A.* 226, 363).

CHLORO-TEREBILENIC ACID $C_7H_7ClO_4$ *i.e.* $Me_2\underline{C.C(CO_2H):CCl.CO.O}$ (?) [200°-203°]. From chloro-terebic acid [191°] and PCl_5 at 140° (W. Roser, *A.* 220, 265). Small prisms. V. sol. water. Not affected by boiling water, hardly even by boiling with moist Ag_2O.

Salts.—$CaA'_2$2aq.—AgA′.

CHLORO-TEREPHTHALIC ACID

$C_6H_3Cl(CO_2H)_2$ [1:2:5]. [123°]. Formed by oxidising $C_6H_3Cl(C_2H_5)_2$ with bichromate mixture and separating the two isomeric acids formed by boiling water. White crystals; insol. boiling aq; sol. ammonia, reppd. by HCl as a curdy pp. resembling AgCl; sl. sol. warm alcohol; sol. benzene, $CHCl_3$, CS_2 and ether; sol. hot ligroin. Sublimes at 100°. It distils without forming any anhydride (Istrati, *A. Ch.* [6] 6, 418).

Chloro-terephthalic acid $C_6H_3Cl(CO_2H)_2$ [2:1:4]. [above 300°]. Obtained by the action of cuprous chloride upon the diazo- compound from amido-terephthalic acid. Colourless crystals. V. sol. alcohol and ether, sl. sol. hot water.—Ag_2A'': white pp.

Di-methyl ether $A''Me_2$: [60°]; silky plates; v. sol. alcohol and ether, sl. sol. water.

Chloride $C_6H_3Cl(COCl)_2$: (c. 300°); crystalline.

Amide $C_6H_3Cl(CONH_2)_2$: [above 300°]; white crystalline crusts; sl. sol. water (Ahrens, *B.* 19, 1638).

Di-chloro-terephthalic acid $C_6H_2Cl_2(CO_2H)_2$ [5:2:4:1]. From the dihydride and dilute HNO_3. Hair-like needles; does not melt at 300°.

Methyl ether Me_2A''. [132°].

Dihydride $C_6H_4Cl_2(CO_2H)_2$. [c. 274°]. From succinyl-succinic ether (1 mol.) and PCl_5 (4 mols.) (Levy a. Andreocci, *B.* 21, 1463). Scales (from water). V. sol. alcohol and ether, sl. sol. benzene, $CHCl_3$, and CS_2.—BaA″3aq.—CaA″4aq.—NaHA″3aq.—Ag_2A''.—Me_2A''. [110°].—Et_2A''. [71°].

TRI-CHLORO-DI-THIËNYL-ETHANE

$CCl_3.CH(C_4H_3S)_2$. [76°]. Obtained by adding H_2SO_4 to a mixture of thiophene and chloral dissolved in acetic acid (Peter, *B.* 17, 1341). Colourless tables. V. sol. ether, petroleum-ether, CS_2, and hot alcohol, sl. sol. cold alcohol. Heated with isatin and H_2SO_4 it gives a violet-red colour.

DI-CHLORO-DI-THIËNYL-ETHYLENE

$CCl_2:C(C_4H_3S)_2$. Formed by boiling tri-chloro-di-thiënyl-ethane with alcoholic KOH, or, better, KCN (Peter, *B.* 17, 1343). Colourless oil. Volatile with steam. With isatin and H_2SO_4 it gives a violet-blue colour.

CHLORO-THIËNYL METHYL KETONE

$C_4SH_2Cl.CO.CH_3$. *Chloro-acetothiënone.* [52°].

Formed by the action of acetyl chloride upon chloro-thiophene in presence of Al_2Cl_6. Large colourless tables (from alcohol or ether). Very volatile with steam. By alkaline $KMnO_4$ it is oxidised to chloro-thiophene-carboxylic acid [140°].

Phenyl-hydrazide $C_4SH_2Cl.C(N_2HPh).CH_3$: [108°]; yellow tables; sol. hot alcohol (Gattermann a. Römer, *B.* 19, 693).

Isomeride: THIENYL CHLORO-METHYL KETONE.

CHLORO-THIO-ACETIC ACID $CH_2Cl.CS.OH$.

Ethyl ether A′Et. (167°). Prepared by heating chloro-acetic ether with P_2S_5 at 140° (Meyer, *B.* 14, 1508). Liquid.

Di-chloro-thio-acetic acid $CHCl_2.CS.OH$.

Ethyl ether A′Et. (178°). Prepared by heating di-chloro-acetic ether with P_2S_5 at 180° (Meyer, *B.* 14, 1507). Oil.

***p*-CHLORO-DI-THIO-BENZOIC ACID** $C_6H_4Cl.CS_2H$. From $C_6H_4Cl.CCl_3$ and alcoholic potassium sulphide (Engelhardt a. Latschinoff, *Z.* 1868, 459).—HgA'_2: greenish-golden laminæ (from alcohol).—PbA'_2: brick-red pp.

CHLORO-THIO-CARBONYL CHLORIDE *v.* THIO-CARBONYL CHLORIDE, vol. i. p. 695. See also PER-CHLORO-METHYL MERCAPTAN.

CHLORO-THIO-CARBONYL SULPHUR-CHLORIDE $CSCl.SCl$. (140° *in vacuo*). Oil. Formed by heating $CSCl_2$ with sulphur at 130°–150°. By chlorine it is converted into per-chloro-methyl-mercaptan and sulphur chloride, as follows: $2CSCl.SCl + 3Cl_2 = 2CCl_3.SCl + S_2Cl_2$. Heated with sulphur at about 160° it yields CS_2 and S_2Cl_2 (Klason, *B.* 20, 2381).

CHLORO-THIO-FORMIC ACID $Cl.CO.S.H$.

Amyl ether $Cl.CO.S.C_5H_{11}$. (193°). S.G. $_{17\cdot5}$ 1·078. μ_D 1·4766.

Preparation.—By saturating amyl mercaptan with $COCl_2$, and, after a few days, fractionally distilling the product (H. Schöne, *J. pr.* [2] 32, 243).

Properties.—A liquid of unpleasant odour, between that of amyl alcohol and that of mercaptan. It does not fume in the air.

Reactions.—1. Converted by NaSMe into $CO(SC_5H_{11})(SMe)$.—2. Converted by NaOEt into $CO(SC_5H_{11})(OEt)$.—3. Dry NH_3 forms $CO(SC_5H_{11})(NH_2)$.—4. With *aniline* it forms $CO(S.C_5H_{11})NPhH$ (*v.* PHENYL THIO-CARBAMIC ACID). — 5. It reacts with urea forming $NH_2.CO.NH.CO.SC_5H_{11}$ (*v.* THIO-ALLOPHANIC ACID). 6. With phenyl-thio-urea it gives rise to $NPhH.CS.NH.CO.S.C_5H_{11}$ (*v.* PHENYL-DI-THIO-ALLOPHANIC ACID).—7. With diphenyl-thio-urea it forms $NPhH.CS.NPh.CO.S.C_5H_{11}$ (*v.* DI-PHENYL-DI-THIO-ALLOPHANIC ACID).

Ethyl ether $Cl.CO.SEt$. (136°). S.G. ^{15} 1·84. From $COCl_2$ and mercaptan (Salomon, *J. pr.* [2] 7, 252). Oil. Converted by NH_3 into $NH_2.CO.SEt$.

Chloro-thio-formic acid $Cl.CS.OH$.

Ethyl ether $Cl.CS.OEt$. (136°). Formed n small quantity by the action of alcohol on $CSCl_2$ (Klason, *B.* 20, 2384). Converted by NH_3 nto xanthogenamide $NH_2.CS.OEt$.

Chloro-di-thio-formic ether $Cl.CS.SEt$. (100°) n *vacuo*. S.G. ^{15} 1·141. From $CSCl_2$ and EtSH. Yellow oil, smelling like garlic (K.).

CHLORO-THIOPHENE C_4H_3ClS. (130°). Obtained, together with di-chloro-thiophene, by passing chlorine into crude thiophene (Weitz, *B.* 17, 794). Strongly refractive colourless oil. Gives the indophenine reaction.

Di-chloro-thiophene $C_4H_2Cl_2S$. (170°). Obtained, together with the mono-chloro-thiophene, by passing chlorine into crude thiophene (Weitz, *B.* 17, 794). Heavy oil. Gives the indophenine reaction.

Tri-chloro-thiophene C_4SHCl_3. (206° uncor.). A by-product in the preparation of tetra-chloro-thiophene (Rosenberg, *B.* 19, 650). Heavy oil. Gives the indophenine reaction.

Tetra-chloro-thiophene C_4Cl_4S. [36°]. (245°). Obtained by passing chlorine into di-bromo-thiophene (Weitz, *B.* 17, 792). Long white needles.

CHLORO-THIOPHENE-CARBOXYLIC ACID $C_4SH_2Cl(CO_2H)$. *Chloro-thiophenic acid.* [140°]. Formed by oxidation of chloro-thiënyl methyl ketone with alkaline $KMnO_4$. Colourless needles (from hot water). Sublimes in spikes. Sl. sol. water (Gattermann a. Römer, *B.* 19, 694).

TETRA-CHLORO-THIOPHENE TETRA-CHLORIDE C_4Cl_8S. [215°].

Preparation.—Chlorine is passed into a solution of iodo-thiophene in $CHCl_3$. The liquid is shaken with aqueous NaOH, the chloroform evaporated, the residue extracted with alcohol and crystallised from chloroform.

Properties.—Thick prisms, resembling urea. A pungent, but not unpleasant odour. V. sol. chloroform, ether, benzene, CS_2, glacial acetic acid, and alcohol (C. Willgerodt, *J. pr.* [2] 33, 150).

TRI-CHLORO-THIOPHENE-SULPHONIC ACID $C_4SCl_3.SO_3H$. Formed by boiling the anhydride with water or alkalis.

Anhydride $(C_4SCl_3.SO_2)_2O$. Formed by the action of pyrosulphuric acid upon tri-chloro-thiophene. White glistening crystals. Sol. benzene, nearly insol. water, alcohol, and ether (Rosenberg, *B.* 19, 651).

CHLORO-THYMOHYDROQUINONE *v.* CHLORO-HYDRO-THYMOQUINONE.

TRI-CHLORO-THYMOL $C_{10}H_{11}Cl_3O$ *i.e.* $C_6Cl_3(C_3H_7)(CH_3)(OH)$. [61°]. From thymol and Cl in daylight (Lallemand, *A. Ch.* [3] 49, 148). Lemon-yellow monoclinic prisms. Decomposes at about 180°. Conc. H_2SO_4 at 100° converts it into a crystalline body [45°] (250°).

Penta-chloro-thymol $C_{10}H_9Cl_5O$. [98°]. From thymol and Cl in bright daylight (L.). Hard crystals. At 200° it splits up into propylene, HCl, and tri-chloro-cresol.

***o*-CHLORO-THYMOQUINONE** $C_6HMePrClO_2$ [1:4:2:3:6]. Formed by oxidation of the corresponding hydroquinone with Fe_2Cl_6. Yellowish mobile oil. Easily volatile with steam. V. sol. alcohol and ether (Schniter, *B.* 20, 1317).

***m*-Chloro-thymoquinone** $C_6HMePrClO_2$ [1:4:5:3:6]. Formed from *m*-bromo-thymoquinone by treatment with chlorine, the Br being replaced by Cl. Oil (Schniter, *B.* 20, 1319).

Di-chloro-thymoquinone

$C_6Cl_2MePr<^{O}_{O}$

[99°]. The ethereal extract from the product of the action of HCl on thymo-quinone-chlorimide (*q. v.*) is evaporated and distilled with steam. It crystallises in the receiver.

Properties.—Trimetric tablets (from alcohol).

Turned brown by light. Not reduced by SO_2 Andresen, *J. pr.* [2] 23, 176).

CHLORO - THYMO - QUINONE CHLORIMIDE $C_6HClMePr{<}\begin{matrix}O\\NCl\end{matrix}$. An oil prepared by adding a solution of bleaching powder to the hydrochloride of chloro-amido-thymol, exactly as described under thymo-quinone-chlorimide.

Reactions.—Conc. HCl acts upon it exactly as it does upon thymo-quinone-chlor-imide, orming chloro-amido-thymol, chloro-thymo-uinone, and di-chlorothymoquinone (*q. v.*) (Anresen, *J. pr.* 131, 187).

CHLORO-TIGLIC ACID $C_4H_6Cl.CO_2H$. [69°]. 210°). Formed by the action of alcoholic KOH upon (*a*)-di-chloro-di-methyl-succinic acid $CO_2H.CClMe.CClMe.CO_2H$, or by heating the silver-salt with water (Otto a. Beckurts, *B.* 18, 53). Formed also by treating methyl-aceto-acetic ether with PCl_5 followed by water (Rücker, *A.* 201, 54; Demarçay, *B.* 10, 1177). Glistening plates, or small needles. Sublimable and easily volatile with steam. V. sol. alcohol and ether, l. sol. cold water. Decomposed by aqueous KOH at 150° into CO_2 and methyl ethyl ketone Friedrich, *A.* 219, 859).—BaA'_2.—ZnA'_2 1½aq.—AgA′.

Ethyl ether EtA′. (174°) (R.); (179°) (D.). Oil.

DI-CHLORO-TOLUCARBOSTYRIL *v.* DI-HLORO-OXY-METHYL-QUINOLINE.

***o*-CHLORO-TOLUENE** C_7H_7Cl *i.e.* $C_6H_4(CH_3)Cl$ [1:2]. Mol. w. 126½. (154° uncor.).

Formation.—1. In small quantity, together with the *p*-modification, by chlorinating toluene in presence of iodine (Hübner a. Majert, *B.* 6, 90).—2. By running a solution of $NaNO_2$ into a hot solution of *o*-toluidine, and Cu_2Cl_2 in dilute HCl (Sandmeyer, *B.* 17, 2651; *cf.* Beilstein a. Kuhlberg, *A.* 156, 79).—3. By heating *o*-diazo-oluene with a large excess of strong HCl; the yield is 40 p.c. of the theoretical (Gasiorowski a. Wayss, *B.* 18, 1939).—4. By decomposing with uperheated steam the sulphonic acid obtained by acting on commercial mono-chloro-toluene with sulphuric acid. The *o*- compound is much more easily sulphonated than the *p*- compound, and the Ca and Na salts of the resulting acid are much less soluble. The separation is, however, not a perfect one (Seelig, *A.* 237, 151, 155).

Properties.—Liquid. Converted by oxidation nto *o*-chloro-benzoic acid (Wroblewsky, *Z.* [2] 460). On nitration it gives a mixture of $C_6H_4(CH_3)Cl(NO_2)$ [1:2:5] and [1:2:6] (Hönig, *B.* 20, 2417).

***m*-Chloro-toluene** $C_6H_4(CH_3)Cl$ [1:3]. (156°). From *m*-toluidine by displacement of NH_2 by Cl through the diazo- reaction. Formed also by eliminating NH_2 from chloro-*p*-toluidine (Wroblewsky, *A.* 168, 199). Oxidised by CrO_3 to *m*-chloro-benzoic acid.

***p*-Chloro-toluene** $C_6H_4(CH_3)Cl$ [1:4]. [6·5°]. (160°). S.V. 134·91 (R. Schiff, *A.* 220, 99). S.G. ^{14} 1·080.

Formation.—1. By chlorinating toluene in presence of iodine, $MoCl_5$, or other carriers (Deville, *A. Ch.* [3] 3, 178; Beilstein a. Geitner, *A.* 139, 331; *Bl.* [2] 1, 251; Aronheim a. Dietrich, *B.* 8, 1402).—2. By running a solution of $NaNO_2$ into a hot solution of *p*-toluidine and Cu_2Cl_2 in dilute HCl (Sandmeyer, *B.* 17, 2651; *cf.* Hübner a. Majert, *B.* 6, 794).—3. By heating *p*-diazo-toluene with a large excess of HCl; the yield is 40 p.c. of the theoretical (Gasiorowski a. Waÿss, *B.* 18, 1939).

Properties.—Liquid. Not attacked by water at 200°, nor by alcoholic NH_3 at 100° or alcoholic Na_2S, NaHS, or NaOEt at 150°. Chromic mixture gives *p*-chloro-benzoic acid. On nitration it gives (4:2:1) chloro-nitro-toluene [38°], and (4:3:1) chloro-nitro-toluene [9°] (Goldschmidt a. Hönig, *B.* 19, 2438).

ω-chloro-toluene *v.* BENZYL CHLORIDE.

(β)-Di-chloro-toluene $C_6H_3(CH_3)Cl_2$[1:2:4]. (197°) (S.). S.G. $\frac{20}{20}$ 1·2460 (L. a. K.). From $C_6H_3MeCl(NO_2)$[1:2:4] *viâ* $C_6H_3MeCl(NH_2)$ (Lellmann a. Klotz, *A.* 231, 314). Formed also by chlorinating *p*-chloro-toluene (Seelig, *A.* 237, 167). Oil. Gives di-chloro-benzoic acid [158°].

Di-chloro-toluene $C_6H_3(CH_3)Cl_2$[1:2:5]. [5°] (194° uncor.) at 745 mm. S.G. $\frac{20}{20}$ 1·2535. From $C_6H_3Me(NH_2)Cl$[1:2:5] by diazo- reaction (Lellmann a. Klotz, *A.* 231, 318). Gives di-chloro-benzoic acid [156°].

Di-chloro-toluene $C_6H_3(CH_3)Cl_2$[1:3:5]. [26°]. (195° uncor.) at 729 mm. Prepared from $C_6H_2Me(NH_2)Cl_2$[1:4:3:5] by diazo- reaction (Lellmann a. Klotz, *A.* 231, 323). Gives di-chloro-benzoic acid [182°].

(α)-Di-chloro-toluene $C_6H_3(CH_3)Cl_2$[1:2:3]. (197°). Formed by the action of chlorine on toluene in presence of ferric chloride or other carriers (Seelig, *A.* 237, 157). Yields a nitro- derivative [51°] or a dinitro- derivative [122°]. On oxidation with alkaline permanganate it gives di-chloro-benzoic acid [166°].

Di-chloro-toluene $C_6H_3(CH_3)Cl_2$ [1:3:4]. (200° uncor.) at 740 mm. S.G. $\frac{20}{20}$ 1·2512.

Formation.—1. From $C_6H_3MeCl(NH_2)$ [1:3:4] by diazo-reaction (Lellmann a. Klotz, *A.* 231, 311). 2. A product of the chlorination of toluene in presence of carriers (Beilstein a. Geitner, *A.* 139, 341; Beilstein a. Kuhlberg, *A.* 150, 313; Aronheim a. Dietrich, *B.* 8, 1401; Neuhof, *Z.* [2] 2, 653; Schultz, *A.* 187, 263).—3. From chloro-*p*-cresol and PCl_5 (Schall a. Dralle, *B.* 17, 2535).

Properties.—Oil. Gives on oxidation di-chloro-benzoic acid [201°].

ω*p*-Di-chloro-toluene [4:1] $C_6H_4Cl.CH_2Cl$. *p-Chloro-benzyl chloride.* [29°]. (213°).

Formation.—1. By chlorinating *p*-chloro-toluene at 160° (Neuhof, *A.* 146, 320; Jackson a. Field, *Am.* 2, 85; *P. Am. A.* 14, 54; *B.* 11, 904). 2. By chlorinating cold benzyl chloride in presence of iodine (N.).

Properties.—Needles or prisms; insol. water, sol. alcohol and ether. Powerfully attacks the mucous membrane. Very volatile. Oxidation gives *p*-chloro-benzoic acid. Boiling water forms *p*-chloro-benzyl alcohol. Boiling aqueous $Pb(NO_3)_2$ gives *p*-chloro-benzoic aldehyde. Alcoholic KCy forms phenyl-acetonitrile.

ωω - Di - chloro - toluene *v.* BENZYLIDENE CHLORIDE.

(α)-Tri-chloro-toluene $C_6H_2(CH_3)Cl_3$ [1:2:4:5]. [82°]. (230°). Is formed, together with the (β)-derivative, by passing chlorine into toluene in presence of Fe_2Cl_6 or other carriers (Limpricht, *A.* 139, 303; Aronheim a. Dietrich, *B.* 8, 1401; Schultz, *A.* 187, 274; Seelig, *A.* 237, 133). Long needles, sol. alcohol. Forms a sulphonic acid, which is decomposed by superheated steam at

160°. Chromic mixture oxidises it to tri-chloro-benzoic acid [168°] (Janasch, *A.* 142, 301).

(β)-Tri-chloro-toluene $C_6H_2(CH_3)Cl_3$ [1:2:3:4]. [41°]. (232°). Is formed together with the (*a*) isomeride by passing chlorine into toluene in presence of Fe_2Cl_6 (Seelig, *A.* 237, 133). Forms a sulphonate, which is decomposed by super-heated steam at about 210°. Gives tri-chloro-benzoic acid [129°].

ω-exo-**Tri-chloro-toluene** $C_6H_3Cl_2.CH_2Cl$. (240°). S.G. 1·44. A product of the chlorination of toluene and of benzyl chloride (Naquet, *A. Suppl.* 2, 248; Kekulé, *K.* 2, 561). Formed also by chlorinating boiling di-chloro-toluene (Beilstein a. Kuhlberg, *A.* 146, 317). Liquid. Alcoholic KOAc gives $C_6H_3Cl_2.CH_2OAc$.

ωωo-**Tri-chloro-toluene** [2:1] $C_6H_4Cl.CHCl_2$. *o-Chloro-benzylidene chloride.* (c. 230°). From salicylic aldehyde and PCl_5 (Henry, *B.* 2, 135; *Z.* [2] 5, 371). Formed also, together with the following, by chlorinating benzylidene chloride in presence of iodine (B. a. K.). Water at 170° converts it into chloro-benzoic aldehyde. Chromic mixture forms *o*-chloro-benzoic acid. Distillation with dry oxalic acid forms *o*-chloro-benzoic aldehyde (Anschütz, *A.* 226, 19).

ωωp-**Tri-chloro-toluene** [4:1] $C_6H_4Cl.CHCl_2$. *p-Chloro-benzylidene chloride.* (234°). Formed as above (B. a. K.). Resembles the preceding in its reactions.

ωωω-**Tri-chloro-toluene** *v.* BENZOTRICHLORIDE.

Tetra-chloro-toluene $C_6HCl_4.CH_3$. [96°] (L.); [91°] (B. a. K.). (276° cor.). Among the products of chlorinating toluene in presence of $SbCl_5$ (Limpricht, *A.* 139, 327). Slender needles (from alcohol).

Tetra-chloro-toluene $C_7H_4Cl_4$. (280°–290°). From di-chloro-toluene tetrachloride and alcoholic KOH (Pieper, *A.* 142, 305).

Tetra-chloro-toluene $C_6H_2Cl_3.CH_2Cl$. *Tri-chloro-benzyl chloride.* (273°). S.G. ^{22} 1·547. From $C_6H_2Cl_3.CH_3$ and Cl at high temperatures (Beilstein a. Kuhlberg, *A.* 150, 286).

Tetra-chloro-toluene $C_6H_3Cl_2.CHCl_2$ [4:3:1]. (*a*)-*Di-chloro-benzylidene chloride.* (257°). S.G. ^{22} 1·518. From Cl and boiling (4,3,1)-di-chloro-toluene (B. a. K.). Water at 220° gives di-chloro-benzoic aldehyde.

Tetra-chloro-toluene $C_6H_3Cl_2.CHCl_2$ [1:3:6]. (β)-*Di-chloro-benzylidene chloride.* (c. 260°) Formed by passing chlorine into (β)-di-chloro-toluene heated at 230° (Seelig, *A.* 237, 167). Is converted into dichlorobenzoic aldehyde on treating with conc. H_2SO_4.

Tetra-chloro-toluene [2:1] $C_6H_4Cl.CCl_3$. *o-Chloro-benzotrichloride.* [30°]. (260°). From *o*-oxy-benzoic acid by distilling with PCl_5 (Kolbe a. Lautemann, *A.* 115, 195). Water at 150° gives *o*-chloro-benzoic acid.

Tetra-chloro-toluene [3:1] $C_6H_4Cl.CCl_3$. *m-Chloro-benzotrichloride.* (235°). From *m*-sulpho-benzoic acid and PCl_5 (Carius a. Kämmerer, *A.* 131, 158).

Tetra-chloro-toluene [4:1] $C_6H_4Cl.CCl_3$. *p-Chloro-benzotrichloride.* (245°).

Formation.—1. From benzotrichloride and Cl in presence of carriers (Beilstein a. Kuhlberg, *A.* 146, 317).—2. From benzoyl chloride and PCl_5 (Limpricht, *A.* 134, 57).—3. From *p*-oxy-benzide  $C_6H_4\left\langle\begin{matrix}O\\|\\CO\end{matrix}\right.$ and PCl_5. The product is freed from $POCl_3$ by distillation, and the residue shaken with dilute NaOH (Klepl, *J. pr.* [2] 28, 204).

Properties.—Oil. Converted by warm conc. H_2SO_4 or by water at 200° into *p*-chloro-benzoic acid.

Penta-chloro-toluene $C_6Cl_5.CH_3$. [218°]. (301°). Formed by chlorinating toluene in presence of iodine (B. a. K.). Needles (from benzene).

Penta-chloro-toluene $C_6HCl_4.CH_2Cl$. *Tetra-chloro-benzyl chloride* (296°). S.G. ^{25} 1·634. From boiling tetra-chloro-toluene and Cl (B. a. K.). Further chlorination gives C_6Cl_6 and CCl_4 (Beilstein a. Kuhlberg, *Z.* [2] 5, 527).

Penta-chloro-toluene $C_6H_2Cl_3.CHCl_2$ [2:4:5:1]. (*a*)-*Tri-chloro-benzylidene chloride.* (281°). S.G. ^{22} 1·607. From Cl and boiling tri-chloro-toluene (B. a. K.). Needles (below 0°). Water at 250° or cold fuming H_2SO_4 gives tri-chloro-benzoic aldehyde.

Penta-chloro-toluene $C_6H_2Cl_3.CHCl_2$ [4:3:2:1]. (β)-*Tri-chloro-benzylidene chloride.* [84°]. (c. 280°). Formed by passing chlorine through boiling (β)-tri-chloro-toluene (Seelig, *A.* 237, 146). Oil solidifying to a crystalline mass. Sol. petroleum ether. Treated with fuming sulphuric acid it forms (β)-tri-chloro-benzoic aldehyde.

Penta-chloro-toluene $C_6H_3Cl_2.CCl_3$. *Di-chloro-benzotrichloride.* (273°). S.G. ^{21} 1·587. From crude di-chloro-toluene and Cl (B. a. K.). Water at 200° gives a mixture of di-chloro-benzoic acids.

Hexa-chloro-toluene $C_7H_2Cl_6$ *i.e.* $C_6Cl_5.CH_2Cl$. *Penta-chloro-benzyl chloride.* [103°]. (326°). From benzyl chloride and Cl in presence of $SbCl_5$. Formed also by chlorinating boiling penta-chloro-toluene (B. a. K.; *cf.* Deville, *A.* 44, 304). Slender needles; sl. sol. alcohol; v. sol. benzene. Alcoholic KOAc at 200° gives $C_6Cl_5.CH_2OH$.

Hexa-chloro-toluene $C_6HCl_4.CHCl_2$. *Tetra-chloro-benzylidene chloride.* (306°). S.G. ^{25} 1·704. From Cl and boiling tetra-chloro-toluene $C_6HCl_4.CH_3$ (B. a. K.). Water at 280° gives tetra-chloro-benzoic aldehyde.

Hexa-chloro-toluene $C_6HCl_3.CCl_3$. *Tri-chloro-benzotrichloride.* [82°]. (308°). From Cl and boiling $C_6HCl_3.CH_3$ (Beilstein a. Kuhlberg, *A.* 150, 305). Slender needles (from alcohol). Water at 260° gives tri-chloro-benzoic acid.

Hepta-chloro-toluene $C_6Cl_5.CHCl_2$. *Penta-chloro-benzylidene chloride.* [110°]. (334°). Formed by chlorinating benzylidene chloride with the aid of carriers (B. a. K.). Flat laminæ (from alcohol). Sl. sol. cold alcohol, v. sol. boiling alcohol. Water at 300° does not act upon it.

Hepta-chloro-toluene $C_6HCl_4.CCl_3$. [104°]. (316°). From Cl and boiling $C_6HCl_4.CH_3$ (B. a. K.). Short needles (from alcohol); m. sol. hot alcohol. Water at 270° gives tetra-chloro-benzoic acid.

CHLORO - TOLUENE - AZOXY - CHLORO - TOLUENE *v.* AZOXY- COMPOUNDS.

DI-CHLORO-TOLUENE TETRACHLORIDE $C_7H_6Cl_6$ *i.e.* $C_6H_3Cl_6.CH_3$. [150°]. From toluene and Cl (Pieper, *A.* 142, 304). Prisms (from CS_2). Alcoholic NaOH at 110° gives di-chloro-benzoic acid [203°] and tetra-chloro-toluene (c. 285°).

***p*-CHLORO-TOLUENE-(β)-SULPHONIC ACID** $C_6H_3MeCl(SO_3H)$ [1:4:2]. From *p*-chloro-toluene and H_2SO_4 (Vogt a. Henninger, *A.* 165, 362). Also from the corresponding *p*-toluidine *o*-sulphonic acid by displacement of NH_2 by Cl (Jenssen, *A.* 172, 289).

Salts.—BaA'_2 $1\frac{1}{2}$aq: S. 1·9 at 16°.—BaA'_2 aq (Hübner a. Majert, *B.* 6, 790). — KA′ aq. — CaA'_2 6aq.—PbA'_2 8aq.—CuA'_2 7aq.

Amide $C_6H_3Cl.Me.SO_2NH_2$ [138°]. From $C_6H_3(NH_2)Me.SO_2NH_2$ by HCl and nitrous acid gas (Heffter, *A.* 221, 209).

p-**Chloro-toluene (α)-sulphonic acid** $C_6H_3MeCl(SO_3H)$ [1:4:3]. Formed, together with the preceding, by sulphonating *p*-chloro-toluene (Vogt a. Henninger, *A. Ch.* [4] 27, 129). Converted by potash-fusion into orcin.

Salts. — KA′ $\frac{1}{2}$aq: laminæ. — NaA′ 5aq. — BaA'_2 2aq: S. 5·71 at 16·5° (V. a. H.).—BaA'_2 $\frac{1}{2}$aq: S. 14 at 14° (Hübner a. Majert, *B.* 6, 790).—BaA'_2 aq (V. a. H.).—BaA'_2 7aq (Engelbrecht, *B.* 7, 796).—CdA'_2 2aq.—PbA'_2 6aq.—CuA'_2 10aq.

o-**Chloro-toluene sulphonic acid** $C_6H_3MeCl(SO_3H)$ [1:2:3or5]. From *o*-chloro-toluene and H_2SO_4 (Hübner a. Majert, *B.* 6, 790). Sodium amalgam gives toluene *m*-sulphonic acid. Oxidation forms chloro-sulpho-benzoic acid.—NH_4A' aq. — KA′ $\frac{1}{2}$aq. — NaA′ $\frac{1}{2}$aq.—BaA'_2 2aq.—CaA'_2 2aq.—PbA'_2 2aq.—CuA'_2 $\frac{1}{2}$aq.

Chloro-toluene sulphonic acid $C_6H_3MeCl(SO_3H)$ [1:2:4]. From the amide and HCl at 150°. **Salts.**—BaA'_2.—KA′.

Chloride $C_6H_3ClMe.SO_2Cl$. Oil.

Amide $C_6H_3MeCl.SO_2NH_2$. [135°]. From $C_6H_3Me(SO_2NH_2).N_2.NH.C_6H_3Me.SO_2NH_2$ and HCl (Paysan, *A.* 221, 212).

p-**Chloro-toluene ω-sulphonic acid** [4:1]$C_6H_4Cl.CH_2.SO_3H$. *Chlorobenzyl sulphonic acid.* [108°] (?). From $C_6H_4Cl.CH_2Cl$ and aqueous K_2SO_3 (Böhler, *A.* 154, 56; Vogt a. Henninger, *A. Ch.* [4] 27, 129; Jackson a. White, *Am.* 2, 159; *P. Am. A.* 14, 312; *B.* 13, 1217). Potash-fusion gives *p*-oxy-benzoic acid.

Salts.—KA′ (B.; J. a. W.)—KA′ aq (V. a. H.): sol. boiling alcohol.—NaA′: flat crystals (from water) or pearly scales (from alcohol).—BaA'_2 aq.—BaA'_2 2aq (J. a. W.): Needles.—CaA'_2 2aq.—CaA'_2 7aq (J. a. W.); trimetric crystals.—CuA'_2 2aq: pale green needles.—PbA'_2 aq (J. a. W.): long needles. — A′PbOH aq. — $A'_2Pb_2O_2$: Needles.

Chloride $C_6H_4Cl.CH_2.SO_2Cl$. [85·5°]: flat crystals, v. sol. ether.

CHLORO-*o*-TOLUIC ACID $C_6H_3(CH_3)Cl.CO_2H$ [2:4:1]. [130°]. Formed, together with the [6:3:1] isomeride [166°], by oxidation of chloro-*o*-xylene $C_6H_3(CH_3)_2Cl$ [1:2:4] with HNO_3 (Krüger, *B.* 18, 1757). Fine needles or thick prisms. By further oxidation by means of $KMnO_4$ both acids yield chloro-phthalic acid [130°-134°]. By KOH fusion it is converted into oxy-*o*-toluic acid $C_6H_3(CH_3)(OH)CO_2H$ [2:4:1].—CaA'_2 3aq.

Chloro-*p*-toluic acid $C_6H_3(CH_3)Cl(CO_2H)$ [4:2:1]. [150°]. Formed by the action of boiling dilute HNO_3 on chloro-cymene (derived from thymol and PCl_5). Slightly volatile with steam. (Fileti a. Crosa, *G.* 16, 290).

Chloro-*o*-toluic acid $C_6H_3(CH_3)Cl.CO_2H$[2:3:1]. [154°]. Formed by oxidation of chloro-*o*-xylene $C_6H_3(CH_3)_2Cl$ [1:2:3] by HNO_3 (Krüger, *B.* 18, 1758). Needles. V. sol. alcohol. By further oxidation by means of $KMnO_4$ it yields chloro-phthalic acid [181°].—A'_2Ca 2aq: sparingly soluble long prisms.

Chloro-*o*-toluic acid $C_6H_3(CH_3)Cl.CO_2H$[6:3:1]. [166°]. Formed, together with the isomeride (2:4:1), by oxidation of chloro-*o*-xylene $C_6H_3(CH_3)_2Cl$ [1:2:4], with HNO_3 (Krüger; *B.* 18, 1757). Needles. Sol. alcohol, v. sl. sol. water. By further oxidation by means of $KMnO_4$ both acids yield chloro-phthalic acid [130°-134°]. By KOH fusion it yields oxy-*o*-toluic acid [173°].—A'_2Ca 2aq: sparingly soluble short prisms.

Chloro-*p*-toluic acid $C_6H_3(CH_3)Cl(CO_2H)$ [4:3:1]. [196°]. Formed by the action of boiling dilute HNO_3 on the chloro-cymene that is obtained from carvacrol and PCl_5 (Fleischer a. Kekulé, *B.* 6, 1090; v. Gerichten, *B.* 10, 1249; 11, 366). Laminæ.—CaA'_2 3aq.—BaA'_2 4aq.

Chloro-*m*-toluic acid $C_6H_3(CH_3)Cl.CO_2H$ [3:4:1]. [203°] (V.); [210° cor.] (J.); [204° cor.] (R. a. K.).

Formation.—1. By oxidation of chloro-*m*-xylene $C_6H_3(CH_3)_2Cl$ [1:3:4] with $K_2Cr_2O_7$ and H_2SO_4 (Vollrath, *Bl.* [2] 7, 342; Jacobsen, *B.* 18, 1761). — 2. From $C_6H_3(CH_3)(NO_2)(CO_2H)$ [3:4:1] by displacement of NO_2 by Cl (Beilstein a. Kreusler, *A.* 144, 182; Remsen a. Kuhara, *Am.* 3, 431).

Properties.—Needles (from alcohol). By KOH fusion it gives oxy-*m*-toluic acid [173°].

Salts.—BaA'_2 3aq: slender needles (V.).—CaA'_2 3aq.

Ethyl ether EtA′. (263°).

ω-**Chloro-*o*-toluic acid** *Amide* [2:1] $CH_2Cl.C_6H_4.CONH_2$. [c. 180°]. From the nitrile and H_2SO_4 at 90°, followed by water (Gabriel, *B.* 20, 2234). Slender needles (from alcohol). Boiling water converts it into phthalide. At 160° it changes to oily 'pseudophthalimidine' C_8H_7NO.

Nitrile $CH_2Cl.C_6H_4.CN$. *o-Cyano-benzyl chloride.* [61°]. (252°). Formed by passing Cl into the boiling nitrile of *o*-toluic acid (Gabriel a. Otto, *B.* 20, 2223). Monoclinic crystals; $a:b:c = ·778:1:·294$; $\beta = 60° 2'$. Sol. hot water.

Di-chloro-toluic acid $C_6H_2(CH_3)Cl_2(CO_2H)$. [161°]. From crude di-chloro-xylene (222°) and chromic mixture (Hollemann, *A.* 144, 269).—CaA'_2 9aq.—AgA′.

Di-ω-chloro-toluic acid. *Nitrile* $CHCl_2.C_6H_4.CN$. *Cyano-benzylidene chloride.* (260°). Formed by the action of chlorine on the boiling nitrile of *o*-toluic acid (Gabriel a. Weise, *B.* 20, 3197). Fuming HCl at 170° gives $C_6H_4(CHO)(CO_2H)$. [97°].

Tri-ω-chloro-*o*-toluic acid. *Nitrile* $CCl_3.C_6H_4.CN$. *Cyano-benzyl trichloride.* [95°]. (c. 280°). From boiling *o*-toluic nitrile and Cl (G. a. W.). Monoclinic crystals (from alcohol); $a:b:c = 1·546:1:1·106$; $\beta = 73° 53'$.

***o*-CHLORO-*o*-TOLUIDINE** $C_6H_3(CH_3)Cl(NH_2)$ [1:2:6]. Formed by reduction of the corresponding nitro- compound (the nitration-product of *o*-chloro-toluene). Liquid.

Acetyl derivative $C_7H_6Cl.NHAc$: [136°]; white needles (Hönig, *B.* 20, 2417)

s-**Chloro-toluidine** $C_6H_3(CH_3)Cl(NH_2)$ [1:3:5]. (242°) at 730 mm. Formed by reduction of the corresponding nitro- compound. Liquid. Volatile with steam.—$B'HNO_3$: [198°], colourless needles.

Acetyl derivative $C_7H_6Cl(NHAc)$: [198°]; colourless needles (Hönig, *B.* 20, 2419).

Chloro-*p*-toluidine $C_6H_3(CH_3)Cl(NH_2)$ [1:3:4]. [7°]. (219° uncor.). Got by boiling its acetyl derivative with HCl. Elimination of NH_2 gives *m*-chloro-toluene.—B'HCl.—$B'HNO_3$. S. 2·59 at 19°.—$B'H_2SO_4$.—$B'H_2C_2O_4$.

Acetyl derivative $C_6H_3MeCl(NHAc)$ [1:3:4]. [115°]. Formed by chlorination of *p*-acet-toluide. Bad yield (Lellmann a. Klotz, *A.* 231, 309; *cf.* Wroblewsky, *A.* 168, 196).

***p*-Chloro-*o*-toluidine** $C_6H_3(CH_3)Cl(NH_2)$ [1:4:2]. [22°]. (237° at 722 mm.). Colourless liquid or white crystalline solid. Formed by reduction of (4:2:1)-chloro-nitro-toluene [38°].

Salts.—B'HCl: colourless needles.—$B'_2H_2Cl_2PtCl_4$ 2aq: fine yellow needles.

Acetyl derivative $C_6H_3(CH_3)Cl.NHAc$: [131°]; long slender colourless needles, v. sol. hot water, alcohol and ether, sl. sol. cold water (Goldschmidt a. Hönig, *B.* 19, 2440; *cf.* Engelbrecht, *B.* 7, 797; and Beilstein a. Kuhlberg, *A.* 158, 336).

Chloro-*p*-toluidine $C_6H_3(CH_3)(Cl)(NH_2)$ [1:2:4]. [26°]. (238°). Formed by reduction of chloro-nitro-toluene [65°] (Lellmann, *B.* 17, 535). Colourless crystalline solid. V. sol. all solvents except water. By diazotisation and treatment with alcohol it yields *o*-chloro-toluene.

Salts.—B'HCl: broad colourless needles.—$B'_2H_2SO_4$: small colourless plates.—$B'_2H_2PtCl_6$.

Acetyl derivative $C_6H_3MeCl(NHAc)$. [105°]. From $C_6H_3Me(NHAc).N_2.NC_5H_{10}$ and boiling HClAq (Wallach, *A.* 235, 254).

***p*-Chloro-*m*-toluidine** $C_6H_3(CH_3)Cl(NH_2)$ [1:4:3]. [28°] (G. a. H.); [30°] (G. a. K.). (230°). Formed by reduction of (4:3:1)-chloro-nitro-toluene [9°]. White crystalline solid. The base and its salts are extremely soluble.—B'HCl: colourless tables.

Acetyl derivative $C_6H_3(CH_3)Cl.NHAc$: [97°]; long silky needles, m. sol. water (Goldschmidt a. Hönig, *B.* 19, 2442; *cf.* Engelbrecht, *B.* 7, 797; and Gattermann a. Kaiser, *B.* 18, 2599).

Chloro-*o*-toluidine $C_6H_3(CH_3)Cl(NH_2)$ [1:5:2]. [30°]. (237° uncor.) at 730 mm. From its acetyl derivative (L. a. K.). The same compound ([30°], (241°)) appears to be a by-product in the reduction of *o*-nitro-toluene by tin and HCl (Beilstein a. Kuhlberg, *A.* 156, 81).

Salt.—B'HCl: sl. sol. water.

Acetyl derivative $C_6H_3Me(NHAc)Cl$. [140°]. Got by chlorination of acetylated *o*-toluidine (Lellmann a. Klotz, *A.* 231, 317).

***o*-Chloro-*m*-toluidine** $C_6H_3MeCl(NH_2)$ [1:2:5]. [83°]. (239°) at 215 mm. Obtained by reduction of the corresponding nitro- compound [44°] (Goldschmidt a. Hönig, *B.* 19, 2443; 20, 199; Wroblewsky, *A.* 168, 200; Henry a. Radziszewsky, *B.* 2, 308, 599). Formed also as a by-product in the reduction of *m*-nitro-toluene by zinc-dust and HCl (Kock, *B.* 20, 1567). Glistening colourless needles of characteristic odour.

Salts.—B'HCl: long slender needles.—$B'HNO_3$: [164°], broad colourless needles. S. 5·01 (W.).—$B'_2H_2SO_4$.

Acetyl derivative $C_6H_3MeCl(NHAc)$: [89°]; colourless plates.

Di-chloro-*p*-toluidine $C_6H_2(CH_3)Cl_2(NH_2)$ [1:3:5:4]. [60°]. Needles (from dilute alcohol). V. sol. alcohol and ether. Weak base. May be sublimed.

Acetyl derivative $C_6H_2Me(NHAc)Cl_2$ [1:4:3:5]. [201°]. From $C_6H_3Me(NHAc)Cl$ [1:4:3] by chlorination (Lellmann a. Klotz, *A.* 231, 322). White needles (from alcohol). V. sol. alcohol, insol. water, sol. ether and glacial acetic acid. May be sublimed.

(β)-Di-chloro-toluidine $C_6H_2(CH_3)Cl_2(NH_2)$. [1:2:4:?]. [87°]. (259°). Formed by reducing (β)-di-chloro-nitro-toluene [53°] (Seelig, *A.* 237, 163). Plates (from methyl alcohol).

Di-chloro-toluidine $C_6H(CH_3)Cl_2(NH_2)$ [1:2:4:6]. [88°]. (259°). Obtained by reducing di-chloro-nitro-toluene [-14°] (Wroblewsky, *A.* 168, 213). Does not combine with acids.

Tri-chloro-toluidine $C_6H(CH_3)Cl_3(NH_2)$ [1:2 4:6:3] or [1:2:4:5:6]. [91°] (Schultz, *A.* 187, 278); [95°] (Seelig, *B.* 18, 423). From tri-chloro-nitro-toluene [89°], tin and HCl. Needles (from alcohol).

Acetyl derivative $C_6H(CH_3)Cl_3(NHAc)$. [191°].

Benzoyl derivative $C_6H(CH_3)Cl_3(NHBz)$. [213°].

Tri-chloro-toluidine $C_6H(CH_3)Cl_3(NH_2)$ [105°]. From (β)-tri-chloro-nitro-toluene, $SnCl_2$, and HCl (Seelig, *B.* 18, 423). Needles.

CHLORO-TOLUQUINOLINE *v.* CHLORO-(*B.*)-METHYL-QUINOLINE.

CHLORO-TOLUQUINONE $C_6H_2(CH_3)ClO_2$. [1:4or3:2:5]. [90° uncor.]. Formed by oxidation of di-chloro-*o*-cresol with $K_2Cr_2O_7$ and dilute H_2SO_4. Long yellow needles. Volatile with steam, and sublimable. V. sol. alcohol, ether, &c., sol. hot water, sl. sol. cold. Dissolves in alkalis with a dark-red colour. By SO_2 it is reduced to chloro-hydrotoluquinone [115°] (Claus a. Sweitzer, *B.* 19, 929).

Chloro-toluquinone $C_6H_2(CH_3)ClO_2$. [105°]. From chloro-hydro-toluquinone [175°] by distillation with aqueous Fe_2Cl_6 (Schniter, *B.* 20, 2282).

Di-chloro-toluquinone $C_6H(CH_3)Cl_2O_2$ [1:2:4:3:6]. [103° uncor.]. Glistening yellow plates. Volatile with steam. Formed by oxidation of di-chloro-*m*-cresol with $K_2Cr_2O_7$ and H_2SO_4. Also from *m*-cresol, HCl, and $KClO_3$ (Southworth, *A.* 168, 270). Yellow tables (from alcohol). The corresponding di-chloro-hydro-toluquinone melts at [171°] (Claus a. Schweitzer, *B.* 19, 931).

Di-chloro-toluquinone $C_6H(CH_3)Cl_2O_2$ [1:?:?:2:5]. From *o*-cresol, $KClO_3$, and HCl (Southworth, *A.* 168, 274). Not obtained pure. Reduced by SO_2 to di-chloro-hydrotoluquinone [121°].

Tri-chloro-toluquinone $C_6(CH_3)Cl_3O_2$. [232°]. From *o*-cresol, HCl, and $KClO_3$ (Græbe a. Borgmann, *A.* 152, 248; Southworth, *A.* 168, 273; Knapp a. Schultz, *A.* 210, 176). Formed also by treating *o*-toluidine sulphonic acid with $KClO_3$ and HCl (Hayduck, *A.* 172, 209). Yellow plates; sl. sol. cold alcohol, v. sol. ether. Volatile with steam.

Tetra-chloro-toluquinone $CH_2Cl{:}C_6Cl_3O_2$. Occurs among the products of the action of HCl and $KClO_3$ on beech-wood creosote (Gorup-Besanez, *A.* 143, 159; Bräuninger, *A.* 185, 339). Golden scales. May be sublimed. Sl. sol. cold alcohol.

CHLORO-TOLUQUINOXALINE *Dihydride.* $C_9H_9N_2Cl$ *i.e.*

$C_6H_3(CH_3)\Big\langle\begin{matrix} NH.CH_2 \\ | \\ N{=}CCl \end{matrix}$. [77°].

Formed by heating oxy-di-hydro-toluquinoxaline with PCl_5. Long colourless needles. Insol. water, v. e. sol. other solvents. Volatile with steam (Leuckart a. Hermann, *B.* 20, 29).

Di-chloro-toluquinoxaline $C_9H_6N_2Cl_2$ *i.e.*

$$C_6H_3Me\Big\langle\begin{matrix} N:CCl \\ N:CCl \end{matrix}\Big\rangle \quad . \qquad [115°].$$

From di-oxy-toluquinoxaline (1 mol.) and PCl_5 (2 mols.) at 170° (Hinsberg, *A.* 237, 350). Needles (from chloroform and petroleum-ether). Insol. water.

DI-CHLORO-TOLUYL-BENZOIC ACID $CH_3.C_6H_4.CO.C_6H_2Cl_2.CO_2H$. *Di-chloro-phenyl tolyl ketone carboxylic acid.* From (β)-dichloro-phthalic anhydride, toluene, and Al_2Cl_6 (Le Royer, *A.* 238, 357).

CHLORO-(α)-TOLUYLIC ACID *v.* CHLORO-PHENYL-ACETIC ACID.

DI-CHLORO-DITOLYL [3:4:1]$C_6H_3MeCl.C_6H_3MeCl$[1:3:4]. [51°]. From di-amido-ditolyl by Sandmeyer's reaction (Stolle, *B.* 21, 1096). Laminæ (from alcohol). CrO_3 gives chloro-toluic acid [205°].

CHLORO-DI-TOLYL-*tert*-BUTYL ALCOHOL $CCl(C_6H_4Me)_2.CMe_2OH$. (c. 265°). From acetone-chloroform, toluene, and Al_2Cl_6 (Willgerodt a. Genieser, *J. pr.* [2] 37, 369).

Di-chloro-tolyl-*tert*-butyl alcohol $CCl_2(C_6H_4Me).CMe_2OH$. (c. 245°). From acetone-chloroform, toluene, and Al_2Cl_6 (W. a. G.).

CHLORO-TOLYLENE-*m*-DIAMINE $C_6H_2(CH_3)Cl(NH_2)_2$ [1:4:3:5]. [111°]. Formed by reduction of chloro-di-nitro-toluene [48°]. Gives the chrysoidine and Bismarck-brown reactions (Hönig, *B.* 20, 2420).

(β)-Di-chloro-tolylene-diamine $C_6H(CH_3)Cl_2(NH_2)_2$[1:2:4:5:6]. [110°]. Formed by reducing (β)-di-chloro-di-nitro-toluene [102°] (Seelig, *A.* 237, 164). Plates (from ligroïn). On boiling with HOAc for twenty-five hours the anhydro- base is formed [170°]; brownish needles (from alcohol).

(α)-Tri-chloro-tolylene-diamine $C_6(CH_3)Cl_3(NH_2)_2$. [196°]. Formed by reduction of tri-chloro-di-nitro-toluene [227°] (Seelig, *B.* 18, 422; *A.* 237, 143). White needles (from alcohol). CrO_3 oxidises it to a quinone.

Acetyl derivative $C_6(CH_3)Cl_3(NAc_2)_2$. [220°].

(β)-Tri-chloro-tolylene-diamine $C_6(CH_3)Cl_3(NH_2)_2$. [207°]. Formed by reducing tri-chloro-di-nitro-toluene [141°] with stannous chloride in alcoholic solution (Seelig, *A.* 237, 143). Needles (from petroleum ether). On boiling with HOAc an anhydro- base is formed, hence the substance is an orthodiamine.

ω-CHLORO-DI-TOLYL-ETHANE $CH_2Cl.CH(C_6H_4.CH_3)_2$. From $CH_2Cl.CHCl.OEt$ (di-chloro-ether), toluene, and H_2SO_4 (Hepp, *B.* 7, 1413). Alcoholic KOH gives $CH_2:C(C_6H_4Me)_2$.

Tri-ω-chloro-di-tolyl-ethane $CCl_3.CH(C_6H_4.CH_3)_2$. [89°]. S. (ether) 50; (alcohol) 2·5. From chloral, toluene, and H_2SO_4 (O. Fischer, *B.* 7, 1191).

DI-CHLORO-DI-TOLYL-ETHYLENE $CCl_2:C(C_6H_4.CH_3)_2$. [92°]. S. (ether) 50; (alcohol) 2·9. From the preceding body and alcoholic KOH (O. Fischer, *B.* 7, 1191). Needles.

DI-CHLORO-DI-TOLYL-METHANE $CH_2(C_6H_4.CH_2Cl)_2$. [108°]. From benzyl chloride, methylal $CH_2(OMe)_2$, and H_2SO_4. Laminæ (Weiler, *B.* 7, 1181).

***o*-CHLORO-*m*-TOLYL-PHENYL-THIO-UREA** $C_6H_5.NH.CS.NH.C_6H_3MeCl$ [5:1:2]. [109°]. White granules. From $C_6H_3MeCl(NH_2)$[1:2:5] and phenyl-thiocarbimide (Goldschmidt a. Hönig, *B.* 20, 201).

CHLORO-TROPIC ACID $C_9H_9ClO_3$ *i.e.* $C_6H_5.CCl(CO_2H).CH_2OH$. [128°–130°]. From atropic acid and HClO (Ladenburg a. Rügheimer, *A.* 217, 109). V. e. sol. water, sl. sol. benzene. Reduced by zinc-dust, iron filings, and KOH to tropic acid.

CHLOROUS. Adjective sometimes used as synonymous with *negative* or *acidic*; generally applied to radicles which combine with *basylous* radicles to form salts, *e.g.* the radicles SO_3, N_2O_5, ClO_3 are called *chlorous*, as distinguished from K_2O, CaO, &c., which are basylous. The term chlorous is also sometimes applied to the more negative elements, especially to those which, like chlorine, do not displace the H of acids to form salts. The correlative term is *basylous*.

M. M. P. M.

CHLOROUS ACID $HClO_2$; *v.* CHLORINE, OXY-ACIDS OF, p. 17.

α-CHLORO-ISOVALERIC ACID $C_5H_9ClO_2$ *i.e.* $(CH_3)_2CH.CHCl.CO_2H$. From sodium isovalerate and aqueous HOCl (Schlebusch, *A.* 141, 322). Oil; decomposed by heat.

Tri- and tetra-chloro-isovaleric acids were obtained by Dumas a. Stas by chlorinating isovaleric acid in the dark. They decompose between 110° and 150°, giving off HCl.

CHLORO-ISOVALERIC ALDEHYDE C_5H_9ClO. (135°). S.G. $\frac{14}{}$ 1·108. From isovaleric aldehyde and Cl at −18° (Schröder, *B.* 4, 402). Combines with $NaHSO_3$.

Di-chloro-isovaleric aldehyde $C_5H_8Cl_2O$ (147°). From isovaleric aldehyde and Cl at 15°. Combines with $NaHSO_3$ (Kundig, *A.* 114, 1).

TRI-CHLORO-VALEROLACTIC ACID *v.* TRI-CHLORO-OXY-VALERIC ACID.

CHLORO-VALERO-LACTONE *v.* CHLORO-OXY-VALERIC ACID, *Anhydride of.*

DI-CHLORO-VALERYLENE $C_5H_6Cl_2$ *i.e.* $CH_2:CCl.CH_2.CCl:CH_2$. *Di-chloro-di-vinyl-methane.* (145°). Formed by the action of PCl_5 upon acetyl-acetone. Liquid; boils without decomposition. Readily takes up Br, forming $C_5H_6Cl_2Br_4$. Heated with alcoholic KOH it gives $CH:C.CH_2.C(OC_2H_5):CH_2$ (Combes, *A. Ch.* [6] 12, 222).

DI-CHLORO-*o*-VINYL-BENZOIC ACID $C_2HCl_2.C_6H_4.CO_2H$. [121°]. From tri-chloro-oxy-indonaphthene $C_6H_4\Big\langle\begin{matrix} CO \\ CHCl \end{matrix}\Big\rangle CCl_2$ by solution in aqueous alkalis (Zincke, *B.* 20, 2890). Slender needles (from dilute alcohol). Sodium amalgam converts it into *o*-ethyl-benzoic acid [68°].

Methyl ether MeA'. [47°].

***o-Exo*-tri-chloro-vinyl-benzoic acid** $C_6H_4(CCl:CCl_2)CO_2H$[1:2]. [161°].

Formation.—1. By the action of NaOHAq on tetra-chloro-oxy-indonaphthene $C_6H_4\Big\langle\begin{matrix} CO \\ CCl_2 \end{matrix}\Big\rangle CCl_2$ (Zincke, *B.* 20, 2053).—

2. Tetrachloro-(β)-naphtho-quinone is dissolved in NaOHAq, HOAc added, and the mixture oxidised with chromic acid (Zincke, *B.* 21, 499).

Properties.—Needles or plates. V. sol. alcohol and HOAc. Sodium amalgam yields *o*-ethyl benzoic acid.

Methyl ether A'Me. [75°].

CHLORO-VINYL ETHYL OXIDE C_4H_7ClO *i.e.* CH_2:CCl.OEt. (123°). S.G. ^{22} 1·02 (Geuther); ^{12} 1·036 (Godefroy). V.D. 3·52. From tri-chloro-ethane $CH_3.CCl_3$ and NaOEt at 120° (Geuther, *Z.* 1871, 128). Formed also by the action of zinc-dust or the zinc-copper couple on the compound $C_6H_{12}Cl_2O_2$ obtained by passing chlorine through a mixture of alcohol and $K_2Cr_2O_7$ (Godefroy, *C. R.* 102, 869).

Reactions.—1. Br forms CH_2Br.CClBr.OEt (170°–180°), whence Cl forms $CH_2Cl.CCl_2$.OEt.—2. HCl forms CH_2Cl.CHCl.OEt.—3. HNO_3 gives acetic and chloro-acetic acids.—4. Reduces ammoniacal $AgNO_3$, forming a mirror.—5. Exposed to the air it rapidly changes to a vitreous mass $(C_4H_7ClO)_3$aq.

Di-chloro-vinyl ethyl oxide CHCl:CCl.OEt. (128° cor.). S.G. ^{10} 1·08. Formed by the action of NaOEt upon $CH_2Cl.CHCl_2$ (Geuther a Brockhoff, *J. pr.* [2] 7, 112) or $CClH:CCl_2$ (Paternò a. Oglialoro, *B.* 7, 81). Water at 180° forms glycollic acid.

Di-chloro-vinyl ethyl oxide CCl_2:CH.OEt. (145°). From $CHCl_2$.CHCl.OEt and conc. aqueous KOH (Godefroy). Sweet-smelling oil. Reduces ammoniacal $AgNO_3$, forming a mirror. Greedily combines with Br.

Tri-chloro-vinyl ethyl oxide CCl_2:CCl.OEt. (155°) (B.); (c.160°) (G.). S.G. ^{0} 1·373; ^{100} 1·235 (P. a. P.); ^{12} 1·332 (G.).

Formation.—1. From $CCl_2:CCl_2$ and NaOEt at 110° (Geuther a. Fischer, *J.* 1864, 316).—2. From CCl_3.CHCl.OEt and conc. aqueous KOH (Paternò a. Pisati, *G.* 2, 333; Godefroy, *C. R.* 102, 869; Busch, *B.* 11, 446). Smells like mint. Br forms CCl_2Br.CClBr.OEt [17°]. Cl gives $C_2Cl_5.O.C_2H_5$.

CHLORO-DI-VINYL-METHANE *v.* Di-chloro-valerylene.

HEXA-CHLORO-DI-VINYL OXIDE C_4Cl_6O *i.e.* $(CCl_2:CCl)_2O$. *Chloroxethose.* (210°). S.G. ^{21} 1·652. From $(C_2Cl_5)_2O$ and alcoholic K_2S (Malaguti, *A. Ch.* [3] 16, 19). Br forms $C_4Cl_6Br_4O$ [96°].

CHLOROX- *v.* Chloro-ox-.

CHLOROXAL- *v.* Chloro-oxal-.

CHLOROXETHOSE *v.* Hexa-chloro-di-vinyl oxide.

CHLOROXY- *v.* Chloro-oxy-.

CHLORO-*o*-XYLENE $C_6H_3(CH_3)_2Cl$ [1:2:3]. Mol.w.140½. (190° cor.). Fluid at −10°. Formed, together with the (1:2:4)-isomeride, by chlorination of *o*-xylene in presence of 5 p.c. of iodine. By dilute HNO_3 it is oxidised to chloro-toluic acid [154°], which by $KMnO_4$ is further oxidised to chloro-phthalic acid [181°] (Krüger, *B.* 18, 1755).

Chloro-*o*-xylene $C_6H_3(CH_3)_2Cl$ [1:2:4]. (192° cor.). Fluid at −20°. S.G. $\frac{15}{15}$ 1·0692. Formed, together with the (1:2:3)-isomeride, by chlorination of *o*-xylene in presence of 5 p.c. of iodine. By dilute HNO_3 it is oxidised to two isomeric chloro-toluic acids [166°] and [130°], which by further oxidation with $KMnO_4$ yield chloro-phthalic acid [130°–134°] (Krüger, *B.* 18, 1755).

Chloro-*o*-xylene $C_6H_3(CH_3)_2Cl$. (205° uncor.). S.G. ^{12} 1·0863. Colourless, strongly refractive liquid. According to Claus a. Kautz (*B.* 18, 1367) this is the only chloro-*o*-xylene formed by chlorination of *o*-xylene in the cold in presence of iodine. It is readily oxidised by dilute HNO_3 to chloro-phthalic acid.

Chloro-*m*-xylene $C_6H_3(CH_3)_2Cl$ [1:3:4]. (186° cor.). S.G. $\frac{20}{20}$ 1·0598. Fluid at −20°. Formed by chlorination of *m*-xylene in presence of 5 p.c. of iodine. By $K_2Cr_2O_7$ and H_2SO_4 it is oxidised to chloro-*m*-toluic acid $C_6H_3(CH_3)Cl.CO_2H$ [3:4:1] of melting-point [210°] (Jacobsen, *B.* 18, 1760; *cf.* Vollrath, *Z.* 1866, 488).

Chloro-*p*-xylene $C_6H_3(CH_3)_2Cl$ [1:4:2]. [+2°]. (186° cor. at 767 mm.). Formed by chlorination of *p*-xylene in presence of I (Kluge, *B.* 18, 2099).

ω-Chloro-*o*-xylene $C_6H_4(CH_3)(CH_2Cl)$ [1:2]. (198°).

Formation.—1. By chlorinating boiling *o*-xylene (Reyman, *Bl.* [2] 26, 534).—2. By heating $C_6H_4(CH_3)(CH_2OH)$ [1:2] with conc. HCl. It cannot, however, be obtained pure in this way (Colson, *A. Ch.* [6] 6, 117).

Reaction.—Boiling aqueous $Pb(NO_3)_2$ gives *o*-toluic aldehyde.

ω-Chloro-*m*-xylene $C_6H_4(CH_3)(CH_2Cl)$ [1:3]. So-called *m-Tolyl chloride.* (196°). S.G. ^{0} 1·079.

Formation.—1. From Cl and boiling *m*-xylene (Vollrath; Lauth a. Grimaux, *Bl.* [2] 7, 233; *A.* 145, 115; Gundelach, *C. R.* 82, 1444).—2. By the action of HCl upon $C_6H_4(CH_3).(CH_2OH)$ [1:3] (Colson, *A. Ch.* [6] 6, 118).

ω-Chloro-*p*-xylene $C_6H_4(CH_3)(CH_2Cl)$ [1:4]. (192°). From Cl and boiling *p*-xylene (L. a. G.).

Di-chloro-*o*-xylene $C_6H_2(CH_3)Cl_2$. [3°]. (227°). Colourless strongly refractive liquid. Formed by chlorination of *o*-xylene in the cold in presence of iodine. It is readily oxidised by dilute HNO_3 to di-chloro-phthalic acid [183°] (Claus a. Kautz, *B.* 18, 1367).

Di-chloro-*m*-xylene $C_6H_2(CH_3)_2Cl_2$. (222°). From *m*-xylene and Cl in presence of iodine (Hollemann, *Z.* 1865, 554; *A.* 144, 268). White laminæ; melts by the heat of the hand.

Di-chloro-*p*-xylene $C_6H_2(CH_3)_2Cl_2$ [1:4:2:5]. [71°]. (221° i. V.).

Formation.—1. By chlorination of *p*-xylene. 2. From chloro-*p*-xylidine [92°] by diazotisation and treatment with Cu_2Cl_2 (Kluge, *B.* 18, 2098). Plates or flat needles. V. sol. hot alcohol and ether, sl. sol. cold alcohol.

ωω-Di-chloro-*o*-xylene (1.2)$C_6H_4(CH_2Cl)_2$. [55°]. (240°). S.G. ^{0} 1·393. S.H. (15° to 40°) ·283.

Formation.—1. By the action of HCl on ωω-di-oxy-*o*-xylene (Hessert, *B.* 12, 648; Colson, *Bl.* [2] 43, 7).—2. By heating *o*-xylene (10 c.c.) with PCl_5 (35 g.) at 180°–200° (Colson a. Gautier, *Bl.* [2] 45, 6; *C. R.* 101, 1064; 104, 428; Strassmann, *B.* 21, 578).

Properties.—White crystals; v. sol. ether, alcohol, ligroïn, and chloroform. Converted by heating with water into $C_6H_4(CH_2OH)_2$ [62°]. Potassium phthalimide reacts with formation of $CH_2Cl.C_6H_4.CH_2.N:C_8H_4O_2$ [140°] (Strassmann, *B.* 21, 576).

Di-chloro-*o*-xylene $C_6H_4(CH_3)(CHCl_2)$(?). [103°]. (225°). From Cl and boiling *o*-xylene (Reyman, *Bl.* [2] 26, 534)

ω-Di-chloro-*m*-xylene $C_6H_4(CH_2Cl)_2$[1:3]. [34°]. (253°). S.G. ^{20} 1·302. S.H. (15° to 40°) ·295.

Formation.—1. From $C_6H_4(CH_2OH)_2$ [1:3] and HCl (Colson, *Bl.* [2] 43, 7). By heating *m*-xylene at 180° with the equivalent amount of PCl_5. The yield is not so good as with the *o*- and *p*-compounds, and to obtain it pure it is necessary to saponify the crude product and treat the glycol so produced with HCl (Colson a. Gautier, *Bl.* [2] 45, 6; *A. Ch.* [6] 6, 114).

Di-ω-chloro-*p*-xylene $C_6H_4(CH_2Cl)_2$ [1:4]. [100°]. (240°-250°). S.G. ^{0} 1·417. S.H. (15° to 40°) ·282.

Formation.—1. From Cl and boiling *p*-xylene (Lauth a. Grimaux, *A.* 145, 115).—2. From $C_6H_4(CH_2OH)_2$ [1:4] and HCl.—3. By heating *p*-xylene at 180° with the equivalent amount of PCl_5 (Colson a. Gautier, *Bl.* [2] 45, 6).

Properties.—Tables (from alcohol). Heated with water it gives the glycol $C_6H_4(CH_2OH)_2$. [113°] (Grimaux, *C. R.* 70, 1363).

Tri-chloro-*o*-xylene $C_6H(CH_3)_2Cl_3$. [93°]. (265° uncor.). Formed by chlorination of *o*-xylene in the cold in presence of iodine (Claus a. Kautz, *B.* 18, 1367). Long colourless glistening needles. V. sol. ether, benzene, hot acetic acid, and hot alcohol, v. sl. sol. cold alcohol. It is readily oxidised by dilute HNO_3 to tri-chloro-phthalic acid, the anhydride of which melts at [157°].

Tri-chloro-*m*-xylene $C_6H(CH_3)_2Cl_3$. [150°]. (255°). From *m*-xylene and Cl in presence of iodine (Hollemann, *A.* 144, 270). Silky needles: v. sol. hot, sl. sol. cold, alcohol.

Tetra-chloro-*o*-xylene $C_6(CH_3)_2Cl_4$. [215° uncor.]. Formed by chlorination of *o*-xylene in the cold in presence of iodine (Claus a. Kautz, *B.* 18, 1367). Sublimable. Long colourless needles. Not volatile with steam. Sol. ether, benzene, hot acetic acid, and hot alcohol, sl. sol. cold alcohol. It is not oxidised by heating with HNO_3.

Tetra-ω-chloro-*o*-xylene $C_6H_4(CHCl_2)_2$ [1:2]. [86°] (C. a. G.); [89°] (H.). (274°). S.G. ^{0} 1·601. S. (ether) 50 at 15°; 100 at 35°. S.H. (15°-60°) ·24.

Formation.—1. From Cl and boiling *o*-xylene (Hjelt, *B.* 18, 2879).—2. From PCl_5 and *o*-xylene at 150° (Colson a. Gautier, *Bl.* [2] 45, 10).

Properties.—Triclinic crystals (from ether) $a:b:c = ·972:1:·741$; $\alpha = 54°\ 38'$; $\beta = 54°\ 20'$; $\gamma = 58°\ 24'$. Its solubility in petroleum ether is double that of the *p*-compound. Sol. C_6H_6, $CHCl_3$, and alcohol. Water at 170° converts it into phthalide.

Tetra-ω-chloro-*m*-xylene $C_6H_4(CHCl_2)_2$. (273°). S.G. 1·536 (Colson a. Gautier, *Bl.* [2] 45, 509).

Tetra-ω-chloro-*p*-xylene $C_6H_4(CHCl_2)_2$ [1:4]. [93°]. S.G. ^{0} 1·606. S.H. (15° to 60°) ·242. S. (ether) 50 at 35°; S. (ligroïn) 7. Formed by heating *p*-xylene ($5\frac{1}{4}$ c.c.) and pure PCl_5 (40 g.) at 195°, and crystallising the product from ether (Colson a. Gautier, *Bl.* [2] 45, 9). Saponified by boiling with water gives terephthalic aldehyde $C_6H_4(COH)_2$ [1:4]. [114°].

Penta-ω-chloro-*o*-xylene $C_6H_4(CCl_3)(CHCl_2)$ [1:2]. [54°]. From *o*-xylene (3·2 c.c.) and PCl_5 (40 g.) at 200° (Gautier a. Colson, *C. R.* 102, 689). Converted by boiling water into $C_6H_4(CO_2H)(CHO)$. [97°].

Hexa-chloro-*m*-xylene $C_8H_4Cl_6$ [1:3]. (c. 286°). From *m*-xylene and PCl_5 (Colson a. Gautier, *C. R.* 102, 689). Converted by alkalis into a chlorinated acid.

Hexa-ω-chloro-*p*-xylene $C_6H_4(CCl_3)_2$ [1:4]. [111°]. Formed by heating *p*-xylene (1 mol.) with PCl_5 (6·5 mol.) for 10 hours at 200°. Transparent crystals. Sol. ether. Heated with a solution of NaHO, it loses all its chlorine, forming terephthalic acid (Colson a. Gautier, *Bl.* [2] 45, 507).

CHLORO-*o*-XYLENE-SULPHONIC ACID $C_6H_2(CH_3)_2Cl.SO_3H$ [1:2:4:5]. Formed by sulphonation of chloro-*o*-xylene (1:2:4) (Krüger, *B.* 18, 1756). On reduction with sodium amalgam it gives *o*-xylene-sulphonic acid (1:2:4).

Salts.—A′Na 5aq: glistening needles or large flat prisms.—A′K: short needles.—A′₂Ba 4aq: long needles, sol. hot water, more sparingly in cold.

Amide $C_6H_2Me_2Cl.SO_2NH_2$: [207°]; long felted needles, sol. hot, sl. sol. cold, alcohol, v. sl. sol. water.

Chloro-*o*-xylene-sulphonic acid $C_6H_2(CH_3)_2Cl.SO_3H$ [1:2:3:6]. Formed by sulphonation of chloro-*o*-xylene (1:2:3) (Krüger, *B.* 18, 1756).

Salts.—A′Na aq: large pearly plates.—A′K: plates.—A′₂Ba aq: thin glistening plates.

Amide $C_6H_2Me_2Cl.SO_2NH_2$: [199°]; fine silky needles or long prisms, sol. hot alcohol, sl. sol. water.

Chloro-*m*-xylene-sulphonic acid $C_6H_2(CH_3)_2Cl.SO_3H$ [1:3:4:6]. Formed by sulphonation of chloro-*m*-xylene, $C_6H_3(CH_3)_2Cl$ [1:3:4] (Gundelach, *Bl.* [2] 28, 343; Jacobsen, *B.* 18, 1761).

Salts.—A′Na aq: long fine needles, sl. sol. cold water.—A′K aq: needles, v. e. sol. water.—A′₂Ba very sparingly soluble small tables.

Amide $C_6H_2(CH_3)_2Cl.SO_2NH_2$. [195°]. Prisms (from alcohol).

Chloro-*p*-xylene-sulphonic acid $C_6H_2(CH_3)_2Cl.SO_3H$. Formed by sulphonation of chloro-*p*-xylene.

Salts.—A′Na aq; easily soluble prisms.—A′₂Ba aq: sparingly soluble needles (Kluge, *B.* 18, 2099).

CHLORO-*m*-XYLIDINE $C_8H_{10}ClN$. [89°]. From (2,3,1)-nitro-*m*-xylene, tin, and HCl (Tavildaroff, *Z.* 1870, 419). Crystalline.

Chloro-*p*-xylidine $C_6H_2(CH_3)_2Cl.NH_2$ [1:4:2:5]. [92°]. Formed by the action of tin and HCl upon nitro-*p*-xylene (Jannasch, *A.* 176, 55). Laminæ (from water). By diazotising and treatment with cuprous chloride it yields di-chloro-*p*-xylene [71°].

Salts.—B′HCl 2aq.—$B'_2H_2SO_4$ 2aq.—$B'_2H_2C_2O_4$.

Acetyl derivative $C_6H_2Me_2Cl.NHAc$—[171°], colourless needles (Kluge, *B.* 18, 2098).

CHLORO-XYLO-HYDROQUINONE *v.* CHLORO-HYDRO-XYLOQUINONE.

CHLORO-XYLOQUINONE $C_6HClMe_2O_2$ [*x*:1:4:2:5]. *Chloro-phlorone.* [48°]. Conc. HCl dissolves xyloquinone, but immediately a brown crystalline mass separates. This is a mixture of mono- and di-chloro-hydro-xyloquinones. If it be oxidised by CrO_3 or HNO_3 a mixture of mono- and di-chloro-xyloquinones is got. From alcohol the former crystallises in needles, the latter in plates (Carstanjen, *J. pr.* [2] 23, 430; *cf.* V. Rad, *A.* 151, 158). Chloro-xyloquinone is converted by boiling with HCl into di-chloro-hydro-xyloquinone.

Di-chloro-xyloquinone $C_6Cl_2Me_2O_2$. [175°]. Prepared as above. Not affected by boiling HCl.

a-DI-CHLORO-*o*-XYLYLENE-DI-MALONIC ETHER $C_6H_4[CH_2.CCl(CO_2Et)_2]_2$. From sodium chloro-malonic ether and $[1:2]C_6H_4(CH_2Br)_2$ (Baeyer a. Perkin, *B.* 17, 452; *C. J.* 53, 14). Liquid. Alcoholic KOH gives *o*-phenylene-di-acrylic acid.

Di-chloro-*m*-xylylene-di-malonic ether $C_6H_4(CH_2.CCl(CO_2Et)_2)_2$. Formed by the action of chloro-malonic ethyl ether and sodium ethylate on *m*-xylylene dibromide (Kipping, *C. J.* 53, 26). Thick yellowish oil.

Di-chloro-*p*-xylylene-di-malonic ether $C_6H_4[CH_2.CCl(CO_2Et)_2]_2$. [87°]. Formed by acting with ethyl chloromalonate and sodium ethylate on *p*-xylylene dibromide (Kipping, *C. J.* 53, 35). Colourless six-sided plates. Insol. water, v. sol. alcohol, ether, petroleum ether, and HOAc.

CHLORO-DI-XYLYL-ETHANE $C_{18}H_{21}Cl$ *i.e.* $CH_2Cl.CH(C_6H_3Me_2)_2$. From di-chlorinated ether $CH_2Cl.CHCl.OEt$, xylene, and H_2SO_4 (Hepp, *B.* 7, 1416). On distillation it splits up into HCl and $CH_2{:}C(C_6H_3Me_2)_2$.

CHOLALIC ACID *v.* CHOLIC ACID.

CHOLANIC ACID $C_{25}H_{38}O_7\,\frac{1}{4}$aq. [285°] (L.). S. ·025 at 100°; ·011 at 20° (L.; *cf.* Kutscheroff, *B.* 14, 1492); S. (alcohol of 98·5 p.c. at 18°) 1·37. $[\alpha]_D = 53°$ (T.); 88° (Kutscheroff). Formed by oxidation, with $K_2Cr_2O_7$ and H_2SO_4, of choleic acid $C_{25}H_{42}O_4$, of dehydrocholeic acid $C_{25}H_{38}O_4$, and also (according to L.) of desoxycholic acid (Tappeiner, *A.* 194, 231; Latschinoff, *B.* 13, 1052; 18, 3045; 19, 474, 1521; 20, 1044; *Bl.* [2] 46, 818). Large tables or flat prisms. Tribasic acid. Dextro-rotatory. On further oxidation by boiling with HNO_3 (1·28 S.G.), it gives choloïdanic acid and pseudo-choloïdanic acid.

Salts.—A'''_2Ba_3 6aq: tables or plates; S. (at 18°) 4·12; $[\alpha]_D = +49·37°$.

Mono-methyl ether $A'''H_2Me$: [207°]; very slender needles; v. sol. alcohol, less sol. ether; the Na, K, Ca, and Ba salts are v. sol. water and alcohol.—$A'''MeBa$.

Mono-ethyl ether $A'''H_2Et$: [190°]; the properties are the same as those of the mono-methyl ether.—$A'''EtBa$.—$A'''EtPb$.

Di-methyl ether $A'''HMe_2$: [176°]; needles.

Di-ethyl ether $A'''HEt_2$: [131°].—A'''_2Et_4Ba.—A'''_2Et_4Pb.

Tri-methyl ether $A'''Me_3$: [121°]; needles.

Tri-ethyl ether $A'''Et_3$: [76°]; needles.

***Iso*-cholanic acid** $C_{25}H_{38}O_7$(?) [248°]. $[\alpha]_D = 73·3°$. S. ·022; S. (alcohol) 9·1; S. (ether) ·018. Formed in small quantity, together with cholanic acid, by oxidation of choleic acid, with $K_2Cr_2O_7$ and H_2SO_4 (Latschinoff, *B.* 15, 713; 19, 1529). The cholanic acid described by Tappeiner appears to be contaminated with a small quantity of this isomeric acid. Pearly plates. Penta-basic acid.

Salts.—$A^{v}K_5$: soluble hair-like needles.—$A^{v}K_2H_3$: fine needles.—$A^{v}_2Ba_5$ 10aq?: sparingly soluble amorphous powder. — $A^{v}Ba_2H$. — $A^{v}_2Pb_5$ 6aq: amorphous pp., insol. water and alcohol.—$A^{v}Ag_5$: insoluble amorphous pp.—$A^{v}_2Cu_3Cu_4O_4$ 10aq: amorphous blue pp.

Methyl ether $C_{25}H_{33}O_7Me_5$: [136°]; plates. From the lead salt and MeI.

Ethyl ether $C_{25}H_{33}O_7Et_5$: [43°-50°]; flat needles.

CHOLECAMPHORIC ACID *v.* CHOLOÏDANIC ACID.

CHOLEÏC ACID $C_{25}H_{42}O_4$(?). [185°-190°]. S. (water at 20°) ·0045; (75 p.c. alcohol at 20°) 4; (absol. alcohol at 20°) 7·1; (absol. ether at 20°) ·133. With 200 mm. of a 6·06 p.c. solution in absol. alcohol at 20°, $[\alpha]_D = 56°40'$. From alcohol or acetic acid it crystallises in hemihedral rhombic needles, $a{:}b{:}c = 1{:}·5057{:}1·8598$. Occurs in saponified ox-gall together with cholic and desoxycholic acids. It gives Pettenkofer's test for bile acids (Mylius, *H.* 11, 492). On gentle oxidation with CrO_3 and acetic acid it is converted into dehydrocholeic acid $C_{25}H_{38}O_4$, by more vigorous oxidation, with $K_2Cr_2O_7$ and H_2SO_4, into cholanic acid (but no bilianic acid). According to Latschinoff by boiling with glacial acetic acid it is converted into desoxycholic acid (called by him 'hydrated choleic acid'); Mylius, however, was unable to confirm this statement.

Salts.—$A'Ag$.—A'_2Ba: microscopic plates, insol. strong alcohol and water, v. sol. dilute alcohol forming the hydrated salt.—A'_2Ba 6aq: needles, v. sol. dilute alcohol, S. (water at 20°) ·083 (Latschinoff, *Bl.* [2] 46, 817; *B.* 18, 3039; 19, 1140; 20, 1043, 1053; Mylius, *B.* 19, 369; 20, 1968).

Dehydrocholeic acid $C_{25}H_{38}O_4$ (?) according to L. [183° uncor.]. Obtained by slowly adding a 10 p.c. solution of CrO_3 (3 pts.) in acetic acid to a 10 p.c. solution of choleic acid (4 pts.) in acetic acid; the yield is 60 to 70 p.c. According to L. it is also formed by similar treatment from desoxycholic acid. Silky tables. Less soluble in water and alcohol than dehydrocholic acid. By further oxidation with $K_2Cr_2O_7$ and H_2SO_4 it yields cholanic acid.—$A''Ba\,1\frac{1}{2}$aq: needles, v. sol. alcohol, sl. sol. water (Latschinoff, *B.* 18, 3045; 20, 1044).

CHOLESTERIN (*Animal cholesterin*) $C_{26}H_{44}O$,aq, or $C_{25}H_{42}O$,aq, or $C_{27}H_{46}O$aq. [146°, Hesse] [147·5°, or cor. = 148·5°, Reinitzer] [usually given at 145° to 146°].[1] $[\alpha]_D$ for anhydrous cholesterin from gallstones in chloroform = (−36·61 + 0·249 p.) (O. Hesse). This rotation depends to some extent on the strength of the solution. S.G. $\frac{0}{20}$ 1·046 (Mehu, *J. Ph.* [4] 20, 175); 1·067 (Hoppe-Seyler, *Gmelin's Handb.*, 18, 113), 1·03 after fusion (Hein., *ibid.*).

Occurrence.—This substance was first obtained by Conradi in 1755 from human gallstones, of which it sometimes constitutes nearly the entire substance. It has been found in human bile (Chevreul, *A. Ch.* 95, 5; 96, 166); in the blood (Lecanu, *A. Ch.* 67, 54; Boudet, *ibid.* 336; Denis, *J. Chim. Med.* [2] 4, 161; Becquerel a. Bodier, *Gaz. Med.* 47); together with protagon as an essential constituent of the nervous tissue, of the yolk of egg, of the seminal fluid, and of the red and white corpuscles of the blood (Hoppe-Seyler, *Med. Chem.*

---

[1] When cholesterin is mixed with iso-cholesterin, the melting point is lowered.

Unters. 1, 140; *J.* 1866, 744); in the brain (Couerbe, *A. Ch.* 56, 281; Fremy, *ibid.* [3] 11, 486; Beneke, *Bied. Centr.* 1881, 568)—the brain of a boy 15 years old was found to contain 26·92 g. cholesterin = 2·34 p.c., that of a woman 19 years old, 26·79 g. = 2·12 p.c. (Beneke); in the yolk of egg (Lecanu, *J. Ph.* 15, 1; Gobley, *ibid.* [3] 12, 12—four hen's eggs yielded 0·592 g., and four newly hatched chickens 0·41 g. (Beneke); in oxen bile (Hüfner, *J. pr.* [2] 19, 305); in human milk to the amount of 0·0318 p.c. (Tolmatscheff, *Med.-Chem. Unters.* 1, 272); in cow's milk (Schmidt a. Mülheim, *Archiv f. d. ges. Physiol.* 25, 384); in the spleen, and abundantly in the excrements of the crocodile (Marcet, *A. Ch.* [3] 59, 91); in guano (Hoppe-Seyler, *J.* 1863, 654); in the corpus luteum of the cow (Lieben, *Z.* 4, 646); along with paracholesterin in the protoplasm of *ethalium septicum* (Reinke a. Rodewald, *A.* 207, 228); along with iso-cholesterin in the grease of sheep's wool (Hartmann, *Inaug. Dissert. Göttingen*, 1868; E. Schulze, *Z.* [2] 6, 453); and in certain morbid products of the animal economy, such as cerebral concretions, scirrhous matter of the mesocolon, hydropic liquid of the abdomen, ovaries, testicles, &c. (Lassaigne, *A. Ch.* 9, 324; O. Henry, *J. Chim. Med.* 1, 280; Caventou, *J. Ph.* 11, 462; Lehmann, *Lehrb. d. Physiol. Chem.* 2te Aufl. 1, 286).

The first exact analysis of cholesterin was made by Chevreul, who assigned to it the formula $C_{26}H_{44}O$. Its metamorphoses have been studied by Marchand (*J. pr.* 16, 37); Redtenbacher (*A.* 57, 145); Meissner a. Schwendler (*ibid.* 59, 107, also *J. pr.* 39, 247); Zwenger (*A.* 66, 5; 69, 347); Heintz (*P.* 79, 521); Berthelot (*A. Ch.* [3] 56, 51); and by others, who will be referred to in the course of this article.

Preparation.—1. By crystallising biliary calculi from boiling alcohol, to which a little potash is added to dissolve any fatty acids that may be present.—2. By extracting brain substance with ether, and boiling the evaporated extract with alcoholic potash.—3. From the grease of sheep's wool by saponifying for 20 hours at 100° with alcoholic potash in a closed stoneware bottle, evaporating the alcohol, taking up with water and shaking with ether. The residue from the evaporation of the ether consists of a mixture of cholesterin, iso-cholesterin, and a nearly-related amorphous alcohol poorer in carbon,[2] and these are best separated from one another by conversion into their benzoic ethers, by fusing the mixture of alcohols (2 parts) with benzoic anhydride (1 part) to about 180° for 48 hours. The resulting mass is rubbed up with a little alcohol in a mortar, treated first with a cold solution of Na_2CO_3, and then with warm water to extract the benzoic acid formed and the excess of anhydride, and then dried. To the mixture cold ether is now added, in which the benzoate of the amorphous alcohol is readily soluble, those of cholesterin and iso-cholesterin dissolving only slightly. The two latter may then be separated by slow recrystallisation from ether and elutriation, cholesterin benzoate crystallising in plates, and iso-cholesterin benzoate in needles. The benzoates are then separately saponified for their respective cholesterins, which are recrystallised for further purification (E. Schulze, *J. pr.* 7, 163).—4. On adding ether and HCl to fresh oxen bile, the cholesterin is obtained in the ethereal layer (Hüfner, *J. pr.* [2] 19, 305).

Properties.—Monatomic alcohol. Laminated transparent crystals of $C_{26}H_{44}O$,aq (from a mixture of alcohol (2 vols.) and ether (1 vol.)), which give off their water at 100°. Plates (containing aq) (from alcohol and ether). Anhydrous needles (from chloroform). Tasteless and inodorous. Insol. water, v. sol. hot, sl. sol. cold, alcohol, v. sol. ether, chloroform, carbon bisulphide, oil of turpentine, soap water, and neutral fats, &c.

Reactions.—(*a*) Sublimes at 200°, but decomposes at a higher temperature. (*b*) Resists the action of conc. alkaline solutions, even at the boiling temperature, but is decomposed by lime at about 250°, with evolution of hydrogen and formation of an amorphous body nearly insoluble in alcohol. (*c*) For the action of halogens *v.* Derivatives. (*d*) Yields with conc. H_2SO_4 a. b. and c. Cholesterilins (*v.* these) (Zwenger). (*e*) Yields with conc. H_3PO_4 (α) and (β) Cholesterones (*q.v.*).

Characteristic tests. — (*a*) When a few centigrammes are dissolved in chloroform and the solution is shaken up with an equal volume of H_2SO_4 (best of 1·76 S.G.), the chloroform layer, at first yellow-brown, soon becomes blood-red, and then cherry-red or purple, the colour remaining for some hours if the solution is in a closed bottle, *i.e.* if air be not admitted; it then becomes blue, green, and finally yellow. The sulphuric acid at the same time shows a fine green fluorescence (Hesse, *A.* 211, 283; Reinke a. Rodewald, *A.* 207, 229; Salkowski, *C. C.* 1873). (*b*) When a small quantity is evaporated at a gentle heat with a drop of nitric acid, a yellow spot is left, which turns red when touched with a drop of ammonia, and the red colour thus produced is not essentially altered by subsequent addition of fixed alkali, thus distinguishing this from the corresponding reaction with uric acid (Schiff, *A.* 115, 113). (*c*) When slowly evaporated to dryness with 3 vols. conc. HCl or H_2SO_4 and 1 vol. Fe_2Cl_6 solution, the particles remaining undissolved assume a violet-red colour, changing to bluish-violet at a somewhat higher, and dull-grey at a still higher, temperature. This reaction, which is likewise produced with $AuCl_3$, $PtCl_4$, or $K_2Cr_2O_7 + HCl$, is not exhibited by the colouring matter or any other constituent of the bile (Schiff).

Applications.—Cholesterin possesses the property of absorbing more than 100 p.c. of water (Liebrich, *cf. C. S. I.* 5, 578), a point of great therapeutic moment. The grease of sheep's wool is now therefore being purified in quantity, and the manufactured product, which is termed 'lanolin,' used as a basis for ointments, &c.

---

[2] This amorphous alcohol, which is poorer in carbon than cholesterin, is v. sol. cold alcohol, ether, and acetone, but it has not yet been obtained pure, in fact there is as yet no guarantee that it is a chemically simple substance. It has a weak, aromatic odour, and melts at a gentle heat. It appears to be present in the fat, partly free and partly combined with acids, chiefly oleic. The greater portion of wool-fat consists of compound ethers, but a portion of the alcohols—at least of the cholesterins—and also sometimes a portion of the acids are present in the free state. The formation of potash soaps in wool-fat is now readily explained by the presence of free fatty acids on which the K_2CO_3 can act; a portion of the compound ethers may, however, be decomposed also (Schulze a. Urich, *J. pr.* [2] 9, 221).

Cholesteryl chloride, $C_{26}H_{43}Cl$. [97°, Walitzky]. [96°, Raymann]. Prepared by the action of PCl_5 on cholesterin or its acetate. Small scales, sl. sol. alcohol, v. sol. ether. Not decomposed by aqueous, but by boiling alcoholic potash (Planer, *A.* 118, 25; Lindenmeyer, *J. pr.* 90, 321; Rayman, *Bl.* [2] 47, 898).

Cholesterin dibromide $C_{26}H_{44}OBr_2$. Prepared by the action of bromine on cholesterin, both dissolved in CS_2. White needles (from ether-alcohol), sl. sol. alcohol, v. sol. ether. Is reconverted to cholesterin by Na amalgam (Wislicenus a. Moldenhauer, *A.* 146, 175).

Cholesteryl chloro-dibromide $C_{26}H_{43}Cl,Br_2$. [128°]. Prepared by gradually adding Br to an ethereal solution of cholesteryl chloride. White powder or large colourless crystals (from CS_2). Sol. carbon bisulphide, chloroform, and ligroin (Rayman).

Nitro-cholesterin [94°]. Red-yellow mass, insol. water, sol. NH_3Aq and K(Na)OHAq, v. sol. alcohol, ether, chloroform, &c. (Reinitzer, *M.* 9, 421).

Di-nitro-cholesterin $C_{26}H_{42}(NO_2)_2O$ or $C_{25}H_{40}(NO_2)_2O$. [121°]. Colourless needles (from alcohol). V. sol. hot alcohol and ether (Preis a. Rayman, *B.* 12, 224).

Nitro-cholesteryl chloride $C_{26}H_{42}(NO_2)Cl$ or $C_{25}H_{40}(NO_2)Cl$. [149°]. Colourless needles (from alcohol) (P. a. R.).

Cholesteryl acetate $C_{26}H_{43}O.C_2H_3O$ or $C_{27}H_{45}O.C_2H_3O$. [92°, Löbisch, *B.* 5, 513]; [113°, Raymann, *Bl.* 47] [111°–112° uncor. (chol. from gallstones), Jacobsen]; [114·5° cor.] (from gallstones) (Reinitzer, *M.* 9, 428).

Preparation.—By heating cholesterin, also sodium cholesterate, with acetic anhydride, or with acetic acid or acetyl chloride. Needles (from benzene). Trimorphous, the first modification being monosymmetric crystals, and the second monosymmetric plates with rhombic edges, while the third form has not yet been defined. Shows curious changes of colour on solidifying after fusion, which changes are not yet explained, but are apparently closely connected with the separation—during fusion—and resolution of a substance whose nature is not known (Leymann *v.* Reinitzer, *loc. cit.*).

Bromo-cholesteryl acetate $C_{27}H_{45}Br_2.C_2H_3O_2$. [118° cor. and 116° cor.] (Reinitzer, *M.* 9, 424).

Long glancing tables (from ether-alcohol). Dimorphous, the first modification being monosymmetric tables [118°], and the second asymmetric tables [116°]. Somewhat decomposed by light (Reinitzer).

Cholesteryl butyrate $C_{26}H_{43}O.C_4H_7O$. M. sol. hot alcohol.

Cholesteryl stearate $C_{26}H_{43}O.C_{18}H_{35}O$. Needles, sl. sol. cold ether, almost insol. alcohol (Berthelot).

Cholesteryl benzoate $C_{26}H_{43}O.C_7H_5O$ or $C_{27}H_{45}O.C_7H_5O$. [150°–151° Schulze; 146·6° cor. Reinitzer].

Preparation.—See separation of cholesterin and isocholesterin (Schulze, *J. pr.*). Better, by heating anhydrous cholesterin (10 pts.) with benzoic anhydride (12 pts.) in an open flask to 150°–160° for 1½ hours (Reinitzer, *M.* 9). Beautiful small glancing tables (from ether); m. sol. ether, sl. sol. boiling alcohol (Berthelot, Schulze). Trimorphous, the first modification being tetragonal crystals, the second forming rhombic needles or small plates, and the third crystallising in thin broad plates. Exhibits on fusion colour phenomena similar to those shown by the acetate, but not quite the same (Reinitzer, *loc. cit.*).

Sodium cholesterate $C_{26}H_{43}NaO$. [150°].

Formation.—By the action of Na on a saturated solution of cholesterin in petroleum. Silky needles (from petroleum or chloroform). Slowly decomposed by water, more quickly by alcohol (Lindenmeyer, *J. pr.* 90, 321).

Cholesterylamine $C_{26}H_{43}NH_2$. [104°] (Henry). Small plates.

Cholesteryl-aniline $C_{25}H_{41}.C_6H_5NH$. [187°].

Preparation.—By heating cholesterin chloride and aniline to 180° for 6–12 hours (Walitzky, *Chem. Sect. d. Russ. phys.-chem. Ges.*, Oct. 1878; *B.* 11, 1937). Long rectangular plates (from CS_2); m. sol. ether and boiling alcohol, v. sol. carbon bisulphide. Ppd. from ethereal solution by mineral acids.

Salts.—The H_2SO_4, HNO_3, and HCl salts are crystalline.

Cholesteryl-*p*-toluidine $C_{25}H_{41}NHC_7H_7$. [172°]. Prepared at 150°–180°. Rectangular tables (from ether). Sol. alcohol, ether, and carbon bisulphide. Weak base (Walitzky).

Salts.—The HNO_3 salt is much more stable than those of HCl or H_2SO_4.

Tri-oxy-cholesterin $C_{25}H_{42}O_3$.

Preparation.—(*a*) By saponifying the diacetin (see below) with alcoholic potash, dissolving the residue in water and ppg. by an acid (Latschinoff, *Chem. Sect. d. Russ. phys.-chem. Ges.*, Oct. 1878; *B.* 11, 1941).

(*b*) By oxidising a solution of cholesterin in HOAc by $KMnO_4$; this latter method does not yield it quite pure.

Properties.—Yellowish powder. Sol. alcohol, ether, and KOHAq. Mol. w. not yet determined. Resembles phenol in behaviour.

Di-acetyl derivative $C_{25}H_{40}O(C_2H_3O_2)_2$. [77°].

Preparation.—Cholesterin acetate is oxidised by $KMnO_4$ and the di-acetin dissolved out of the resulting mass by ether (Latschinoff).

Properties.—White hard powder, indistinctly crystalline, obtained on adding water to the HOAc solution. V. sol. glacial acetic acid, alcohol, ether, benzene, &c., but not crystallisable from any one of these.

Cholesteriline *a*, *b*, and *c* $C_{26}H_{42}$ or $C_{25}H_{40}$ (Zwenger, *A.* 66, 5; 69, 347).

Preparation.—By acting with conc. H_2SO_4 on a slightly heated mixture of cholesterin and dilute sulphuric acid.

Properties.—(*a*) [240°]. Amorphous. Insol. water, almost insol. alcohol, v. sl. sol. ether. (*b*) [255°] shining scales. Insol. water, m. sol. hot ether. (*c*) [127°]. Resinous. Insol. water, sol. hot ether.

Walitzky's *Cholestene* $C_{26}H_{42}$, obtained by heating cholesterin with sodium to 150°–155°, appears to be identical with *c*, also with the compound obtained by acting on cholesterin with HI (S.G. 1·5), or by heating it with soda-lime up to 250°. Cholestene and the two last give, with excess of Br, the same compound $C_{26}H_{34}Br_8$ (Walitzky, *C. R.* 92, 195).

T. Weyl (*Archiv f. Anat. und Physiol.* 1, 182) has studied these compounds anew, and considers that they agree with the formula $(C_5H_8)_nH_2O$. For the relations between cholesterin, cholalic acid, and the terpenes, see Latschinoff, Walitzky, and Weyl.

Cholesterones $C_{26}H_{42}$ or $C_{25}H_{40}$. When cholesterin is boiled with excess of conc. phosphoric acid it forms two compounds, α- and β-cholesterone, isomeric with each other, but differing in physical properties (Zwenger, *A.* 69, 347).

α-Chloresterone. [68°]. Rectangular prisms, v. sol. alcohol and ether, and distilling without decomposition.

β-Cholesterone [175°]. Small silky needles, almost insol. alcohol, sl. sol. ether.

Cholesteric acid $C_{12}H_{16}O_7$.

Formation.—By the oxidation of cholic acid $C_{24}H_{40}O_5$ or $(C_{24}H_{40}O_5)_x$, by $K_2Cr_2O_7$ (10 parts) and H_2SO_4 (15 parts). The acid must be diluted with at least three times its volume of water before the oxidation, and the latter interrupted as soon as the cholesteric acid is formed, otherwise it is obtained mixed with pyro-cholesteric acid (see below). Redtenbacher's cholesteric acid $C_{16}H_{20}O_6$ (*A.* 57, 160) is such a mixture. The filtered solution must be concentrated at a low temperature, unless the H_2SO_4 is first neutralised. The cholesteric acid crystallises, and is purified either by washing with a little cold water or by recrystallisation from ether (Tappeiner, *A.* 194, 211; *B.* 12, 1627; Latschinoff, *B.* 12, 1518).

Properties.—Tribasic acid. Needles (from water and alcohol), long prisms (from ether containing some water). V. sol. hot water. Not volatile with steam. Slightly dextro-rotatory in alcoholic solution. Gives no colouration with sugar and H_2SO_4, and has not the toxic action of cholic acid. Its power of crystallisation is greatly diminished by the presence of small quantities of the pyro-acid.

Salts.—The Ca and Ba salts are less sol. hot than cold water. At 100° they generally go into salts of pyro-cholesteric acid (Tappeiner). A'''_2Ba_3, $A'''Ag_3$, $A'''H_2Ag$.

Pyro-cholesteric acid $C_{11}H_{16}O_5$. [108°].

Preparation.—(*a*) Best by heating a solution of cholesteric acid in glycerin for 5 to 8 days at 198°, saponifying the glycerates, distilling off small quantities of volatile acids, such as propionic, and extracting with ether (Tappeiner). (*b*) Also by boiling with H_2SO_4 diluted with 3 vols. water, but in this case the decomposition goes further.

Properties.—Gummy mass, sol. water, alcohol, and ether.

Iso-cholesterin $C_{26}H_{44}O$. [138°-138·5°]. $[\alpha]_D$ in ethereal solution + 60° (Schulze, *J. pr.* [2] 7, 163; Schulze a. Urich, *J. Pr.* [2] 9, 321; Schulze, *B.* 12, 249).

Occurrence.—In the fat of sheep's wool.

For *Preparation* and separation from cholesterin, see the latter.

Properties.—Flocks (from dilute alcoholic solution), a jelly (from concentrated alcoholic solution), fine transparent needles (from ether or acetone). Sl. sol. cold, v. sol. hot, alcohol, ether, and acetone, *i.e.* solubility is very much the same as that of cholesterin. A mixture of cholesterin and iso-cholesterin melts at a lower temperature than either separately.

Reactions.—(*a*) The $CHCl_3$ and H_2SO_4 test gives only a very feeble colouration (Schulze, *J. pr.* [2] 7, 163). (*b*) The HNO_3 and NH_3 test gives the same colouration as cholesterin.

Iso-cholesterin derivatives.

Iso-cholesteryl chloride $C_{26}H_{43}Cl$. Prepared by the action of PCl_5 on iso-cholesterin. Amorphous. V. sol. ether, sl. sol. alcohol.

Acetyl derivative [below 100°]. Amorphous; sl. sol. alcohol.

Stearyl derivative [72°]. Fine white needles (from ether). V. sl. sol. alcohol.

Benzoyl derivative $C_{26}H_{43}O.C_7H_5O$. [190°-191°]. Fine needles (from ether). Sl. sol. alcohol, m. sol. acetone, v. sol. ether.

Phytosterin $C_{26}H_{44}O$,aq. [132-133°] (Hesse, *A.* 192); [133°] (v. Lippmann, *B.* 20, 3201); [133°] Paschkis, *H.* 8, 356; [132°], [135°], [133°], and [136°], Jacobsen; [136-137°], Beneke; [136-137°] Schulze a. Barbieri (from lupines), *J. pr.* [2] 25, 159. $[\alpha]_D$ (anhydrous in $CHCl_3$)

= − 34·2° (Hesse)
= − 33·7° and − 35·1° (*v.* Lippmann)
from − 30·4 to − 33·4 (Jacobsen)
− 32·7° (Paschkis)
− 32·5° in ether (Lindenmeyer)
− 36·4° (Schulze a. Barbieri).

Those who first isolated phytosterin considered it to be cholesterin. The name phytosterin was given to it by Hesse.

Occurrence.[1]—In peas and olive oil (Beneke, *A.* 122, 249; Knop, *C. C.* 1862, 819); calabar beans (Hesse, *A.* 192, 176); in the seeds and cotyledons of the shoots of the yellow lupine, '*Lupinus luteus*' (Schulze a. Barbieri, *J. pr.* [2] 25, 159); in almonds; mustard seed; Bockshorn seed; in numerous fungi, *e.g. Polyponis officinalis* (Schmieder, *C. C.* 86, 774); in the seed oil of rape, lentils, almond, cotton, earth nut or pea nut, poppy, and cocoa (Salkowski, *Z. f. Anal. Chem.* 26, 557); together with cholesterin in butter and cod-liver oil (Salkowski); in hog's beans and vetches (Jacobsen); in the juice of beet (v. Lippmann, *B.* 20, 3201); in wheat gluten (Ritthausen, *J. pr.* 85, 212; 88, 145); in maize grains (Hoppe-Seyler, *Krit. Zeit.* 10, 32); in barley fat (Stellwaag, *Zeitschr. f. d. g. Brauwes.* 1886, 176; *Chem. Zt., Chem. Repert.* 10, No. 23); in the fat of meadow hay and of oat straw (König, *Landw. Versuchstationen*, 17, 3, 11); in colchicum seeds (Paschkis, *H.* 8, 356); in the oil of the seeds of Chaulmoogra (*Gynocardia odorata*, Roxb.), of Jéquirity (*Abrus precatorius* Lam.), and in the fat of the leaves of *Erythroxylum hyperificifolium* Lam. (Heckel a. Schlagdenhauffen, *C. R.* 102, 1087); probably also in the animal body, possibly together with cholesterin, as may be deduced from older observations (Gmelin, *Handb.* 4, 2092).

Preparation.—(*a*) From peas (Beneke, *loc. cit.*).

(*b*) From calabar beans. These are extracted with petroleum ether. When this is evaporated, a fatty oil is left, out of which phytosterin crystallises. It is separated from the oil by pressure, purified by dissolving in ether with bone black, and recrystallised from alcohol (Hesse, *A.* 192, 176).

(*c*) From beans. The powdered beans are extracted with alcohol, the alcohol distilled, and the residue extracted with ether. This extract s saponified with 25 p.c. NaOH, and the layer f fat separated from the deep-coloured mother iquor. The fat, purified from glycerin, is then xtracted with ether, and the phytosterin obained from this ether extract (Jacobsen, *Inaug. Dissert.* Königsberg in Preussen, 1887).

---

[1] It is possible that in some of the cases here mentioned a cholesterin other than phytosterin is present.

(*d*) From the powdered seeds and shoots of he yellow lupine (Schulze a. Barbieri, *J. pr.* [2] 25, 159). The finely powdered seeds and shoots are extracted with ether, the extract distilled, and the residue boiled for several hours with alcoholic potash, using a reflux condenser. The solution thus obtained is evaporated, the residue rubbed up with water and shaken with ether several times. The ether is then distilled off, and the residue dissolved in the least possible quantity of hot alcohol. On cooling, the phytosterin crystallises out. It may then be purified by conversion into the benzoate, re-saponification of this with alcoholic potash, and re-crystallisation from alcohol.

(*e*) Reinitzer recommends the following method for the separation of cholesterin from fats (*M.* 7, 597). The juice—*e.g.* of carrots—is ppd. with $PbAc_2$, the pp. dried, and—together with the pressed vegetable—extracted by carbon bisulphide. The residue after distillation of the bisulphide is saponified with alcoholic potash, the alcohol evaporated, the mass taken up with water and ppd. by $BaCl_2$, and the washed and vacuum-dried pp. extracted by acetone.

Properties.—Glittering plates of $C_{26}H_{44}O$aq (from alcohol), silky needles of $C_{26}H_{44}O$ (from chloroform, ether, and petroleum ether). Insol. water or KOHAq, v. sol. hot alcohol, ether, and chloroform. A mixture of phytosterin (from lupines) and cholesterin crystallises from alcohol in a mass of small needles, *i.e.* in a form different from that of either separately.

Reactions.—(*a*) The $CHCl_3$ and H_2SO_4 test gives exactly the same results as with cholesterin and quebrachol (Hesse, *A.* 211, 283).

(*b*) Cautiously evaporated with HCl and Fe_2Cl_6, it gives a violet colour like ordinary cholesterin.

Acetyl derivative $C_{26}H_{43}O(C_2H_3O)$ or $C_{25}H_{41}O(C_2H_3O)$. [120°, Hesse]. [126°, 120°, 118°, and 125° uncor., Jacobsen]. Glancing plates (from alcohol) (Hesse). Resembles in its properties the acetates of cupreol and quebrachol (H.). Prismatic needles (from alcohol) (Jacobsen). Sl. sol. alcohol, v. sol. ether and chloroform.

Benzoyl derivative [145·5°, 147°, 146°, and 145° uncor., Jacobsen]. Thin glancing rectangular plates (from ether), sl. sol. alcohol, m. sol. ether and chloroform. Gives the colour reactions with $CHCl_3$ and H_2SO_4 and with Fe_2Cl_6, but not with HNO_3 and NH_3 (Jacobsen).

Hydrocarotin $C_{26}H_{44}O$aq? [136·5°] $[\alpha]_D$ (in $CHCl_3$) $-85°$ (Arnaud, *C. R.* 102, 1319; also 100, 751). [138·2°]. $[\alpha]_D$ (in $CHCl_3$) $-37·4$ (Reinitzer, *M.* 7, 579). This substance is probably phytosterin, although Reinitzer considers that it more nearly resembles Liebermann's cholestol (oxyquinoterpene) $C_{30}H_{48}O_2$? [139°], which latter, in its turn, Hesse looks on as being probably almost pure cinchol.

Occurrence and preparation.—In and from carrots.

Properties.—Plates (containing aq) (from alcohol), anhydrous needles (from the other solvents). Insol. water, sl. sol. cold, v. sol. hot alcohol, ether, chloroform, &c. Fröhde (*J. pr.* 102, 424) declared hydrocarotin to be cholesterin, which Husemann repudiated. Arnaud, however, finds that Husemann's hydrocarotin (*A.* 117, 200) is phytosterin mixed with some carotene.

Reactions.—Gives the cholesterin reactions with

(*a*) $CHCl_3$ and H_2SO_4
(*b*) HNO_3 and NH_3
(*c*) HCl and Fe_2Cl_6
(*d*) Liebermann's with $(Ac)_2O$ and H_2SO_4 (*B.* 18, 1803).

Acetyl derivatives. [128·2°]. Colourless crystalline scales (from ether-alcohol). Sl. sol. hot alcohol.

Benzoyl derivative. [145°]. Dimetric glancing tables, when slowly crystallised from ether. V. sol. ether. (*Cf.* phytosterin.)

Para-cholesterin $C_{26}H_{44}O$aq. [134°–134·5° uncor., R. a. R.]. $[\alpha]_D$ (in $CHCl_3$) $-28·88$ and $-27·24$ for different strengths (R. a. R.).

Occurrence.—In the protoplasm of *Ethalium septicum.*

Preparation.—*Ethalium septicum* is digested with alcohol and the whole mass evaporated to dryness and extracted with ether. From this the *p*-cholesterin crystallises out, and is purified by crystallisation from hot alcohol, the cholesterin which is also present remaining in the alcoholic mother liquor (Reinke a. Rodewald, *A.* 207, 229).

Properties.—Plates (containing aq) (from alcohol), silky glancing needles (from ether and chloroform). V. sol. hot alcohol, ether, and chloroform, m. sol. cold alcohol. Gives up its water over H_2SO_4. In general properties it agrees with cholesterin, iso-cholesterin, and Beneke's cholesterin from peas, in chemical properties it resembles Hesse's phytosterin.

Reactions.—The $CHCl_3$ and H_2SO_4 test gives much the same colouration as Schulze's iso-cholesterin. At first both the chloroform and sulphuric acid layers are coloured yellowish-brown, the latter with green fluorescence. On prolonged standing the chloroform becomes blue and then violet, while the acid becomes a deeper brown and the fluorescence increases (R. a. R.).

Benzoyl derivative. [127°–128° uncor.]. Thin glancing rectangular plates (from ether). V. sol. ether and chloroform, m. sol. hot, sl. sol. cold, alcohol (R. a. R.).

Caulosterin $C_{26}H_{44}O$aq. [158°–159°]. $[\alpha]_D$ (in chloroform) $-49·6°$.

Occurrence and preparation.—In the root and growing parts (radicles) of the shoots of the yellow lupine, 'lupinus luteus,' from which it is extracted in the same way as the phytosterin from the seeds (Schulze a. Barbieri, *J. pr.* [2] 25, 159].

Reaction.—*a.* With $CHCl_3$ and H_2SO_4 it behaves in the same way as cholesterin and phytosterin.

Benzoyl derivative.—Thin glancing plates (from ether).

It will be seen from the foregoing description of the cholesterins that much investigation is still required to determine whether they are homologues or isomerides.

1. The various animal cholesterins (from biliary calculi, brains, &c.) have hitherto been considered to be one and the same substance, since preparations from many different sources have been found to possess the same melting-point, and also because of the homogeneity of the benzoic ether (Schulze a. Barbieri); but the point still requires further proof (Reinitzer, *M.* 9). It is not impossible that different cholesterins should occur in different animal organs, just as different varieties were found by Schulze and Barbieri in different parts of the yellow lupine (*cf.* Hesse, *A.* 192). For the probable relation of the cholesterins to the terpenes and camphors *v.* Walitzky (*B.* 9, 1310), Latschinoff (*B.* 12, 1518), Liebermann (*B.* 17, 871; 18, 1803), and Weyl (*Archiv f. Anat. u. Physiol.* 1, 182, *B.* 19, *Ref.* 618). The analogy of cholesterin to camphor is confirmed by the absence of any action when it is treated with hydroxylamine (Rayman, *Bl.* 47).

2. Iso-cholesterin is apparently a simple substance.

3. Para-cholesterin differs little from phytosterin, excepting in specific rotatory power, and requires to be further examined.

4. With regard to vegetable cholesterins, Hoppe-Seyler (*Handb. d. physiol. u. pathol. Chem. Analyse*, 4te Aufl. *p.* 110) surmised that cholesterin was probably a constant constituent of meristematic plant cells. Since they are so widely distributed among plants the cholesterins, according to Schulze and Barbieri, are to be looked upon as invariable constituents of the protoplasm. These last-named authors found cholesterins in very considerable quantity in the etiolated shoots, but only in very small quantity in the green plants of the yellow lupine, and hence they concluded that vegetable cholesterins, especially caulosterin, are decomposition products of albuminous compounds in the life process of the cells, a point already suggested by Hoppe-Seyler (*Handb.* 1, 81). Hesse considers that, because normal cholesterin possesses a stronger rotatory power than phytosterin, the former compound must be the next homologue to $C_{26}H_{44}O$ *i.e.* $C_{25}H_{42}O$, the formula proposed by Walitzky, and also at one time by Berthelot (Gmelin, *Handb. d. Org. Chem.* 4, 2093), although the latter returned later on to the one usually accepted, viz. $C_{26}H_{44}O$; Reinke and Rodewald, however, think this insufficient to overthrow the theory of the isomerism of the cholesterins. Cupreol, cinchol, and quebrachol (all of them $C_{20}H_{34}O,H_2O$), and also Liebermann's cholestol (which is believed by Hesse to be nearly pure cinchol), all belong to this class of cholesterins. Reinitzer is of opinion that cynancocerin, cynanchin, echicerin, and echitine (Hesse, *A.* 192, 182), aspidol (Daccomo, *Centralbl.* 87, 1357), ambrain, castorin, &c., must also be included, and that the cholesterins will ultimately be found to be divisible into two homologous groups, dextro- and lævo-rotatory. For the latest discussion on this point, *v.* Reinitzer (*M.* 9). G. M.

CHOLESTROPHANE *v. Di-methyl*-PARABANIC ACID.

CHOLIC ACID $C_{24}H_{40}O_5$ *i.e.* $C_{20}H_{31}(CH.OH)(CH_2.OH)_2CO_2H$ (?). *Cholalic acid.* [195°]. S. (of anhydrous crystals) 133 at 100°; ·025 at 15°.

Formation.—By the hydrolytic action of alkalis on glycocholic and taurocholic acids, which occur in the bile (Demarçay, *A. Ch.* [2] 67, 177; Theyer a. Schlösser, *A.* 48, 77; 50, 235; Strecker, *A.* 65, 9; 67, 1; 70, 161, 166).

Preparation.—Glycocholic acid (50 grms.) is boiled for 16 hours with water (6 litres) and baryta (200 grms.). The liquid is filtered hot and, when cold, HCl added. A sandy pp. of cholic acid falls. Crystallised from alcohol. The yield is 80 p.c. (Hartmann, *J. pr.* [2] 19, 307; *cf.* Tappeiner, *A.* 194, 213).

Properties.—Crystallises from hot water in anhydrous microscopic crystals, from cold solutions, *e.g.* very dilute acetic acid, in trimetric tables (containing aq). The acid combines with methyl-, ethyl-, propyl-, and ethylene-alcohols and with mustard oils, but not with acetone. The hydrated and anhydrous acid and its various alcoholates all crystallise in the trimetric system, the axis-ratio *a:c* remains constant whilst *b:c* varies in the different alcoholates. Gives a blood-red colour with cane sugar and H_2SO_4 (Pettenkofer's test, *v.* BILE).

Reactions.—1. By gentle *oxidation* with acetic acid and CrO_3 it yields dehydrocholic acid $C_{24}H_{34}O_5$, probably $C_{20}H_{31}(CO)(CHO)_2CO_2H$; by more vigorous oxidation with $K_2Cr_2O_7$ and H_2SO_4, bilianic acid $C_{24}H_{34}O_8$ is formed (but no cholanic acid) (*cf.* Destrem, *C. R.* 87, 880; Clève, *C. R.* 91, 1073).—2. By *putrefactive fermentation* it is reduced to desoxycholic acid $C_{24}H_{40}O_4$. The latter acid probably accompanies cholic and choleic acids in saponified ox-gall.—3. Combines with *iodine* and HI or other metallic iodides to form unstable blue compounds $(A'H)_4MI_5$ which greatly resemble iodide of starch in properties.—$(A'H)_4HI_5$ *x*aq: formed by adding iodine and HI to an alcoholic solution of cholic acid.—$(A'H)_4KI_5$ *x*aq: formed by adding iodine and KI to an alcoholic solution of cholic acid. Small bronzy needles, which suspended in water form an indigo-blue liquid. Readily decomposed into its constituents by heat, great dilution with water, alkalis, &c.—$(A'H)_8BaI_{10}$ *x*aq: like the preceding compounds (Mylius, *B.* 20, 683).

Mono-acetyl derivative $C_{24}H_{39}(OAc)O_4$: formed by passing HCl gas through an acetic acid solution of cholic acid. Amorphous powder. V. e. sol. alcohol, ether, benzene, &c.

Di-acetyl derivative $C_{24}H_{38}(OAc)_2O_3$: formed by allowing cholic acid to stand with cold acetic anhydride till it dissolves. White granular crystalline powder. V. sol. alcohol, ether, benzene, &c., insol. water. Bitter taste. Its Ba salt is insol. water (Latschinoff, *Bl.* [2] 33, 297; *B.* 18, 3039; 20, 1043; Mylius, *B.* 19, 869, 2000; 20, 1968). Schotten (*H.* 11, 268) denies the existence of acetyl derivatives of cholic acid.

Amide $C_{24}H_{39}O_4.NH_2$. Formed by heating the acid with alcoholic NH_3 at 250°. Small crystals (containing 3aq). Sl. sol. water. The hydrated compound melts at [125°–130°]. The anhydrous compound melts slowly from [130°–140°], again solidifies at about 180° to a colourless crystalline mass, which again melts at [c. 228°]; if this crystalline mass is crystallised from alcohol, nothing is obtained but the ordinary amide.

Di-methyl-amide $C_{24}H_{39}O_4.NMe_2$. [171°]. Formed by heating the acid with aqueous dimethylamine at 250°.

Anhydrides.—By heating cholic acid under various conditions mixtures of various anhydrides have been obtained, none of which have been isolated in a pure state (Mylius, *B.* 20, 1968).

Ethyl ether $C_{24}H_{39}EtO_5$. [147°].

Preparation.—Cholic acid (20 pts.) is dissolved in dilute (90 p.c.) alcohol (140 pts.) and the solution saturated, in the cold, with dry HCl. An equal volume of alcohol is at once added and every 100 c.c. of the liquid poured in a thin stream into a litre of water. After a few days, needles of the ether appear (Tappeiner; Hartmann).

Dehydrocholic acid $C_{24}H_{34}O_5$ probably $C_{20}H_{31}(CO)(CHO)_2CO_2H$. [232°] (M.). [228° uncor.] (L.). Formed by slowly adding a 10 p.c. solution of CrO_3 (9 pts.) in acetic acid, to a 10 p.c. solution of cholic acid (10 pts.) in acetic acid. Anhydrous needles. By further oxidation with $K_2Cr_2O_7$ and H_2SO_4 it is converted into bilianic acid $C_{24}H_{34}O_8$ *i.e.* $C_{19}H_{31}(CO)_2(CO_2H)_3$. It does not give Pettenkofer's bile reaction.

Tri-oxim $C_{24}H_{34}(NOH)_3O_2$: formed by the action of a cold solution of hydroxylamine upon sodium dehydrocholate. Colourless microscopic tables. Sl. sol. hot alcohol, nearly insol. water and ether. Stable in alkaline solution, but resolved into its components by acids (Latschinoff, *B.* 18, 3045; Mylius, *B.* 19, 2005; 20, 1979).

Phenyl-mercaptide $C_{24}H_{34}O_4(SC_6H_5)_2$: [c. 220°]; colourless glistening needles; sl. sol. water. Formed by passing HCl through a cold solution of the acid in phenyl-mercaptan. The sodium salt forms fine needles, insol. water.

Phenyl-mercaptide-phenyl-hydrazide $C_{23}H_{33}(SC_6H_5)_2(N_2HC_6H_5)_2CO_2H$: separates in colourless needles on warming an acetic acid solution of the phenyl-mercaptide with phenylhydrazine (Mylius, *B.* 20, 1979).

Desoxy-cholic acid (probably identical with the so-called '*hydrated choleic acid*' of Latschinoff) $C_{24}H_{40}O_4$ (M.) or $C_{25}H_{42}O_4$ 1½aq (L.). [135°–140°] (L.); [160°–170°] (M.). Large dimetric crystals, $a{:}a{:}c = 1{:}1{:}2·4828$ (L.). White needles, v. sol. alcohol, sl. sol. acetic acid (M.). Occurs, together with cholic and choleic acids, in saponified ox-gall (L.). Formed by putrefactive fermentation of cholic acid (M.). According to L. it is formed in small quantity by boiling choleic acid with acetic acid, but M. was unable to effect this conversion. By gentle oxidation with CrO_3 and acetic acid it is converted into dehydrocholeic acid; by more vigorous oxidation with $K_2Cr_2O_7$ and H_2SO_4 into cholanic acid (L.) (Latschinoff, *B.* 18, 3041; 20, 1043; Mylius, *B.* 19, 373; 20, 1968).

The observations marked (L.) refer to Latschinoff's hydrated choleïc acid, those marked (M.) relate to the desoxycholic acid of Mylius.

CHOLINE *v.* Neurine.

CHOLOÏDANIC ACID $C_{25}H_{38}O_{11}$ *i.e.* $C_{20}H_{33}O(CO_2H)_5$ (?). *Cholecamphoric acid.* S. ·015 at 18°; ·18 at 100°. $[\alpha]_D$ 57° 56′. Formed, together with pseudo-choloïdanic acid, by boiling cholanic acid (1 g.) with HNO_3 (30 c.c. of S.G. 1·28) for several hours. Formed also by the action of HNO_3 on bile (Theyer a. Schlösser, *A.* 50, 243) or cholic acid (Redtenbacher, *A.* 57, 145; Tappeiner, *A.* 194, 239; Clève, *Bl.* [2] 38, 135).

Salts.—A^vAg_5 4aq: gelatinous pp.—$A^v_2Pb_5$: amorphous pp.—$A^v_2Ba_5$ 20aq: thick prismatic crystals, S. (at 18°) about 20 (Latschinoff, *B.* 13, 1052; 19, 1521).

Pseudo-choloïdanic acid $C_{50}H_{71}O_{21}$(?). Formed, together with choloïdanic acid, by boiling cholanic acid (1 g.) with HNO_3 (30 c.c. of S.G. 1·28) for several hours. Microscopic needles.

Salts. — $A^{viii}H_4Ba_2$ 20aq: flat needles.—$A^{viii}Ag_8$: amorphous pp.

Ethyl derivative $C_{50}H_{70}(C_2H_5)_4O_{21}$: [247°]. Obtained by the action of EtI upon the lead salt. Needles. V. sol. alcohol, less in ether.—$C_{50}H_{66}Et_4O_{21}Ba_2$ 2aq: prisms.

Methyl derivative $C_{50}H_{70}(CH_3)_4O_{21}$: [194°–196°]; needles.

Neutral methyl ether $C_{50}H_{66}(CH_3)_8O_{21}$: [128°]. Obtained by the action of ethyl iodide upon the silver salt. Flat needles (from alcohol) (Latschinoff, *B.* 19, 1521; *cf.* Clève, *Bl.* [2] 38, 135).

CHONDRIN *v.* Proteïds, *appendix C.*

CHROMITES, Salts of the form $MO.Cr_2O_3$; *v.* Chromium, acids of, p. 158.

CHROMIUM Cr. At. w. 52·45. Mol. w. unknown. [Above M. P. of Pt which is about 2500°] (Deville, *A.Ch.* [3] 46, 182). S.G. 6·5–6·8 (Wöhler, *A.* 111, 230; Loughlin, *Am. S.* [2] 45, 131; Rammelsberg, *Handbuch d. krystallog. u. physikal. Chemie*, part 1 [1881]). S.H. (22°–50°) ·0998 (uncertain) (Kopp, *T.* 155, 71). S.V.S. about 7·8.

Occurrence.—Never free: chiefly as oxide in combination with FeO as *chrome-ironstone*, $FeO.Cr_2O_3$, with Cr_2O_3 more or less replaced by Fe_2O_3 and Al_2O_3, and FeO by MgO. Also as basic chromate of lead, as chromic oxide, &c. The ores of Cr are not very widely distributed. Chromium was discovered by Vauquelin in 1797; the name was given (χρῶμα) because of the number of compounds of different colours obtained from the metal.

Preparation.—Chrome ironstone is separated from gangue, finely powdered, washed, mixed with CaO and KHO, dried at 150°, and heated to bright redness in contact with air, the mass being constantly stirred; after cooling, the K_2CrO_4 formed is dissolved out in a little warm H_2O, enough conc. H_2SO_4 to convert all the K_2CrO_4 into $K_2Cr_2O_7$ is added, and the $K_2Cr_2O_7$ which separates is re-crystallised from hot H_2O. The $K_2Cr_2O_7$ is heated with S, or starch, or NH_4Cl, and the product washed with H_2O, in which the Cr_2O_3 formed remains undissolved (*v.* Chromic oxide, p. 164). Cr_2O_3 is then mixed with rather less charcoal than is theoretically required for complete reduction, and heated to a very high temperature in a lime crucible. Or, Cr_2O_3 is mixed with charcoal, and heated in Cl whereby $CrCl_3$ (*q.v.*) is obtained; the $CrCl_3$ is then heated to bright redness, and H carrying with it Na vapour is passed over it; monometric crystals of Cr are thus obtained (Fremy, *C. R.* 44, 632). Wöhler (*A.* 111, 230) mixes 1 part violet $CrCl_3$ with 2 parts of a fused and powdered mixture of 7 parts NaCl and 9 parts KCl, presses the mixture firmly into a crucible, and places 2 parts granulated Zn over it, and more NaCl and KCl over this again; he gradually heats until the mass is melted. As soon as the Zn boils, and the flame of burning Zn is seen on removing the crucible, the temperature is decreased, and the mass is kept just melted for 10 minutes. The whole is then allowed to cool, the crucible being shaken once or twice; the crucible is broken, the zinc regulus dissolved in dilute HNO_3Aq, the metallic Cr then boiled once with HNO_3Aq, washed, and dried. Zettnow prepares $CrCl_3$ solution by reducing $K_2Cr_2O_7$ in HClAq by C_2H_6O, adds KCl, evaporates to dryness, and reduces by Zn as already described (*P.* 143, 477). According to Bunsen (*P.* 91, 619) Cr may be obtained in lustrous plates by electrolysing an acid solution of $CrCl_2$ containing $CrCl_3$. Vincent (*P. M.* [4] 24, 328) and Roussin (*J. Ph.* [4] 3, 413) form an amalgam of Cr, by acting on solution of a chromic salt by Na amalgam, and heat this in H or vapour of rock-oil.

Properties.—Descriptions of properties of Cr vary considerably. The metal obtained by reducing $CrCl_3$ by Na vapour, or by reducing Cr_2O_3 by C, is described (Fremy, *C. R.* 44, 632) as unchanged by heating in air, in *aqua regia* or HFAq, or by fusing with KOH or KNO_3. The metal obtained by electrolysis (Bunsen, *P.* 91, 619), or by reducing $CrCl_3$ by Zn (Wöhler, *A.* 111, 230), is oxidised by molten KNO_3 or $KClO_3$, and is dissolved in hot dilute HClAq or H_2SO_4Aq. Berzelius (*A.* 49, 247) supposed that Cr existed in two distinct forms. The metal insoluble in *aqua regia* probably contained Si derived from the vessels. According to Bunsen and Wöhler, Cr is a greyish-white powder, consisting of small, lustrous, very hard, brittle, rhombohedral crystals (dimetric octahedra, Bolley, *C. J.* 13, 333); only superficially oxidised, unless in very fine powder, by heating in air; slowly oxidised by heating to redness in steam; burns brightly when heated in an alcohol flame fed with O; oxidised by molten $KClO_3$ or KNO_3, but not by molten Na_2CO_3; dilute HClAq, or hot dilute H_2SO_4Aq, dissolves it readily with evolution of H; scarcely acted on by hot conc. HNO_3Aq; burns in Cl gas forming violet $CrCl_3$. Cr is less fusible than Pt (Deville, *A. Ch.* [3] 46, 182). It is not magnetic (Wöhler, *A.* 111, 230); slightly magnetic (Faraday).

The atomic weight of Cr has been determined (1) by analysing and determining V.D. of CrO_2Cl_2 and $CrCl_3$; (2) by measuring the S.H. of Cr; (3) by analyses, and comparison with other analogous compounds, of $CrCl_2$ (Péligot, *A. Ch.* [3] 12, 530); Ag_2CrO_4 and $Ag_2Cr_2O_7$ (Berlin, *A.* 56, 207); $Cr_2(NH_4)_2(SO_4)_4.24H_2O$ (Moberg, *J. pr.* 43, 114); $CrCl_3$ (Siewert, *J.* 1861. 241); by synthesis of $BaCrO_4$ from $BaCl_2$ (Wildenstein, *J. pr.* 59, 27); by oxidising $FeCl_2$Aq by $K_2Cr_2O_7$ and by $KClO_3$, and by oxidising As_4O_6Aq by $K_2Cr_2O_7$ (Kessler, *P.* 95, 210); (4) by comparing chromates with isomorphous manganates and tellurates. The atom of Cr is trivalent in the gaseous molecule $CrCl_3$ (Scott, *Pr. E.* 14, 410) (*v.* Chromium hexafluoride, under Chromium, fluorides of, p. 162).

Chromium is both metallic and non-metallic; Cr replaces the H of most acids forming two series of salts, the simplest formulæ for which are CrX_2 and CrX_3, respectively, where $X = Cl_2$ &c., NO_3 &c., $\frac{SO_4}{2}$ &c., $\frac{PO_4}{3}$ &c.; the chromous salts, CrX_2, are very unstable, and are easily oxidised to chromic salts, CrX_3. Many basic chromic salts are known. The oxide Cr_2O_3 is basic towards acids, and at the same time exhibits feebly acidic properties; CrO_2 seems to be a neutral oxide and not to form salts either by the action of acids or alkalis; CrO_3 is distinctly an anhydride. CrO_3Aq behaves as a dibasic acid, forming a series of salts M_2CrO_4, the acid H_2CrO_4 has also been obtained. Although no salts of the form $MHCrO_4$ are known as definite solids, yet the thermal reactions of CrO_3Aq point to the formation of these salts; thus (*Th.* 1, 254)

n	[CrO^3Aq, n NaOHAq]
1	13,134
2	24,720
4	25,164.

By the action of acids on M_2CrO_4, dichromates, $M_2Cr_2O_7$, are formed: a few tri- and tetra- chromates, $M_2Cr_3O_{10}$ and $M_2Cr_4O_{13}$, are known. CrO_3 also reacts with strong acids to form chromic salts and O; it combines directly with a few anhydrides, *e.g.* with SO_3. Chromic oxide, Cr_2O_3, reacts towards acids as a salt-forming oxide, but at the same time it combines with some of the more positive metallic oxides, *e.g.* with CaO, MnO, ZnO. Several hydroxides of Cr, or perhaps rather hydrated oxides, are known, derived from the oxide Cr_2O_3, and the lower oxide CrO which has not itself been obtained free from Cr_2O_3; these hydrates are salt-forming in their reactions with acids. The pps. produced by adding KOHAq or NaOHAq to solutions of chromic salts always contain potash or soda which cannot be removed by washing with hot water. Cr_2S_3 exhibits slight salt-forming properties in its reactions towards sulphides of more positive metals; no hydrosulphide of Cr is known. Chromium is closely related to Mo, W, and U; less closely to S, Se, and Te; it also shows distinct relations to Al, Mn, and Fe (*v.* Chromites; Chromium group of elements; also Chromium, salts of; Chromates; and the arts. on Hydroxides, Oxides, Chlorides, &c. of Chromium).

Reactions.—1. Decomposes *steam* at bright red heat.—2. Dissolves in *hydrochloric* and *sulphuric acids*, forming salts and H.—3. Oxidised by molten *potassium nitrate* or *chlorate.*—4. Burns when heated in *chlorine*, forming $CrCl_3$. 5. Is oxidised by strongly heating in *oxygen.*—6. Forms CrN by heating in *nitrogen*, and Cr_2S_3 by heating with *sulphur.*

Combinations.—Most of the compounds of Cr are obtained directly or indirectly from the oxides. The metal combines directly with Cl, N, O, and S. Compounds of Cr with each of the non-metals, except H, B, Si, and Te, are known; alloys with Al, Fe, and Hg, have been prepared

(v. the various binary compounds of Cr, also CHROMIUM, ALLOYS OF).

Estimation.—Chromium may be estimated in the form of oxide Cr_2O_3, after ppn. by NH_3Aq from a warm solution. Chromates are usually estimated as $BaCrO_4$, or they may be ppd. by $HgNO_3Aq$, and the Hg_2CrO_4 heated until only Cr_2O_3 remains; or the chromate may be reduced, by alcohol, to a chromic salt, and the Cr determined by ppn. with NH_3Aq &c. Cr may be separated from many heavy metals by ppg. these metals as sulphides, by H_2S; Ba and Sr are best separated by ppn. with H_2SO_4Aq; separation from Ca, Mg, and Fe, is effected by ppg. $Cr_2O_3.xH_2O$ by NH_3Aq, collecting, drying, and fusing with KNO_3 and K_2CO_3 until all the Cr exists as K_2CrO_4, dissolving in water and ppg. as Hg_2CrO_4 or $BaCrO_4$. If alumina is present, it is ppd. from the solution containing K_2CrO_4 by digesting with ammonium carbonate. $Cr_2O_3xH_2O$ is ppd. by digesting solutions of chromic salts with excess of $BaCO_3$; under the same conditions salts of Ni, Co, Mn, and Zn, are not ppd.

Chromium, acids of, and their salts (comp. arts. ACIDS; ACIDS, BASICITY OF; HYDROXIDES). Chromic acid H_2CrO_4 is said to have been obtained in definite form, by the action of H_2O on the anhydride CrO_3 (*v. infra*, CHROMIC ACID). This acid forms a series of chromates, M_2CrO_4, isomorphous with M_2SO_4. H_2CrO_4Aq reacts as a dibasic acid (*v. infra*, CHROMIC ACID); no salts of the form $MHCrO_4$, but only the salts M_2CrO_4, have been obtained by neutralising the acid by alkalis; when acids react with chromates of monovalent metals M_2CrO_4, two formula-weights of the chromate usually react with one formula-weight of a dibasic acid (*e.g.* H_2SO_4), half of M is removed, and a *dichromate*, $M_2Cr_2O_7$—similar to the disulphates $M_2S_2O_7$—is produced. Several *trichromates* $M_2Cr_3O_{10}$, and *tetrachromates* $M_2Cr_4O_{13}$, are also known; these salts are probably best regarded as derived from $M_2Cr_2O_7$ and M_2CrO_4, and from $2M_2Cr_2O_7$, respectively, by the removal of half the total M and condensation of the residues. The following formulæ express this view of the constitution of the di-, tri-, and tetra-, chromates:

(1) *Chromic acid*, $CrO_2(OH)_2$;
(2) *Chromates*, $CrO_2(OM)_2$;
(3) *Dichromates*, $OM.CrO_2.O.CrO_2.OM$;
(4) *Trichromates*, $OM.CrO_2.O.CrO_2.O.CrO_2.OM$;
(5) *Tetrachromates*,
$OM.CrO_2.O.CrO_2.O.CrO_2.O.CrO_2.OM$.

These various series of salts may also be regarded as direct compounds of metallic oxide with CrO_3 ($M_2O.CrO_3$; $M_2O.2CrO_3$; $M_2O.3CrO_3$; $M_2O.4CrO_3$). Besides these salts, several basic chromates are known (*v. infra*). Chromic acid, H_2CrO_4, being dibasic, and forming M_2CrO_4 analogous with M_2SO_4, is probably a dihydroxyl acid, $CrO_2(OH)_2$. If this is so we should expect that each OH would be replaceable by Cl; the first compound thus produced, $CrO_2.Cl.OH$, ought to be a monobasic acid (analogous with $SO_2.Cl.OH$); this compound is not itself known, but several salts derived from it have been prepared, *e.g.* $CrO_2.Cl.OK$ (*v. infra*, under Chromates). *Fluo-*, *bromo-*, and *iodo-*, *chromates*, $CrO_2.X.OM$ (where X = F, &c., and M = alkali metal), are also known. Salts of the hypothetical *amido-chromic acid* ($CrO_2.NH_2.OM$) are known; and it is probable that *nitro-derivatives* of $K_2Cr_2O_7$ and $K_2Cr_3O_{10}$, respectively, have been obtained, viz. $Cr_2O_5.NO_2.OK$ and $Cr_3O_8.NO_2.OK$ (*v. Potassium dichromate*, under Dichromates). Cr_2O_3 reacts towards acids as a salt-forming or positive oxide; no acid corresponding to this oxide is known; the oxide is itself insoluble in H_2O. Salts $MO.Cr_2O_3$, where M = Zn, Mn, Fe, &c., have, however, been prepared, by fusing MO and Cr_2O_3 with B_2O_3, &c.; these may be regarded as derivatives of the hypothetical chromous acid $H_2Cr_2O_4$ (*v.* Chromites, p. 158). The sulphide Cr_2S_3, corresponding to Cr_2O_3, also reacts as a feebly salt-forming compound towards more positive sulphides (*v.* CHROMIUM, THIOACID OF, p. 168).

CHROMIC ACID H_2CrO_4. Said to be obtained as small red crystals by adding a little H_2O to excess of pure CrO_3, keeping the solution for some hours at 90°, decanting and cooling to 0° (Moissan, *A. Ch.* [6] 5, 568). But Miss Field has shown that the crystals thus obtained are CrO_3; the solution, however, probably contains H_2CrO_4 and $H_2Cr_2O_7$ (*C. J.* 61, 405 [1892]). The thermal values of the reaction between NaOHAq and H_2CrO_4Aq show that this acid is dibasic; salts of the form $MHCrO_4$ appear not to exist as solids; if enough alkali is added to saturate half the H_2CrO_4 in solution, and the liquid is evaporated, the salt $M_2Cr_2O_7$ is obtained - probably $2MHCrO_4$ is formed and decomposed to $M_2Cr_2O_7$ and H_2O. If H_2CrO_4Aq is added to solution of M_2CrO_4, $M_2Cr_2O_7$ is obtained on evaporation. The thermal data (*Th.* 1, 255) show (1) the dibasicity of the acid, and (2) the action of excess of acid on the normal salts: the corresponding data for H_2SO_4Aq are given; addition of H_2SO_4Aq to K_2SO_4Aq produces $KHSO_4Aq$:—

n	[nNaOHAq, CrO^3Aq]	m	[$m$$CrO^3$Aq, 2NaOHAq]
1	13,134	$\frac{1}{2}$	12,582
2	24,720	1	24,720
4	25,164	2	26,268

n	[nNaOHAq, SO^3Aq]	m	[$m$$SO^3$Aq, 2NaOHAq]
1	14,754	$\frac{1}{2}$	15,689
2	31,378	1	31,378
4	31,368	2	29,508

Chromates. (*Di-, tri-, tetra-, chromates.*) M_2CrO_4 or $M^{II}CrO_4$; also basic and double salts. Chromates are mostly yellow or red; the salts of the alkali metals, and of Ca, Mg, and Sr, are e. sol. water, the others are generally insol. or sl. sol. They are formed by the action of bases on H_2CrO_4Aq; by fusing Cr_2O_3 with alkali in presence of air; or by double decomposition from the alkali salts. Neutral M_2CrO_4Aq (M = alkali metal) goes red on addition of a mineral acid from formation of $M_2Cr_2O_7Aq$, on adding alkali the yellow colour returns. Chromates are easily reduced to Cr_2O_3 or salts of this oxide; *e.g.* boiling HClAq produces $CrCl_3Aq$, and chloride of the metal, H_2SO_4Aq produces Cr_23SO_4Aq. Chromates of the less positive metals give Cr_2O_3 when strongly heated; $M_2Cr_2O_7$ (M = alkali metal) give Cr_2O_3, O, and M_2CrO_4. Insoluble chromates yield alkali chromates by fusion with KOH or NaOH. Heated with NaCl and conc. H_2SO_4, chromates give CrO_2Cl_2. Solutions of chromates have a metallic taste, and are poisonous.

Aluminium chromate. — The basic salt $Al_23CrO_4.2Al_2O_3.21H_2O(=Al_2O_2.CrO_4.7H_2O)$ is a flocculent yellow pp. obtained by adding K_2CrO_4Aq to alum solution, or by evaporating $Al_2O_3.xH_2O$ in CrO_3Aq (Fairrie, *C. J.* 4, 300; Mans, *P.* **11**, 81; Elliot a. Storer, *P. Am. A.* 5, 192).

Ammonium chromate.—$(NH_4)_2CrO_4$. Citron-yellow needles; e. sol. water; gives off NH_3 in air; on heating leaves Cr_2O_3. Obtained by slowly adding CrO_2Cl_2 to excess of NH_3Aq, and evaporating below 60°; also by $BaCrO_4 + (NH_4)_2SO_4Aq$, and by $CrO_3Aq + NH_3Aq$ (Darly, *A.* 65, 2041) (*v.* **Di-, Tri-, and Hexa-chromates**).

Barium chromate $BaCrO_4$. Yellow, crystalline powder; obtained by $K_2CrO_4Aq + BaCl_2Aq$; S.G. 3·9; also by fusing 1 pt. K_2CrO_4 with 1 pt. Na_2CrO_4 and 2 pts. $BaCl_2$, and cooling slowly; S.G. 4·6 (Bourgeois, *Bl.* [2] 31, 243). Insol. H_2O; sol. HClAq, or HNO_3Aq, and reppd. by NH_3Aq. Decomposed by alkali carbonates and sulphates (Rose, *P.* 95, 426) (*v.* **Dichromates**).

Beryllium chromate.—Basic salt $BeCrO_4.13BeO.23H_2O$; yellow pp., insol. H_2O (Creuzburg, *D. P. J.* 163, 449).

Bismuth chromates (Löwe, *J. pr.* 67, 288 a. 463; Pearson, *P. M.* [4] 11, 204; Pattison Muir, *C. J.* [2] 15, 12; [2] 16, 24 a. 645). Normal chromate, Bi_23CrO_4, has not been prepared. The following basic salts are known: — $2(Bi_23CrO_4).7Bi_2O_3$, by ppg. $Bi3NO_3$ in smallest excess of HNO_3Aq by K_2CrO_4Aq; $2(Bi_23CrO_4).Bi_2O_3$, by ppg. a more acid solution of $Bi3NO_3$ in HNO_3Aq by K_2CrO_4Aq; $(Bi_23CrO_4).2Bi_2O_3$, by boiling the preceding salt with dilute HNO_3Aq or with alkali; $3(Bi_23CrO_4).Bi_2O_3$, by prolonged heating $2(Bi_23CrO_4).Bi_2O_3$ with dilute HNO_3Aq; $7(Bi_23CrO_4).2Bi_2O_3$, by treating $(Bi_23CrO_4).2Bi_2O_3$ first with conc., then with dilute, HNO_3Aq. These salts are all yellow to red, heavy, crystalline powders; insol. water, and slowly decomposed by hot acids (*v.* also **Dichromates**).

Cadmium chromate.—Basic salt $CdCrO_4.CdO.H_2O$; by reaction of $CdSO_4Aq$ with large excess of K_2CrO_4Aq (Freese, *B.* 2, 476; Sarzeau a. Malaguti, *A. Ch.* [3] 9, 431).

Calcium chromate $CaCrO_4.2H_2O$; by dissolving $CaCO_3$ in CrO_3Aq and evaporating. Yellow prisms; S. (14°) ·41; insoluble in alcohol; loses its H_2O at 200° (Siewert, ***Z. f. d. g. Naturwiss.*** 19, 11) (*v.* **Dichromates**).

Cerium chromate $Ce(CrO_4)_2$; yellow powder, by dissolving $Ce(CrO_4)_2$ in CrO_3Aq and evaporating (Beringer, *A.* 42. 143).

Chromium chromate $(Cr_23CrO_4).2Cr_2O_3$. This name and composition is sometimes assigned to CrO_2 (*v.* **Chromium dioxide** under **Chromium, oxides of**, p. 164.)

Cobalt chromates.—Basic cobaltous salt $CoCrO_4.CoO.$[illegible]H_2O (Freese, *B.* 2, 476); $CoCrO_4.2CoO.4H_2O$ (Sarzeau a. Malaguti, *A. Ch.* [3] 9, 431). Clear red-brown pp. by $Co2NO_3Aq + K_2CrO_4Aq$. Cobaltic chromate Co_23CrO_4 is known in combination with NH_3 and NH_4Cl; the salts $(Co_23CrO_4).10NH_3$, $(Co_23CrO_4).12NH_3.5H_2O$, and $(Co_23CrO_4).2NH_3.2NH_4Cl$, are described by Braun (*A.* 125, 153 a. 197), Gibbs a. Genth (*A.* 104, 150 a. 295), and Gibbs (*B.* 4, 790) (*v.* also **Chromium, ammonio-salts of**).

Copper chromates.—Basic salts: $CuCrO_4.2CuO.2H_2O$, yellowish-brown pp., by $K_2CrO_4Aq + CuSO_4Aq$, and by $CuSO_4Aq + K_2Cr_2O_7Aq$ and adding enough KOH to produce K_2CrO_4Aq (Freese, *P.* 140, 87; Rosenfeld, *B.* 13, 1469). Loses its H_2O at 260° and takes it up again in moist air. Two salts, $2(CuCrO_4).5CuO.5H_2O$, and $CuCrO_4.6CuO.5H_2O$, are described by Rosenfeld (*l.c.*); obtained by adding $CuSO_4Aq$ to $K_2Cr_2O_7Aq$ with excess of KOHAq. The salt $CuCrO_4.2CuO.2H_2O$ dissolves in NH_3Aq at 0°; dark-green crystals of $2(CuCrO_4)CuO.10NH_3.2H_2O$ separate (Sarzeau a. Malaguti, *A. Ch.* [3] 9, 431; Viefhaus, *J. pr.* 88, 431; Slater, *J. pr.* 60, 247) (*v.* also *Potassium chromate*).

Iron chromate.—Basic ferric salt $(Fe_23CrO_4).2Fe_2O_3$; brown pp. by K_2CrO_4Aq acting on iron-alum solution; decomposed by H_2O to Fe_2O_3 and CrO_3Aq. An acid salt, $Fe_23CrO_4.CrO_3$, is said to be formed by digesting CrO_3Aq with $Fe_2O_6H_6$, and evaporating (Kletzinsky, *D. P. J.* 207, 83; Elliot a. Storer, *P. Am. A.* 5, 192).

Lead chromate $PbCrO_4$. Occurs native as *red-lead ore*, in yellow, translucent, monoclinic prisms, S.G. 5·2 to 6·1. Obtained as yellow pp. by K_2CrO_4Aq or $K_2Cr_2O_7Aq$ acting on neutral solution of a Pb salt; also in crystals by strongly heating K_2CrO_4 with $PbCl_2$, S.G. of crystals 6·12 (Manross, *A.* 82, 348; Drevermann, *A.* 87, 120). S.H. ·09 (Kopp, *A. Suppl.* 3, 1). Insol. in H_2O, sol. in HNO_3Aq or KOHAq; melts without change, but at higher temperature gives O, Cr_2O_3, and a basic salt ($PbCrO_4.PbO$). Acts as an oxidiser, hence used in organic analysis (*v.* Vohl, *A.* 106, 127).

Basic salt $PbCrO_4.PbO$; red crystals, obtained by throwing $PbCrO_4$ in small quantities into molten KNO_3, cooling somewhat, pouring off still liquid part, and quickly washing residue with H_2O; also by digesting $PbCrO_4$ with cold KOHAq, or with hot K_2CrO_4Aq. Insol. in H_2O; sol. in KOHAq; acids withdraw PbO (Wöhler a. Liebig, *P.* 21, 580). Another basic salt, $2(PbCrO_4).PbO$, occurs native as *Melanochroïte*, and is said to be formed by diffusing K_2CrO_4Aq and $Pb2NO_3Aq$ (Drevermann, *A.* 87, 120). Lead chromates are used as pigments.

Lithium chromate $Li_2CrO_4.H_2O$; red trimetric crystals, easily sol. in H_2O. A double salt, $Li.NH_4.CrO_4.2H_2O$, is obtained by saturating $Li_2Cr_2O_7Aq$ with NH_3Aq (Rammelsberg, *B. B.* 1865. 629) (*v.* **Dichromates**).

Magnesium chromate $MgCrO_4.7H_2O$. Citron-yellow soluble crystals; isomorphous with $MgSO_4.7H_2O$; S.G. 1·66–1·75; by dissolving MgO in CrO_3Aq and evaporating (Kopp, *A.* 42, 100; Grailich, *W. B.* 27, 174).

The double salt, $MgCrO_4.NH_4CrO_4{}6H_2O$ crystallises from a solution of its constituents; yellow monoclinic crystals, isomorphous with corresponding double sulphates (Grailich, *l.c.*). *v.* also *Potassium chromate*.

Manganese chromate.—Basic manganous salt; $MnCrO_4.MnO.2H_2O$, brown pp. by reaction of boiling $MnSO_4Aq$ and K_2CrO_4Aq (Fairrie, *C. J.* 4, 300; Freese, *P.* 140, 87; Warington, *P. M.* [3] 21, 380; Reinsch, *P.* 55, 97).

Mercury chromates.—Mercurous chromate Hg_2CrO_4; red crystalline powder; by reaction of

IgNO$_3$Aq and K_2CrO_4Aq or $K_2Cr_2O_7$Aq (H. Rose, P. 53, 124; Freese, *Z.* [2] 6, 30). Decomposed by heat to Hg, O, and Cr_2O_3 (Darly, *A.* 65, 204; Freese, *P.* 140, 87). By action of alkalis a black basic salt, $Hg_2CrO_4.2Hg_2O$, is obtained (Richter, *B.* 15, 1489).

Mercuric chromate $HgCrO_4$; dark, garnet-red, trimetric prisms; obtained by evaporating equal parts of yellow HgO and CrO_3 in H_2O. Decomposed by H_2O to CrO_3Aq and $HgCrO_4.2HgO$. Decomposed by acids (Geuther, *A.* 106, 247; Millon, *A. Ch.* [3] 18, 365).

The basic salt $HgCrO_4.2HgO$ is a brick-red powder, obtained by boiling HgO with K_2CrO_4Aq, or by reaction of Hg2NO$_3$Aq and $K_2Cr_2O_7$Aq (Millon, *A. Ch.* [3] 18, 365; Freese, *Z.* [2] 6, 30).

A double salt $2(HgCrO_4).HgS$ is obtained by digesting freshly ppd. HgS with solution of freshly ppd. HgO in CrO_3Aq, and drying at 30°; easily explodes when rubbed (Palm, *J.* 1862. 221) (*v.* also *Ammonium dichromate*).

Nickel chromate.—Basic salt $NiCrO_4.2NiO.6H_2O$; brown pp. by reaction between $NiSO_4$Aq and K_2CrO_4Aq. Loses its H_2O above 300° (Freese, *P.* 140, 87). Other basic nickel chromates are described by Schmidt (*A.* 156, 19). A double compound, $NiCrO_4.6NH_3$, is obtained in yellow dichroïc crystals by addition of alcohol to a solution of the basic salt in presence of NH_3Aq; the crystals lose NH_3 in the air (Schmidt, *l.c.*).

Potassium chromate K_2CrO_4. S.G. $\overset{\circ}{-}$ 2·71. S.H. ·189 (Kopp, *A. Suppl.* 3, 1). C.E. (0°–100°) ·01134 (Joule a. Playfair, *C. J.* 1, 121; Schiff, *A.* 107, 64). S. (0°) 58·9; (20°) 62·94; (60°) 71·02; (100°) 79·1: boiling-point of saturated solution = 104·2° (Michel a. Kraft, *A. Ch.* [3] 41, 471; Schiff, *A.* 108, 326; v. Hauer, *J. pr.* 103, 114). Freezing-point of saturated solution = –12·5° (Rüdorff, *P.* 122, 337). S.G. $\overset{19\cdot5^\circ}{-}$ 38·44 p.c. solution = 1·3787; 17·09 p.c. solution = 1·1476; 8·54 p.c. solution = 1·0703; 4·27 p.c. solution = 1·0349 (Michel a. Kraft, *A. Ch.* [3] 41, 417; Alluard, *C. R.* 59, 500).

Preparation.—1. By heating 5 parts $K_2Cr_2O_7$ with 4 parts KNO_3 or K_2CO_3 until the whole fuses quietly, dissolving in water, and crystallising.—2. By neutralising $K_2Cr_2O_7$Aq with K_2CO_3, evaporating and crystallising.—3. By fusing Cr_2O_3 with K_2CO_3 and KNO_3, dissolving in water and crystallising.—4. By fusing chrome-ironstone with K_2CO_3 and CaO_2H_2, lixiviating with H_2O, boiling down, and crystallising.

Properties.—Pale lemon-yellow, double six-sided trimetric pyramids; isomorphous with K_2SO_4. Melts without change. Insol. alcohol. Solution in H_2O is alkaline, with metallic taste, and is poisonous; on evaporation, this solution gives crystals of $K_2Cr_2O_7$, and mother liquor gives crystals of K_2CrO_4.

Reactions.—1. *Acids*, even CO_2Aq, produce $K_2Cr_2O_7$ (Schweitzer, *N. R. P.* 3, 212; Margueritte, *J. pr.* 64, 502; Mohr, *Fr.* 1872. 278).—2. Reduced by H_2S or K_2SAq, with formation of $Cr_2O_3.xH_2O$, and by SO_2Aq with production of Cr_23SO_4Aq.—3. With HCl gas, KCl, H_2O, and $K_2Cr_2O_7$ are formed, and then the $K_2Cr_2O_7$ is reduced to $CrCl_3$ and CrO_2 (Thomas, *C. J.* 33, 371).

Combinations.—1. With various *chromates* to form double salts. $K_2CrO_4.(NH_4)_2CrO_4$ crystallises from conc. $K_2Cr_2O_7$Aq saturated with NH_3 (Berthier, *A. Ch.* [3] 7, 77; Johnson, *J. pr.* 62, 261). $K_2CrO_4.CaCrO_4.2H_2O$ crystallises from $K_2Cr_2O_7$Aq neutralised by CaO_2H_2Aq.

$K_2CrO_4.5CaCrO_4$ obtained by slowly evaporating a mixture of $CaCl_2$Aq and K_2CrO_4Aq (Bahr, *J. pr.* 60, 60; Duncan, *J. pr.* 50, 54; Rammelsberg, *P.* 98, 507). $K_2CrO_4.2CuCrO_4.CuO.2H_2O$, obtained by reaction between cold $CuSO_4$Aq and K_2CrO_4Aq, or by adding KOHAq to mixture of $K_2Cr_2O_7$Aq and $CuSO_4$Aq (Freese, *P.* 140, 87). $K_2CrO_4.Fe_23CrO_4.4H_2O$, by reaction between conc. Fe_2Cl_6Aq and K_2CrO_4Aq, dissolving pp. in HClAq, cooling, and washing rapidly with cold H_2O (Hengson, *B.* 12, 1300 a. 1656). $K_2CrO_4.MgCrO_4.2H_2O$; by evaporating conc. $K_2Cr_2O_7$Aq after neutralising by MgO or $MgCO_3$ (Hauer, *J. pr.* 80, 222; Schweitzer, *A.* 64, 276). $K_2CrO_4.2ZnCrO_4.2ZnO.3H_2O$; by prolonged action of cold $ZnSO_4$Aq on excess of K_2CrO_4Aq (Freese, *B.* 2, 476; Prüssen a. Philippona, *A.* 149, 92).—2. With *mercuric chloride* and *cyanide*, to form $K_2CrO_4.2HgCl_2$, and $2K_2CrO_4.3Hg(CN)_2$, respectively (Darly, *A.* 65, 204; Rammelsberg, *A.* 28, 217; 84, 281) (*v.* also **Di-, Tri-, and Tetra-chromates**; also **Bromo-, Chloro-, Fluo-, Iodo-, Chromates**).

Rubidium chromate Rb_2CrO_4. Yellow trimetric crystals, isomorphous with K_2CrO_4 and K_2SO_4 (Piccard, *J. pr.* 86, 449; Grandeau, *A. Ch.* [3] 67, 155).

Silver chromate Ag_2CrO_4. Dark-red crystals; by reaction between K_2CrO_4Aq and $AgNO_3$Aq, or by digesting moist Ag_2O with K_2CrO_4Aq. Insol. H_2O; sol. acids, NH_3Aq, and alkali chromates; KOHAq withdraws all CrO_3. Under H_2O is slowly reduced by Zn, Cd, Sn, &c. (Freese, *P.* 140, 87; Fischer, *P.* 8, 488). Combines with NH_3 to form $Ag_2CrO_4.4NH_3$; produced in yellow crystals, isomorphous with corresponding sulphate and selenate, by dissolving Ag_2CrO_4 in hot NH_3Aq and crystallising (Mitscherlich, *P.* 12, 141; Wöhler a. Rantenberg, *A.* 114, 119).

Sodium chromate $Na_2CrO_4.10H_2O$; yellow, deliquescent crystals, isomorphous with $Na_2SO_4.10H_2O$. Prepared similarly to K_2CrO_4 (Johnson, *J. pr.* 62, 261; Kopp, *A.* 42, 100) (*v.* also **Dichromates**).

Thallium chromate Tl_2CrO_4. Yellow pp. obtained by reaction between K_2CrO_4Aq and neutral solution of a thallous salt (Carstanjen, *J. pr.* 102, 65 a. 129; Hebberling, *A.* 134, 11; Strecker, *A.* 135, 207; Crookes, *C. N.* 8, 255) (*v.* also **Di-, and Tri-chromates**).

Thorium chromate $Th_2CrO_4.8H_2O$; crystallises by evaporating a solution of Th_2O_3 in CrO_3Aq (Chydenius, *P.* 119, 43).

Zinc chromates.—Various basic salts are obtained by the reactions between $ZnSO_4$Aq and K_2CrO_4Aq: the most marked seems to be $ZnCrO_4.ZnO.2H_2O$ (Sarzeau a. Malaguti, *A. Ch.* [3] 9, 431; Thomson, *P. M.* 3, 81; Prüssen a. Philippona, *A.* 149, 92). By dissolving this salt in a little NH_3Aq, and adding alcohol, $ZnCrO_4.4NH_3.3H_2O$ is obtained (Sarzeau a. Malaguti, *l.c.*; Bieler, *A.* 151, 223) (*v.* also *Potassium chromate*).

Chromates of In (Meyer, *A.* 150, 137); Mo; Sr; Sn (Leykauf, *J. pr.* 19, 127); U; and Yb (Popp, *A.* 131, 179) seem to exist, but very little is known concerning them, nor have their compositions been satisfactorily determined.

Fluo-, Bromo-, Chloro-, and Iodo-chromates; also Amido-chromates (*v. supra* beginning of this art., p. 154). Salts derived from the hypothetical acids, *fluochromic* $CrO_2.F.OH$, *bromochromic* $CrO_2.Br.OH$, &c., and *amidochromic* $CrO_2.NH_2.OH$. These acids are not themselves known.

Potassium fluochromate $CrO_2.F.OK$. Ruby red, semitransparent, crystals; efflorescent in air; melts when heated; acts on glass. Prepared by heating powdered $K_2Cr_2O_7$ in a Pt dish with excess of conc. HFAq (Streng, *A.* 129, 225; Heintze, *J. pr.* [2] 4, 225; Varenne, *C. R.* 89, 358; 91, 389).

Potassium bromochromate $CrO_2.Br.OK$. Dark-brown crystals; gives up Br in an exsiccator; decomposed by H_2O. Obtained by saturating conc. $K_2Cr_2O_7Aq$ with fuming HBrAq, and crystallising from HBrAq (Heintze, *J. pr.* [2] 4, 225).

Potassium chlorochromate $CrO_2.Cl.OK$. Obtained by heating for a short time 3 parts $K_2Cr_2O_7$ with 4 parts conc. HClAq and a little H_2O, and cooling; or by adding CrO_2Cl_2 to KClAq, or to K_2CrO_4Aq slightly acidified with acetic acid:

$$K_2Cr_2O_7 + 2HClAq = 2CrO_2.Cl.OK + H_2OAq;$$
$$CrO_2Cl_2 + KClAq + H_2O = CrO_2.Cl.OK + 2HClAq;$$
$$CrO_2Cl_2 + K_2CrO_4Aq = 2CrO_2.Cl.OK + Aq$$

(Péligot, *A. Ch.* 52, 267; Geuther, *A.* 106, 240). This salt is also produced, along with Cr_2O_3, when violet $CrCl_3$ reacts with molten $K_2Cr_2O_7$ (Geuther, *A.* 118, 68). Large red prisms; S.G. $\frac{4^\circ}{}$ 2·497; C.E. (0°–100°) ·0159 (Playfair a. Joule, *C. J.* 1, 121). May be crystallised unchanged from H_2O containing a little acid; crystals of $K_2Cr_2O_7$ separate from an aqueous solution. Cl is evolved at 100°. Decomposed by conc. H_2SO_4 with formation of CrO_2Cl_2 and $Cr_3O_6Cl_2$ (*q. v.*); with NO_2 gives NO_2Cl (Heintze, *J. pr.* [2] 4, 211). By reaction with conc. KCNAq, CNCl is formed. By the action of dry NH_3, salt having the composition $K_2Cr_3O_8$ (?$CrO_2.OK.CrO_2.OK.CrO_2$) is formed, along with KCl and NH_4Cl; if the chlorochromate is suspended in $(C_2H_5)_2O$ and NH_3 is passed in, crystals of potassium amidochromate $CrO_2.NH_2.OK$ (*q. v.*) are formed (Heintze, *J. pr.* [2] 4, 211).

Chlorochromates of Na—$CrO_2.Cl.ONa.2H_2O$; of NH_4—$CrO_2.Cl.ONH_4$; of Ca, Sr, Ba, Mg, Ni, Co, and Zn—$(CrO_2.Cl.O)_2M.xH_2O$; have also been prepared, by adding CrO_2Cl_2 to fairly conc. solution of the metallic carbonates in CrO_3Aq. When M = Mg, Ni, Co, or Zn, the salts crystallise with $9H_2O$; when M = Ca, with $5H_2O$; when M = Sr, with $4H_2O$; and when M = Ba, with H_2O (Péligot, *A. Ch.* 52, 267; Prætorius, *A.* 201, 1).

Potassium iodochromate $CrO_2.I.OK$. Obtained, as garnet-red, easily decomposed, crystals, by gently heating conc. colourless HIAq with finely powdered $K_2Cr_2O_7$ (Guyot, *C. R.* 73, 46).

Potassium amidochromate $CrO_2.NH_2.OK$. Finely powdered $CrO_2.Cl.OK$ is slowly added to water and ether (free from alcohol), the liquid is simultaneously saturated with NH_3; after standing 24 hours, the ether is poured off, the residue is gently warmed to get rid of adhering ether, and is then treated with water; the liquid is evaporated at a low temperature, and allowed to crystallise. The salt is recrystallised from H_2O, and the crystals are dried at 100°. Garnet-red. unchanged by cold H_2O, or cold NaOHAq; decomposed by H_2O, or NaOHAq, at 100 , giving $CrO_2.OK.ONH_4$, and $CrO_2.OK.ONa$, respectively; decomposed by nitrous acid to $K_2Cr_2O_7$, N, and H_2O. $CrO_2.NH_2.OK$ is changed by dry NH_3 to a dark-brown powder, from which H_2O removes NH_4Cl and leaves a crystalline salt, $Cr_3O_6(OK)_2$: the corresponding NH_4 salt is obtained by acting on CrO_2Cl_2 dissolved in $CHCl_3$ with NH_3, and reacting with H_2O (Heintze, *J. pr.* [2] 4, 214).

Dichromates $M_2Cr_2O_7$ and MCr_2O_7. Most of these salts are soluble in water; many of them are decomposed by water. The greater number are salts of monovalent metals. They are obtained by the action of acids on M_2CrO_4.

Ammonium dichromate $(NH_4)_2Cr_2O_7$. Orange coloured, monoclinic, crystals; S.G. 2·367; decomposed by heat to Cr_2O_3, H_2O, and N. Prepared by neutralising CrO_3Aq with NH_3Aq, adding an equal quantity of CrO_3Aq, and evaporating (Richmond a. Abel, *C. J.* 3, 199; Siewert, *Z. f. d. g. Naturwiss.* 19, 11; Schabus, *P.* 116, 420; Weiss, *Sitz. W.* 37, 373; Rammelsberg, *P.* 118, 158; Schiff, *A.* 107, 64). Two double compounds with $HgCl_2$, viz. $(NH_4)_2Cr_2O_7.HgCl_2.H_2O$, and $3(NH_4)_2Cr_2O_7.HgCl_2$, exist (Darly, *A.* 65, 204; Zepharovich, *Sitz. W.* 39, 17; Clarke a. Stern, *Am.* 3, 351).

Barium dichromate $BaCr_2O_7.2H_2O$; yellow needles, obtained by dissolving $BaCrO_4$ in conc. CrO_3Aq, evaporating, crystallising, and drying at 100°. Decomposed by H_2O to $BaCrO_4$ and CrO_3Aq (Bahr, *J. pr.* 60, 30; Zettnow, *P.* 144, 167; Preis a. Rayman, *B.* 13, 340).

Bismuth dichromate.—The salt $2(Bi_23CrO_4).Bi_2O_3$, obtained by ppg. $Bi3NO_3$ in HNO_3Aq by K_2CrO_4Aq, described as a basic bismuth chromate (p. 155), may perhaps be better regarded as basic bismuth dichromate $(BiO)_2Cr_2O_7$.

Calcium dichromate $CaCr_2O_7.3H_2O$; deliquescent, red, crystals; obtained by dissolving $CaCrO_4$ in CrO_3Aq and evaporating (Bahr, *J. pr.* 60, 60).

Copper dichromate $CuCr_2O_7.2H_2O$; brown-black, deliquescent, crystals; e. sol. in H_2O or alcohol; decomposed by hot H_2O with separation of $CuCrO_4.2CuO$; obtained by dissolving CuO_2H_2 in conc. CrO_3Aq, and evaporating (Droege, *A.* 101, 39).

Lead dichromate $PbCr_2O_7$. Brick red, crystalline, powder; by action of CrO_3Aq on $PbCrO_4$ (Preis a. Rayman, *B.* 13, 340).

Lithium dichromate $Li_2Cr_2O_7$; black-brown, deliquescent, crystals (Rammelsberg, *B. B.* 1865. 629).

Potassium dichromate $K_2Cr_2O_7$. S.G. $\frac{4^\circ}{}$ 2·692 (Joule a. Playfair, *C. J.* 1, 121; Schiff, *A.* 107, 64). M.P. about 400° (Tilden a. Shenstone, *T.* 1884. 34). S.H. ·186 (Kopp, *A. Suppl.* 3, 1 a. 289). C.E. (0°–100°) ·0122 (Joule a. Playfair, *C. J.* 1, 121). S. (0°) 4·9; (10°) 8·4; (40°) 29·2; (80°) 73; (100°) 102; (117°) 128·3; (129°) 153·8, (148°) 200·6; (180°) 262·7. S.G. of solution 6·08 parts in 100 water = 1·0405 at 19·5°, of 13·1 parts in 100 water = 1·0847; saturated solution boils at 104°; insol. alcohol (Kremers, *P.* 92, 497; 95, 110; 96, 39; Alluard, *C. R.* 59, 600; Michel a. Kraft, *A. Ch.* [3] 41, 471; Tilden a. Shenstone, *T.* 175, 28).

Preparation.—Chrome-ironstone is heated, powdered, and mixed with K_2CO_3 and CaO; the mixture is heated to 150° until quite dry, then to bright redness, in presence of air, with frequent stirring. The fused mass is allowed to cool, and is then treated with a small quantity of boiling water; if the solution contains $CaCrO_4$ it is decomposed by adding K_2CO_3 and filtering from $CaCO_3$. Sufficient acid to change the K_2CrO_4 to $K_2Cr_2O_7$ is added, the liquid is evaporated and allowed to crystallise. The crystals are purified by recrystallisation from water.

Properties.—Large, red, triclinic, crystals; unchanged in air. Solution in water is acid to litmus, has a metallic taste, and is poisonous. Is rapidly changed by light in presence of organic matter; hence used in photography (Schwann, *D. P. J.* 199, 130). Decomposed at white heat to K_2CrO_4, O, and Cr_2O_3.

Reactions.—Reduced by heating with C, S, or NH_4Cl; or with solid $H_2C_2O_4$ (Bothamley, *C. J.* 51, 159; Werner, *C. J.* 53, 602); $K_2Cr_2O_7Aq$ is reduced by SO_2Aq to Cr_23SO_4Aq, and by H_2S to Cr_2O_3 and S; NO is absorbed and after a time CrO_2 is ppd. (Vogel, *J. pr.* 77, 482). Heated with conc. H_2SO_4, K_2SO_4, Cr_23SO_4, H_2O, and O are produced; addition of 2 formula-weights H_2SO_4 to a boiling solution of one formula-weight $K_2Cr_2O_7$ produces pp. of orange-red $HKSO_4.K_2Cr_2O_7$, which is decomposed by H_2O (Schwarz, *D. P. J.* 186, 31). Solution of $K_2Cr_2O_7$ in conc. HClAq gives $CrO_2.Cl.OK$ (*q. v.*) on cooling. From a hot solution of the salt in 12 parts HNO_3Aq, carmine-red crystals of $Cr_2O_5.NO_2.OK$ ($?OK.CrO_2.O.CrO_2.NO_2$) separate on cooling; by re-crystallising this salt from HNO_3Aq, the salt $Cr_3O_8.NO_2.OK$ ($?OK.CrO_2.O.CrO_2.O.CrO_2.NO_2$) is obtained (Darmstädter, *B.* 4, 117). A double compound $K_2Cr_2O_7.HgCl_2$ is obtained by evaporating a mixture of its constituents (Darly, *A.* 65, 204; Hahn, *Ar. Ph.* [2] 99, 147).

Rubidium dichromate $Rb_2Cr_2O_7$; and *Sodium dichromate*, $M_2Cr_2O_7$; closely resemble $K_2Cr_2O_7$ (Piccard, *J. pr.* 86, 449; Grandeau, *A. Ch.* [3] 67, 155).

Silver dichromate $Ag_2Cr_2O_7$. By ppg. $K_2Cr_2O_7Aq$ by $AgNO_3$, or digesting moist Ag_2O with $K_2Cr_2O_7Aq$; somewhat soluble in H_2O, crystallising in red, triclinic, crystals; decomposed by boiling water; when strongly heated gives Cr_2O_3 and Ag (Freese, *P.* 140, 87; Warington, *P. M.* 11, 489; Teschemacher, *P. M.* 1, 345; Nason, *A.* 104, 126).

Thallium dichromate $Tl_2Cr_2O_7$. Red, crystalline, powder; insol. in H_2O; decomposed by conc. acid to $Tl_2Cr_3O_{10}$ (*q. v. infra*). Obtained by reaction of thallous salts with $K_2Cr_2O_7Aq$.

Tri-, Tetra-, and Hexa-Chromates: $M^I{}_2Cr_3O_{10}$, $M^I{}_2Cr_4O_{13}$, and $M^I{}_2Cr_6O_{19}$. Very few of these salts are known. $(NH_4)_2Cr_3O_{10}$, $K_2Cr_3O_{10}$, and $Tl_2Cr_3O_{10}$ are obtained by crystallising solutions of the dichromates in HNO_3Aq (Siewert, *Z. f. d. g. Naturwiss.* 19, 11; Bothe, *J. pr.* 46, 184; Hauer, *Sitz. W.* 39, 439; Willm, *A. Ch.* [4] 5; 5). $K_2Cr_4O_{13}$ is obtained by long-continued digestion of $K_2Cr_3O_{10}$ in conc. HNO_3Aq (Siewert, *l.c.*). $(NH_4)_2Cr_6O_{19}.10H_2O$ was obtained by Rammelsberg (*P.* 94, 507) from a solution of $(NH_4)_2Cr_2O_7$.

Chromites. *Compounds of Cr_2O_3 with more positive metallic oxides.* A compound $2CaO.Cr_2O_3$ is obtained, according to Chancel (*C. R.* 43, 97), by the reaction between NH_3Aq and chrome-alum solution mixed with $CaCl_2$. By mixing solutions in KOHAq of Cr_2O_3 and PbO or ZnO, pps. are obtained of the composition $MO.Cr_2O_3$ (Pelouze, *A. Ch.* [3] 33, 5). Compounds of the form $MO.Cr_2O_3$, where M = Mn, or Zn, are also produced by fusing together the component oxides with B_2O_3 at a white heat; the compounds crystallise out on cooling; $ZnO.Cr_2O_3$ forms dark green octahedra, S.G. 5·309; $MnO.Cr_2O_3$, hard iron-grey octahedra, S.G. 4·87 (Ebelmen, *A. Ch.* [3] 33, 34). These compounds may be regarded as chromites, MCr_2O_4, *i.e.* salts of the hypothetical chromous acid $H_2Cr_2O_4$. Certain metallic oxides which are insoluble in KOHAq become soluble therein when mixed with $Cr_2O_3.xH_2O$; *e.g.* a mixture of $Cr_2O_3.xH_2O$ with 40 p.c. Fe_2O_3, 12·5 p.c. MnO, 20 p.c. CoO, or 25 p.c. NiO, is completely soluble in KOHAq; on the other hand Cr_2O_3 is completely ppd. by KOHAq in presence of 80 p.c. Fe_2O_3, 60 p.c. MnO, or 50 p.c. CoO or NiO (Church, *Ph. C.* 1853. 391).

Chromium, alloys of. An alloy of Cr with Al is described by Wöhler (*A.* 106, 118) as very fusible, tin-white, crystals; becoming brittle after fusion; S.G. 4·9. Fremy (*C. R.* 44, 632) obtained an alloy with Fe by reducing chrome-ironstone with C, or by the action of Fe on Cr_2O_3 at a very high temperature; long needles, harder than steel. By the action of Na amalgam on $CrCl_3Aq$ an amalgam of Cr with Hg is produced (Vincent, *P. M.* [4] 24, 328; Schönbein, *P.* 112, 445).

Chromium, ammonio- salts of; or Chrom-ammonium salts. Freshly ppd. $Cr_2O_3.xH_2O$ dissolves in conc. NH_4ClAq containing NH_3Aq; on standing in air a reddish-violet powder is deposited; when this is dissolved in cold HClAq and excess of conc. HClAq is added, a rose-red crystalline powder is produced having the composition $Cr_2Cl_6.8NH_3.2H_2O$. By treating this salt with cold conc. H_2SO_4, a new compound $Cr_2Cl_2(SO_4)_2.8NH_3.2H_2O$ is produced; by the action of BaI_2Aq on this, the salt $Cr_2Cl_2I_4.8NH_3.2H_2O$ is formed; and from this, $Cr_2Cl_2Br_4.8NH_3.2H_2O$ may be obtained by the action of conc. HBrAq. Various other derivatives are known of the general form $Cr_2M_2.X_4.8NH_3.xH_2O$, in which M = Cl, Br, or I, and X = negative radicle, Cl, Br, I, NO_3, $\frac{CrO_4}{2}$, &c. The reactions of this series of compounds forbid us to regard them as ordinary double compounds of Cr_2M_6 with xNH_3; they are usually looked on as compounds of the hypothetical groups, *chlorochrom-*, *bromochrom-*, *iodochrom-tetrammonium*, with negative radicles Cl_4, $(NO_3)_4$, &c. On this supposition the formula $N_4H_8(NH_4)_4.(Cr_2M_2).X_4$ would represent the compounds in question; the names *chloro-* (bromo-, iodo-,) *chromtetrammonium chloride*, *bromide*, &c., are used. The less hypothetical formula $M_2.Cr_2.8NH_3.X_4$ is also frequently employed to represent the chloro(&c.)chromtetrammonium compounds.

Six other series of chromammonio-compounds are known. They may all be represented by the general form $Cr_2.xNH_3.X_6$, where $x = 10$ or 12, and X = negative radicle; in some of these part of the X_6 is easily replaced by other radicles and part is not; in others the whole of the X_6 is easily replaced. If M represent the radicle which is replaced with difficulty, and X the radicle which is easily replaced, we get the developed general formula for the seven series of compounds $M_x.Cr_2.8(10 \text{ or } 12)NH_3.X_z$; where $x = 1$, or 2, and $z = 4$, 5, or 6. The second to seventh series may also be regarded as derived from the first (*i.e.* from the chloro(&c.)chromtetrammonium salts, by replacing H in $N_4H_8(NH_4)_4.(Cr_2M_2).X_4$ by the radicle NH_4. The following formulæ represent the seven series of compounds:—

(1) $M_2.Cr_2.8NH_3.X_4$ or $N_4H_8(NH_4)_4.(Cr_2M_2).X_4$
Chromtetrammonium salts.

(2) $M_2.Cr_2.10NH_3.X_4$ or $N_4H_6(NH_4)_6(Cr_2M_2).X_4$
Purpureochrom salts.

(3) $Cr_2.10NH_3.X_6$ or $N_4H_6(NH_4)_6.Cr_2.X_6$
Roseochrom salts.

(4) $M_2.Cr_2.10NH_3.X_4$ or $N_4H_6(NH_4)_6(Cr_2M_2)X_4$
Xanthochrom salts; ($M_2 = 2NO_2$).

(5) $Cr_2.12NH_3.X_6$ or $N_4H_4(NH_4)_8.Cr_2.X_6$
Luteochrom salts.

(6) & (7) $M.Cr_2.10NH_3.X_5$ or $N_4H_6(NH_4)_6(Cr_2M).X_5$
Rhodochrom and *Erythrochrom salts*; (M = OH).

The purpureo- and roseo- salts are isomeric, using the term in a rather wider sense than is given to it in organic chemistry as the molecular weights of none of these salts are known; $AgNO_3Aq$ pps. $\frac{4}{6}$ of the Cl from purpureochromium chloride in the cold, but all the Cl from roseochromium chloride; HNO_3Aq, HBrAq, &c., also removes $\frac{4}{6}$ of the Cl from the former salts; boiling HIAq, however, produces $I_2.Cr_2.10NH_3.I_4$ (*iodopurpureochromium iodide*); and by acting on this with dilute HClAq, $I_2.Cr_2.10NH_3.Cl_4$ (*iodopurpureochromium chloride*) is obtained. Purpureo- compounds, in which M_2 and X_4 are the same radicle (*e.g.* $Br_2.Cr_2.10NH_3.Br_4$, or $Cl_2.Cr_2.10NH_3.Cl_4$) easily change to roseo- compounds by standing in the air, or by heating. Xanthochromium chloride is obtained by the action of $NaNO_2Aq$ and dilute HNO_3Aq on $Cl_2.Cr_2.10NH_3.Cl_4$, or on $Cr_2.10NH_3.Br_6$. The three series, purpureo- luteo- and rhodo- salts, are obtained by more or less slowly oxidising Cr_2Cl_4 in NH_4ClAq in presence of NH_3Aq; the purpureo- and rhodo- salts are obtained by oxidising in presence of air, the luteo- salts in absence of air (*v. infra*). The roseo- and erythro- salts are obtained from the purpureo- and rhodo- respectively (*v. infra*). The rhodo- and erythro- salts are isomeric; the former change to the latter by standing in air (*v. infra*).

In the nomenclature of the chromtetrammonium and purpureochromium salts it is necessary to use prefixes, chloro-, bromo-, &c., to express the nature of the radicles M_2; thus chloropurpureochromium chloride, and bromopurpureochromium nitrate, are $Cl_2.Cr_2.10NH_3.Cl_4$, and $Br_2.Cr_2.10NH_3.(NO_3)_4$, respectively. In the other series prefixes are unnecessary.

It will suffice here to describe the chief compounds in each series. The principal references are Fremy, *A. Ch.* [4] 9, 431; Clève, *J. pr.* 76, 47; *Am. S.* [2] 49, 251; Jörgensen, *J. pr.* [2] 20, 105; 25, 83; 25. 321; 30, 1; Christensen, *J. pr.* [2] 23, 26; 24, 74; 25, 398.

I. Chromtetrammonium Series

$M_2.Cr_2.8NH_3.X_4.xH_2O$. *Chlorochromtetrammonium chloride* $Cl_2.Cr_2.8NH_3.Cl_4.2H_2O$. Deep-red, very lustrous, almost opaque, trimetric crystals. Obtained by digesting freshly ppd. chromium hydroxide in a closed flask with conc. NH_4Cl in NH_3Aq, until the hydroxide dissolves: the deep-red liquid is allowed to stand in the air, the dark-violet powder which separates is dissolved in cold HClAq, excess of conc. HClAq is added, the rose-red crystalline powder which separates out is washed with conc. HClAq, then with strong alcohol, and is crystallised from warm H_2O containing a little HCl. This compound begins to decompose at 120°; when strongly heated NH_3, NH_4Cl, and H_2O, are given off, and Cr_2O_3 remains; heated in air-free H, or in CO_2, Cr_2OCl_4 remains. The salt is soluble in water, but on boiling $Cr_2O_3.xH_2O$ and NH_3 are produced. Treated with H_2O and moist Ag_2O, a liquid is obtained probably containing $Cl_2.Cr_2.8NH_3.(OH)_4$; it soon decomposes with evolution of NH_3.

The *sulphate* $Cl_2.Cr_2.8NH_3.(SO_4)_2.2H_2O$ is obtained by treating the chloride with cold conc. H_2SO_4, and then with H_2O; from this the *iodide* ($X_4 = I_4$) is produced by the action of BaI_2Aq, and by the action of fuming HBrAq on this, the *bromide* ($X_4 = Br_4$) is produced.

If freshly ppd. $Cr_2O_3.xH_2O$ is treated with NH_4Br in NH_3Aq, *bromochromtetrammonium bromide*, $Br_2.Cr_2.8NH_3.Br_4.2H_2O$ is produced; an aqueous solution of this salt dropped into conc. HClAq gives the *bromo-chloride* ($M_2 = Br_2$, $X_4 = Cl_4$).

II. Purpureochromium series

$M_2.Cr_2.10NH_3.X_4$. *Chloropurpureochromium chloride.* $Cl_2.Cr_2.10NH_3.Cl_4$. Prepared by reducing $K_2Cr_2O_7$ by alcohol and very conc. HClAq, so that 12g. $K_2Cr_2O_7$ give 50 c.c. $CrCl_3$ solution, pouring the liquid (from KCl) through a separating funnel into a cylinder fitted with a reversed U-tube and an exit tube, and containing sticks of Zn, and adding a little HClAq; when the liquid is the colour of $CuSO_4Aq$ (which indicates reduction to $CrCl_2$), forcing it through the U-tube into a solution of 600 g. NH_4Cl in 1,000 c.c. NH_3Aq, S.G. ·9; and repeating this operation until 50 g. $K_2Cr_2O_7$ have been reduced, and the $CrCl_3$ solution further reduced to $CrCl_2$ and driven into the ammoniacal NH_4ClAq. The blue liquid is then oxidised, by long-continued passage of air, until it becomes deep carmine-red; 2½ litres of conc. HClAq are added, the liquid is boiled for a few minutes, when the chloride separates out as a carmine-red crystalline powder. This liquid is allowed to cool, and poured off, the residue is washed free from NH_4Cl by conc. HClAq + an equal volume of H_2O, collected on a filter and again washed with the same HClAq, dissolved in H_2O slightly acidified with H_2SO_4, and re-ppd. by conc. HClAq; the pp. is boiled with a little conc. HClAq, washed with the same strength of HClAq as before, then with 90 p.c. alcohol, and dried at about 18°–20°.

Chloropurpureo-chromium chloride crystallises in small carmine-red octahedra: S.G. $\underline{14{\cdot}5^\circ}$

1·687; S. (16°) ·65; insol. conc. HClAq; on boiling an aqueous solution roseochromium chloride is obtained; decomposed by heat, giving Cr_2O_3.

Bromo-bromide ($M_2 = Br_2$, $X_4 = Br_4$) is prepared similarly to the chloro-chloride, using NH_4Br in place of NH_4Cl, &c. By treatment with excess of HClAq it yields *bromo-chloride* ($M_2 = Br_2$, $X_4 = Cl_4$). By treating chloro-chloride with boiling conc. HIAq *iodo-iodide* ($M_2 = I_2$, $X_4 = I_4$) is formed. By the action of dilute HNO_3Aq, H_2SO_4Aq, &c., on chloro-chloride, *chloro-nitrate*, *chloro-sulphate*, &c., are obtained ($M_2 = Cl_2$, $X_4 = 4NO_3$, $2SO_4$, &c.); the action of K_2CrO_4Aq produces *chloro-chromate* ($M_2 = Cl_2$, $X_4 = 2CrO_4$). Besides these the following compounds have been prepared:—

M_2	X_4	M_2	X_4	M_2	X_4
Cl_2	$2SiF_6$	Br_2	$2PtBr_6$	I_2	Cl_4
		Br_2	$4NO_3$	I_2	$4NO_3$
		Br_2	$2CrO_4$	I_2	$2PtCl_6$

III. ROSEOCHROMIUM SERIES $Cr_2.10NH_3.X_6$. *Roseochromium chloride*, $Cr_2.10NH_3.Cl_6$. Obtained by rubbing 5 g. dry chloropurpureochloride with the moist Ag_2O from 20 g. $AgNO_3$ for a few minutes in a mortar, filtering, neutralising the alkaline liquid with HClAq, filtering from AgCl, evaporating in a rapid air-stream, pressing pp. between paper, washing once with a little H_2O, and drying in air out of direct sunlight. Orange-yellow crystals; v. sol. H_2O; insol. alcohol; very unstable, giving off NH_3; changed, as are all roseo- salts, by heating with conc. HClAq, to purpureo- salt. $AgNO_3Aq$ pps. all the Cl in the cold.

The other roseo- salts are formed by neutralising the solution obtained by action of moist Ag_2O on purpureo-chloride by various acids; the solution in question probably contains roseo-hydroxide [$X_6 = (OH)_6$]. The chief roseo- salts are $X_6 = Br_6$, I_6, $3SO_4$, $6NO_3$, $Br_2(PtBr_6)_2$, $(SO_4)_2PtCl_6$, $Br_2(CrO_4)_2$.

IV. XANTHOCHROMIUM SERIES $(NO_2)_2.Cr_2.10NH_3.X_4$. *Xanthochromium chloride*, $(NO_2)_2.Cr_2.10NH_3.Cl_4$. To 20 g. chloropurpureochloride 300 c.c. warm water and about 20 drops dilute HNO_3Aq are added, the liquid is slowly heated to boiling, then cooled, and filtered; the insoluble purpureo-chloride is again treated in the same way; 40–50 g. *pure* $NaNO_2$ and 25 c.c. HClAq (12 p.c.) are added to the total liquid; the yellow crystalline salt which separates out is washed with water, then with alcohol, dissolved in water, and ppd. by fairly conc. NH_4ClAq. Xantho-chloride is a yellow crystalline powder; fairly sol. H_2O; insol. alcohol; easily decomposed by acids with production of HNO_2; treated with HClAq, chloropurpureo-chloride is formed; fairly stable towards alkalis; forms double salts with $2PtCl_4$ and $4HgCl_2$.

The other most important xantho- salts are: $X_4 = Br_4$, I_4, $2SO_4$, $2S_2O_3$, $4NO_3$, $2CO_3$, $2CrO_4$; the hydroxide, $X_4 = (OH)_4$, is known in aqueous solution, it is fairly stable, and has a strongly alkaline reaction.

V. LUTEOCHROMIUM SERIES $Cr_2.12NH_3.X_6$. *Luteochromium nitrate*, $Cr_2.12NH_3.(NO_3)_6$. 80 g. $K_2Cr_2O_7$ are reduced to $CrCl_2$ by the method described under chloropurpureochromium chloride; the solution is forced by H pressure into a flask containing 700 g. NH_4Cl in 750 c.c. NH_3Aq (S.G. ·91); the flask, which must be entirely filled with the liquid, is closed by a cork carrying an exit tube opening under water, and is surrounded by cold water; after about 24 hrs. evolution of H ceases; the liquid is poured off from ppd. luteo-chloride and NH_4Cl, and is ppd. by alcohol; the crude luteo-chloride is washed with alcohol, dried, dissolved in warm water, and the solution is filtered into HNO_3Aq (S.G. 1·39); the crystals of luteo-nitrate are washed with dilute HNO_3Aq (1 vol. conc. HNO_3Aq to 2 vols. H_2O), and then with alcohol. The pp. of mixed NH_4Cl and luteo-chloride formed in the process may be dissolved by repeated treatment with H_2O, and luteo-nitrate obtained by ppn. with HNO_3Aq. Luteo-nitrate crystallises in orange-yellow, lustrous plates; S. (abt. 15°) 2·5; insol. alcohol; nearly insol. dilute HNO_3Aq.

The luteo-chromium salts form many double compounds with acid radicles, and also with some negative metallic radicles; the more important salts are:—$X_6 = 2NO_3.2SO_4$, $2NO_3.2PtCl_6$, Cl_6, Br_6, I_6, $Cl_4.H_2PtCl_6$, $Cl_2.2PtCl_6$, $3PtCl_6$, $3PtBr_6$, $I_2.2SO_4$, $3SO_4$, $2SO_4.PtCl_6$, $3C_2O_4$, $2NaP_2O_7$, $Fe_2(CN)_{12}$, $Co_2(CN)_{12}$, $Cr_2(CN)_{12}$ (Jörgensen, *J. pr.* [2] 30, 1).

VI. RHODOCHROMIUM SERIES $OH.Cr_2.10NH_3.X_5$. *Rhodochromium bromide*, $OH.Cr_2.10NH_3.Br_5.H_2O$. $Cr_2O_3.xH_2O$, equal to 10 g. Cr_2O_3, is dissolved in 100 c.c. conc. HBrAq; the green solution is poured on to Zn in a cylinder arranged with a reversed U-tube, &c., as described under purpureochloride; 30 c.c. HBrAq (1 vol. conc. solution + 1 vol. H_2O) are added; when the liquid is blue (after about 10 min.) 30 c.c. of the same HBrAq are added, and the H pressure is caused to force the liquid into 150 g. NH_4Br in 750 c.c. conc. NH_3Aq; the blue solution is oxidised by a stream of air, after all particles of Zn have been removed; the liquid is quickly decanted from the blue pp. (basic rhodo-bromide), which is treated with excess of HBrAq (1 vol. conc. solution + 3 vols. H_2O), whereby red rhodo-bromide is formed; the salt is washed with dilute HBrAq and then with water, it is then dissolved in cold water and the liquid is poured into moderately dilute HBrAq; the crystals which separate are washed with dilute HBrAq and then with alcohol, and are dried in the air. Dried for some days over H_2SO_4 they lose their H_2O. Rhodo-bromide is a pale carmine-red crystalline powder; slowly loses its H_2O over conc. H_2SO_4; sl. sol. cold H_2O; on warming, the solution goes blue-violet; on boiling, NH_3 comes off, and $Cr_2O_3.xH_2O$ pps.; insol. dilute HBrAq and NH_4BrAq; boiled with very dilute HBrAq it is changed to roseochromium bromide; boiled with conc. HBrAq it gives brompurpureo-bromide; with $AgNO_3$ all the Br is ppd.; dilute NaOHAq or NH_3Aq removes $\frac{1}{5}$ Br, and a basic rhodo- salt remains; dilute acids form the respective rhodo-salts.

The chief rhodo- salts known are:—$X_5 = Cl_5$, I_5, $5NO_3$, $2\frac{1}{2}CO_3$, $2\frac{1}{2}SO_4$, $2\frac{1}{2}S_2O_6$, $Cl_3.2AuCl_4$, $Cl_3.PtCl_6$, $Cl.2PtCl_6$; and the basic salts:—$X_5 = OH.Br_4$, $OH.Cl_2I_2$, $OH.2S_2O_3$ (Jörgensen, *J. pr.* [2] 25, 321).

VII. ERYTHROCHROMIUM SERIES $OH.Cr_2.10NH_3.X_5$. *Erythrochromium nitrate*, $OH.Cr_2.10NH_3.5NO_3.H_2O$. Rhodo-chloride is prepared by filtering a solution of rhodo-bromide into HClAq (1 vol. conc. solution + 1 vol. H_2O); it is washed with alcohol, 5 g. rhodo-chloride are dissolved in 50 c.c. H_2O + 35 c.c. dilute NH_3Aq; when the blue solution has become red by standing in air 4–5 vols. of dilute HNO_3Aq are added; the pp. is repeatedly treated with dilute HNO_3Aq, dissolved in H_2O, reppd. by HNO_3Aq, washed with alcohol, and dried in the dark. Erythrochromium nitrate is a crimson powder composed of microscopic octahedra; it decomposes slowly even in the dark; when strongly heated N oxides are evolved and Cr_2O_3 remains; fairly sol. cold water; insol. alcohol; aqueous solution decomposes when boiled with separation of $Cr_2O_3.xH_2O$; aqueous solution boiled with a few drops of HNO_3Aq gives roseochromium nitrate; solid erythronitrate boiled with dilute HClAq gives chlorpurpureo-chloride.

Other salts are obtained by the action of acids on the bromide or chloride; the principal are:—$X_5 = Br_5$, Cl_5, $2\frac{1}{2}SO_4$; and the basic salts $X_5 = OH.Br_4$, $OH.4NO_3$, $OH.2S_2O_6$ (Jörgensen, *J. pr.* [2] 25, 398).

Chromium, arsenates of.—Existence uncertain (*v.* ARSENATES, under ARSENIC, ACIDS OF; vol. i. p. 308).

Chromium, bromides of.—Two are known; as neither has been gasified the formulæ $CrBr_2$ and $CrBr_3$ may or may not represent the composition of the gaseous molecules; judging from the analogy of $CrCl_3$ it is probable that the formulæ $CrBr_2$ and $CrBr_3$ are molecular. These compounds resemble the chlorides (*q. v.*) in their properties.

I. CHROMOUS BROMIDE $CrBr_2$ or Cr_2Br_4. Obtained as white crystals by heating $CrBr_3$ in H, by leading HBr over heated Cr, or by the action of N saturated with Br vapour on Cr at a red heat (Moissan, *A. Ch.* [5] 25, 401). Unchanged in dry air, but oxidises in presence of traces of moisture; dissolves in H_2O forming blue liquid, which dissolves large quantities of violet $CrCl_3$.

II. CHROMIC BROMIDE $CrBr_3$ or Cr_2Br_6. Small cylinders formed of Cr_2O_3, C, and starch paste, are dried and heated to redness in a covered crucible; they are then heated in a tube of hard glass in dry Br vapour; crystals of $CrBr_3$ sublime, and some remain mixed with, but easily separable from, Cr_2O_3. Dark, metal-like, lustrous, hexagonal crystals; olive-green by transmitted light, slightly dichroic in red light (Wöhler, *A.* 111, 382). Heated in air Cr_2O_3 is formed; KOHAq or NaOHAq decomposes $CrBr_3$ into Cr_2O_3 and KBrAq or NaBrAq. Insol. in H_2O, but dissolves in presence of a little $CrBr_2$. A green solution containing $CrBr_3$ is obtained by the action of HBrAq on $Cr_2O_6H_6$.

Chromium, chlorides of.—Two exist, $CrCl_2$ and $CrCl_3$. Chromic chloride has been gasified (at 1200°–1500°) and the observed V.D. corresponds with the formula $CrCl_3$; it is probable, but not certain, that the molecular formula of chromous chloride is $CrCl_2$.

$CrCl_3$, like several other compounds of Cr, exists in two forms; one sol., the other insol. in H_2O. $CrCl_2Aq$ is an energetic reducer. Solutions of CrO_2 and CrO_3 in cold conc. HClAq may contain $CrCl_4$ and $CrCl_6$ respectively; these solutions are brown, they evolve Cl when heated, and $CrCl_3$ remains.

I. CHROMOUS CHLORIDE $CrCl_2$ or Cr_2Cl_4. Mol. w. unknown.

Formation.—1. By the action of dry HCl on Cr at a red heat (Ufer, *A.* 112, 302; Moissan, *A. Ch.* [5] 25, 401).—2. By heating $CrCl_3$ with NH_4Cl to a very high temperature (Moissan, *l.c.*).

Preparation.—Violet, sublimed $CrCl_3$ is heated in a stream of perfectly dry H, free from every trace of O, to a very low red heat; the reduction takes place very slowly, but the temperature must not be raised, else some Cr will be formed (Moberg, *J. pr.* 29, 175; 43, 125; 44, 322; Péligot, *A. Ch.* [3] 12, 528). The H used should be passed through a solution of $SnCl_2$ in KOHAq, then through conc. H_2SO_4, then over red hot Cu, and lastly through boiled H_2SO_4 and over $CaCl_2$.

Properties.—White lustrous crystals; sol. in H_2O, with production of heat, forming a blue liquid, which rapidly absorbs O turning green. Péligot determined the quantity of O absorbed; it corresponded with formation of Cr_2Cl_4O. Loewel (*A. Ch.* [3] 40, 42), by the prolonged action of granulated Zn on a solution of $CrCl_3.6H_2O$ in 3–5 parts H_2O in a flask nearly filled with the Zn, obtained a colourless solution of $CrCl_2$ (containing Zn), which acted as a strong reducer; *e.g.* K_2CrO_4Aq was reduced to CrO_2, $HgCl_2Aq$ to HgCl, $CuSO_4Aq$ to Cu_2Cl_2 and Cu_2O, and solutions of Au and Sn salts to Au and Sn.

Reactions.—$CrCl_2Aq$ protected from air gives the following reactions:—1. With *potash* or *soda*, brownish-yellow CrO_2H_2, which quickly becomes CrO_3H_3 with evolution of H.—2. *Potassium sulphide* pps. black Cr_2S_3.—3. *Sodium acetate* forms a red liquid from which red lustrous crystals of $Cr(C_2H_3O_2)_2.H_2O$ separate after a time.

Combinations.—1. With *water*, to form $2CrCl_2.3H_2O$ (Moissan, *A. Ch.* [5] 25, 401).—2. With dry *hydrochloric acid*, to form an easily decomposed compound $6CrCl_2.4HCl.26H_2O$ (Recoura, *C. R.* 100, 1227).

II. CHROMIC CHLORIDE $CrCl_3$. Mol. w. 158·55. V.D. 77·45 (Scott, *Pr. E.* 14, 410).

Formation.—By heating Cr_2S_3 in dry Cl (Berzelius, *P.* 50, 79; Brunner, *D. P. J.* 159, 356).

Preparation.—An intimate mixture of Cr_2O_3 and lampblack is made into little pellets with starch paste; the pellets are dried and heated in a covered crucible, they are then placed in a Hessian crucible, through the bottom of which is fitted a porcelain tube about 6 inches long; the upper end of this tube, which passes a very little way into the crucible, is loosely covered with a very small crucible to prevent the pellets falling into the tube; into the mouth of the Hessian crucible is fitted a smaller crucible, inverted, and pierced by a hole. The crucibles are arranged in a furnace, so that the lower one may be heated very highly and the upper kept comparatively cool. The porcelain tube is connected with a supply of dry Cl. The pellets are now heated in a rapid stream of Cl; $CrCl_3$ sublimes into the upper crucible; the whole is allowed to cool in Cl, else Cr_2O_3 may be formed. The sublimate is washed with cold H_2O to remove Al_2Cl_6 formed from the crucible (Wöhler, *A.* 111, 230; Ufer, *A.* 112, 281).

Properties.—Lustrous, peach-blossom coloured plates. S.G. 3·03 (Schafarik, *J. pr.* 90, 12). Decomposed at high temperature without fusion with evolution of Cl (Carnelley a. Williams, *C. J.* 37, 126). Insol. in water, unacted on by acids, even by *aqua regia.* $CrCl_3$ may be obtained in soft violet-coloured plates, v. sol. in H_2O, by dissolving green CrO_3H_3 in HClAq, evaporating slowly until crystals of $CrCl_3.6H_2O$ separate, and heating these in HCl or Cl not above 250° (Moberg, *J. pr.* 44, 325; Péligot, *J. pr.* 37, 475). $CrCl_3$ thus prepared dissolves very easily in H_2O, forming a green solution; heated above 250° the salt sublimes to crystals of the peach-blossom coloured, insoluble variety. The latter crystals when powdered and boiled with water for some time go into solution with production of a green liquid (Jacquelin, *C. R.* 24, 679).

A violet solution of $CrCl_3$ is produced by decomposing violet Cr_23SO_4Aq by an equivalent quantity of $BaCl_2Aq$. When this solution is boiled it becomes green.

The green solutions evaporated at 100° give crystals of $CrCl_3.xH_2O$ (*v. Combinations*, No. 1); the same green hydrates of $CrCl_3$ are obtained by dissolving green CrO_3H_3 in HClAq, or the insoluble $CrCl_3$ in H_2O containing a trace of $CrCl_2$, or $PbCrO_4$ in conc. HClAq and reducing by alcohol, and evaporating at about 100°; evaporated at higher temperatures oxy-chlorides (*q. v.*) are obtained. These green solutions probably therefore contain $CrCl_3$. But only two-thirds of the total Cl is ppd. from them in the cold by $AgNO_3Aq$; on boiling for some time the rest of the Cl also forms AgCl. On the other hand, $AgNO_3Aq$ pps. all the Cl from the violet-coloured solution of $CrCl_3$ obtained by the action of $BaCl_2Aq$ on violet Cr_23SO_4Aq. Moreover, green-coloured double chlorides, $MCl.CrCl_3$, where M = alkali metal, are not obtained, whereas several violet double chlorides are known (*v. Combinations*, No. 2). Péligot (*J. pr.* 37, 475) supposed that a green solution of $CrCl_3$ contains CrOCl and HCl; Berzelius (*P.* 50, 79) supposed that on adding $AgNO_3$ a double compound of AgCl and $CrCl_3$ is formed and that this is decomposed only on boiling.

Reactions.—1. Finely powdered $CrCl_3$ boiled for some time with *water* slowly dissolves, forming a green solution (Jacquelin, *C. R.* 24, 679). If the water contains $\frac{1}{1000}$ to $\frac{1}{4000}$ of its weight of $CrCl_2$, or a little $SnCl_2$ or Cu_2Cl_2, the $CrCl_3$ quickly dissolves with production of much heat, forming a green liquid with the same reactions as that obtained by dissolving CrO_3H_3 in HClAq (Péligot, *J. pr.* 36, 150; Loewel, *J. pr.* 37, 150; Pelouze, *P.* 24, 233; Moberg, *A.* 109, 82; Barreswill, *A. Ch.* 12, 528) (*v. Combinations*, No. 1; also CHROMIUM, OXYCHLORIDES OF).—2. Boiled with *potash* or *soda* $CrCl_3$ is slowly decomposed with formation of Cr_2O_3.—3. Fused with *nitre and an alkali or alkaline carbonate* chromate and chloride of the alkali metal are formed.—4. Molten *potassium dichromate* forms $CrO_2.Cl.OK$ (Geuther, *A.* 118, 61).—5. Heated with *chromic anhydride* Cr_2O_3 and CrO_2Cl_2 are produced.—6. Heated in *air* Cr_2O_3 results.—7. Heated in dry *hydrogen* $CrCl_2$, and then Cr, is formed.—8. *Zinc* or *potassium* reduces $CrCl_3$ to Cr when heated with it.—9. Heated in *ammonia* CrN is formed.—10. Heated in *phosphoretted hydrogen* CrP results.—11. Heated in *sulphuretted hydrogen* or with *sulphur* the product is Cr_2S_3.

Combinations.—1. With *water*, to form various green, crystalline, easily soluble hydrates:—$2CrCl_3.9H_2O$, by evaporating CrO_3H_3 in HClAq in dry air at 100° (Moberg, *J. pr.* 29, 175); $CrCl_3.6H_2O$, by evaporating (1) violet $CrCl_3$ in H_2O containing a trace of $CrCl_2$ in dry air, or (2) solution obtained by action of conc. HClAq and alcohol on $PbCrO_4$ (Péligot, *J. pr.* 37, 475; Moberg, *J. pr.* 44, 326). Godefroy (*Bl.* [2] 43, 229) describes also $CrCl_3.10H_2O$, and $CrCl_3.4H_2O$, as green crystals. One or other of these hydrates is probably formed when violet $CrCl_3$ dissolves in H_2O containing a trace of $CrCl_2$; Loewel (*J. pr.* 37, 150) supposes that the $CrCl_3$ is reduced to $CrCl_2$ by the action of the $CrCl_2$ present, and that the $CrCl_3$ thus formed combines with H_2O and dissolves as $CrCl_3.xH_2O$, and that more $CrCl_3$ is reduced by the freshly formed $CrCl_2$, and so on (*v.* also Recoura, *C. R.* 102, 921). According to Recoura (*C. R.* 102, 513 a. 548) the hydrate $2CrCl_3.13H_2O$ exists in two varieties: (1) green crystals, produced by passing HCl into a saturated solution of green $CrCl_3$ (or by passing air into cooled $CrCl_2Aq$ containing much HCl, and then passing in HCl; *C. R.* 102, 921); (2) greyish blue crystals, produced by heating a solution of 1 pt. of the green crystals in 1 pt. water, and then saturating with HCl. The green crystals dissolve in water (S. = 130) without production of heat; the greyish blue crystals dissolve very readily in water with production of much heat $[2CrCl^3.13H^2O, Aq] = 24,000$. — 2. With *alkali chlorides* to form double salts $MCl.CrCl_3$, the properties of which are little known; prepared by treating $M_2Cr_2O_7$ (M = K, Na, or NH_4) with HClAq and alcohol, and evaporating at 100° until the residue is violet. On adding H_2O solution occurs, the liquid is yellow-red, but soon becomes green. Godefroy (*Bl.* [2] 42, 194) says that various double metallic chlorides containing $CrCl_3$ may be obtained by passing Cl into a mixture of metallic chromate and alcohol, and washing the products with HClAq; these double salts are decomposed by H_2O, but are unchanged in HClAq containing 32½ p.c. HCl.—3. With *phosphoric chloride* to form $2CrCl_3.2PCl_5$; obtained by heating the constituent chlorides in a sealed tube, and then to 140°–150° in an open vessel (Cronander, *B.* 6, 1466).—4. With *ammonia* to form several compounds (*v.* CHROMIUM, AMMONIO-SALTS OF).

Chromium, cyanides of, and their derivatives *v.* CYANIDES.

Chromium, fluorides of. Only one is known with fair certainty. CrF_3 is described by Deville (*C. R.* 43, 970) as forming lustrous, monometric, octahedra; obtained by dissolving dry CrO_3H_3, which has not been strongly heated, in HFAq, evaporating in a Pt dish, and heating the green mass to a very high temperature. The double salts $CrF_3.2MF.H_2O$, where M = Na, K, or NH_4, are described by Wagner (*B.* 19, 896).

Unverdorben (*P.* 7, 311) obtained a red gas by heating fluorspar and $PbCrO_4$ with conc. H_2SO_4. Dumas (*A. Ch.* [2] 31, 435) prepared the compound as a deep red liquid, by warming 4 pts. dry $PbCrO_4$, 3 pts. dry pure CaF_2, and 5–7 pts. very conc. H_2SO_4, in a retort of Pt or Pb, and leading the gas through a well-cooled tube of Pt and Pb into a Pt receiver. The liquid is volatile; the vapour acts on the mucous membranes and produces violent coughing; it is at once decomposed in ordinary air, or by H_2O, to HF and CrO_3; it acts rapidly on glass, forming SiF_4

The formula CrF_6 was given from estimations of the quantities of CrO_3 and HF produced by leading the gas into water. Rose (*P.* 27, 565) found more F than agreed with CrF_6. Oliveri (*G.* 16, 218) recently examined this supposed fluoride; according to him it is an oxyfluoride CrO_2F_2 analogous to CrO_2Cl_2.

Chromium, hydrated oxides of, *v.* Chromium, hydroxides of.

Chromium, hydroxides of. Several compounds of Cr with H and O are known. They react rather as hydrated oxides than as hydroxides (*v.* art. Hydroxides). Chromous hydroxide, or hydrated chromous oxide, $CrO_2H_2(CrO.H_2O)$ is very easily oxidised; it behaves towards acids as a salt-forming compound. At least three hydrates of Cr_2O_3 are known:—

$Cr_2O_3.7H_2O(Cr_2O_6H_6.4H_2O)$,
$Cr_2O_3.4H_2O(Cr_2O_6H_6.H_2O)$,

and $Cr_2O_3.H_2O(Cr_2O_2.O_2H_2)$; these compounds are all salt-forming in their reactions with acids, but at the same time they exhibit feebly acidic functions. The hydrate $CrO_3.H_2O(CrO_2.O_2H_2)$ is a strongly marked acid.

The hydrates of Cr are more or less easily separated into oxide and H_2O by the action of heat; the oxide Cr_2O_3 does not directly combine with water; CrO_3 readily combines with H_2O, but the solution is separated into CrO_3 and H_2O by boiling; the action of CrO towards H_2O is not known as the oxide has not been prepared.

I. Chromous hydroxide. CrO_2H_2 or $CrO.H_2O$. It is doubtful whether this compound has been obtained quite free from $Cr_2O_3.xH_2O$. A solution of $CrCl_2$ in air-free water, and protected from air, gives a yellowish-brown pp. with KOH dissolved in air-free H_2O (Moberg, *J. pr.* 43, 114 a. 125). The hydroxide quickly absorbs O and becomes dark brown; it rapidly decomposes H_2O, and combines with part of the O evolved. CrO_2H_2 is slowly dissolved by acids with separation of Cr and formation of chromous salts CrX_2, *e.g.* $CrSO_4.7H_2O$, $Cr(C_2H_3O_2)_2.H_2O$, &c.; these salts are unstable, and readily oxidise to chromic salts CrX_3 (Moberg, *J. pr.* 41, 330; Péligot, *A.* 52, 247) (*v.* Chromium, salts of, p. 167).

II. Chromic hydroxides. *Preparation.*—A clear blue pp. of $Cr_2O_3.xH_2O$ is obtained by the action of NH_3Aq on $CrCl_3Aq$ at the ordinary temperature. The $CrCl_3Aq$ must be perfectly free from any fixed alkali; it is prepared by dissolving Cr in HClAq, or $CrCl_3$ in H_2O containing a trace of $CrCl_2$, or by reducing CrO_3 by HClAq. When the pp. is thoroughly washed and dried over sulphuric acid the compound $Cr_2O_3.7H_2O(Cr_2O_6H_6.4H_2O)$ is obtained; when dried *in vacuo* $Cr_2O_3.4H_2O(Cr_2O_6H_6.H_2O)$ remains; and when dried at 200°-220° in H, the compound $Cr_2O_3.H_2O(Cr_2O_2.(OH)_2)$ is produced (Siewert, *Z. f. d. ges. Naturwiss.* 18, 244).

For accounts of the earlier experiments on composition of the various $Cr_2O_3.xH_2O$ *v.* Lefort, *J. pr.* 51, 261; Hertwig, *A.* 45, 298; Schaffner, *A.* 51, 168; Fremy, *C. R.* 47, 883; Ordway, *Am. S.* [2] 26, 197; Mitscherlich, *Lehrb. d. Chem.* [4th ed.] 2, 751; Vincent, *P. M.* [4] 13, 191).

The pp. obtained by the action of KOHAq or NaOHAq on $CrCl_3Aq$, or on solutions of other chromic salts, contains alkali which cannot be removed by hot water.

Graham (*T.* 1861. 183), by long-continued dialysis of solution of freshly ppd. $Cr_2O_3.xH_2O$ in $CrCl_3Aq$, obtained a liquid containing 1·5 pts. HCl to 98·5 Cr_2O_3(=HCl:31·2Cr_2O_3:xH_2O); this solution, which may be taken as nearly pure $Cr_2O_3.xH_2O$ dissolved in water, was unchanged on dilution or boiling, but was coagulated by addition of traces of salts, with separation of $Cr_2O_3.xH_2O$.

A green hydrate—approximately pure $Cr_2O_3.2H_2O$—known as Guignet's green, is obtained by heating 10 pts. $K_2Cr_2O_7$ and 18 pts. crystallised boric acid to low redness, and treating with H_2O. It is scarcely soluble in boiling HClAq (*v.* Scheurer-Kestner, *Bl.* 1865. 23; Salvétat, *C. R.* 48, 295).

Properties and Reactions.—Any of the hydrates $Cr_2O_3.xH_2O$ heated to 200° in air takes up O, forming a black powder, which reacts with HClAq evolving Cl, and from which H_2O dissolves out CrO_3 (Siewert, *l.c.*; Krüger, *A.* 52, 249). The three hydrates where $x=7$, 4, or 1, are hygroscopic; $Cr_2O_3.H_2O$ is insol. in boiling dilute HClAq, the two others dissolve in acids forming chromic salts, CrX_3 (*v.* Chromium, salts of). The hydrates are sol. in KOHAq, but on standing or boiling they are reppd., and the pps. contain alkali; they are sl. sol. in NH_3Aq, but are reppd. on boiling.

The hydrates $Cr_2O_3.xH_2O$ react towards acids as salt-forming hydroxides; but they also exhibit slightly acidic functions. Thus, the pps. obtained by adding KOHAq to solutions of chromic salts cannot be washed free from alkali even by hot water. Also, NH_3Aq added to solution of a chromic salt mixed with a salt of Ca or Zn, &c., forms a pp. containing Cr_2O_3 and CaO or ZnO. &c. (Pelouze, *A. Ch.* [3] 33, 5). Solution of PbO or ZnO in KOHAq, mixed with solution of $Cr_2O_3.xH_2O$ in KOHAq, yields a pp. of $MO.Cr_2O_3$ (Chancel, *C. R.* 43, 927). By long digestion of $Cr_2O_3.xH_2O$ in conc. NH_3Aq a dark-blue compound of Cr_2O_3 with NH_3 is produced, insol. in water, but sol. in HClAq (*v.* Chromites; and Chromium, ammonio-salts of).

Chromium, iodides of. Very little is known regarding these compounds. None seems to have been definitely isolated (*v.* Walz, *C. N.* 26, 245). Moissan (*A. Ch.* [5] 25, 401) describes CrI_2, or Cr_2I_4, as a white salt, sol. in water with formation of blue liquid; obtained by the action of HI, or I vapour, on heated Cr.

Chromium, nitride of, CrN. Mol. w. unknown.

Preparation.—1. Finely powdered Cr is heated to whiteness in N; the metal is again powdered and heated in N, and this process is repeated several times. Unchanged Cr is dissolved out by conc. HClAq (Briegleb a. Geuther, *A.* 123, 228).—2. $CrCl_3$ dried at about 120° is strongly heated in dry NH_3, the process being repeated several times; the residual $CrCl_3$ is removed by long digestion in conc. HClAq in contact with Sn ($CrCl_2$ is formed and dissolved); the product is washed, and dried at 100°-120° (Ufer, *A.* 112, 281; *v.* also Liebig, *P.* 21, 359; Schrötter, *A.* 37, 148; Gmelin, *Gm.* 4, 139).

Properties and Reactions. — Heavy, black, amorphous powder. Heated to about 1500° in absence of air, it is decomposed to Cr and N (Ufer, *A.* 112, 281). It is unacted on by KOHAq.

by dilute acids, by conc. HClAq or HNO_3, by H, by steam, or by molten Na_2CO_3; *aqua regia* dissolves it slowly; cold conc. H_2SO_4 dissolves it with formation of $Cr_2(NH_4)_2(SO_4)_4.24H_2O$, and without evolution of N. *Heated in HCl gas*, $CrCl_3$ and NH_4Cl are formed. Slowly sol. in solutions of alkaline hypochlorites, with formation of alkaline chromates and N; decomposed by molten KNO_3, or $KClO_3$, with formation of K_2CrO_4 and N (Ufer, *l.c.*); decomposes NH_3 to N and H at red heat; unacted on by Cl in the cold, but when heated slight explosions occur, and $CrCl_3$ and N are produced.

Chromium, oxides of. Three oxides of Cr are known, Cr_2O_3, CrO_2, and CrO_3; Cr_3O_4, Cr_5O_9, and perhaps an oxide higher than CrO_3, probably exist. Cr_2O_3 acts as a salt forming oxide towards acids, and also shows feebly acidic properties; CrO_3 is distinctly an anhydride, it reacts with water to form the acid H_2CrO_4; with acids it forms chromic salts, CrX_3, and O; no salts corresponding to CrO_2 have been prepared, this oxide is said to evolve Cl by the action of HClAq. Chromous oxide, CrO, is not known, but approximately pure $CrO.H_2O$ (*v.* Chromium, hydroxides of) has been prepared. Cr_2O_3 is said to combine directly with O to form CrO_2; it is readily oxidised in presence of alkali to chromate M_2CrO_4, from which CrO_3 is obtained. Cr_3O_4 and Cr_5O_9, if they exist, may be regarded as $CrO.Cr_2O_3$ and $2Cr_2O_3.CrO_3$, respectively; CrO_2 is sometimes regarded as $Cr_2O_3.CrO_3$ (*v.* Chromium, acids of).

I. Chromic **oxide** Cr_2O_3 (*green oxide of chromium*). Mol. w. unknown as compound has not been gasified. S.G. 4·91 to 5·01 (Playfair a. Joule, *C. S. Mem.* 3, 57; Schröder, *P.* 106, 226). Schiff (*A.* 106, 114) gives S.G. 6·2 for crystallised Cr_2O_3. Crystallises in hexagonal forms; *a:c* = 1:1·3682. S.H. (21°–52°) ·177 (Kopp, *T.* 155, 71).

Occurrence.—As *chrome-ochre*; in combination with FeO in *chrome-ironstone*.

Formation.—1. By heating chromic hydroxide (*q. v.*).—2. By heating finely divided Cr in O. 3. By heating CrO_3.—4. By heating $(NH_4)_2Cr_2O_7$ or Hg_2CrO_4.—5. By heating $CrCl_3$ in air.

Preparation.—1. A mixture of 5 pts. finely powdered, dry, $K_2Cr_2O_7$, and 1 pt. S, is heated to redness in a crucible, and the product is washed with H_2O until all K_2SO_4 and K_2S are dissolved out (Lassaigne, *A. Ch.* [3] 14, 299; Dietrich, *W. J.* 1866. 273).—2. Equal parts of dry, powdered, $K_2Cr_2O_7$, and NH_4Cl, are mixed with a little Na_2CO_3, strongly heated so long as any gas (N) comes off, and the residue is washed free from KCl (Wöhler, *P.* 10, 46; Bottger, *A.* 47, 339).—3. *Crystalline* Cr_2O_3 may be prepared by passing vapour of CrO_2Cl_2 through a glass tube heated to low redness (Wöhler, *P.* 33, 341); or by heating to bright redness, in a Hessian crucible, a mixture of equal parts of dry, powdered, $K_2Cr_2O_7$ and NaCl, covered with a layer of NaCl, and washing the residue free from KCl and NaCl (Schiff, *A.* 106, 114; 108, 30). The crystalline oxide is also obtained by strongly heating the amorphous oxide in O (Sidot, *C. R.* 69, 201); or by fusing the amorphous oxide with $CaCO_3$ and B_2O_3 (Ebelmen, *A. Ch.* [3] 22, 211). Blake (*Am. S.* [2] 10, 352) found crystalline Cr_2O_3 in a furnace used for making K_2CrO_4 from chrome-ironstone. (For other methods of preparing amorphous Cr_2O_3 *v.* Barian, *A.* 40, 203; Berthier, *A. Ch.* [2] 17, 56; Böttger, *J. pr.* 103, 314. For other methods of preparing crystalline Cr_2O_3 *v.* Gentele, *J. pr.* 54, 187; Fremy, *A.* 49, 274; Müller, *P.* 127, 404; Otto, *A.* 142, 102.)

Properties and Reactions.—Amorphous Cr_2O_3 is a green powder, more or less dark, according to the method of preparation. Crystalline Cr_2O_3 forms very dark green, lustrous, hexagonal crystals; as hard as corundum; isomorphous with Fe_2O_3 and Al_2O_3. Cr_2O_3 which has been strongly heated, or crystalline Cr_2O_3, is insol. acids; fused with KNO_3, or $KHSO_4$, K_2CrO_4 is formed and dissolves in H_2O. Amorphous Cr_2O_3, if not strongly heated, dissolves in most acids to form chromic salts CrX_3. Cr_2O_3 is not reduced by H, and by C only when intimately mixed and strongly heated. Heated in Cl, CrO_2Cl_2 is formed; if the oxide is perfectly dry, a little $CrCl_3$ is produced (Moissan, *Bl.* [2] 34, 70); heated to about 110° in air, CrO_2 is produced (Moissan, *l.c.*); heated in H_2S, Cr_2S_3 results (Moissan, *l.c.*).

Combinations.—1. With *water*, indirectly, to form $Cr_2O_3.xH_2O$; *v.* Chromium, hydroxides of.—2. With several *metallic oxides* to form compounds $MO.Cr_2O_3$; *v.* Chromites; under Chromium, acids of, p. 158.

II. Chromium dioxide CrO_2. (*Chromium tetroxide. Brown oxide of chromium. Chromate of chromium.*) Mol. w. unknown. This oxide is a product (1) of the oxidation of Cr_2O_3, (2) of the reduction of CrO_3.

Formation.—1. By heating Cr_2O_3 in air, or O, to about 400° (Moissan, *A. Ch.* [5] 21, 243).—2. By heating $Cr_2O_3.xH_2O$ in air to about 250° (Kruger, *P.* 61, 219).—3. By the action of conc. Cr_23SO_4Aq, or $CrCl_3Aq$, on K_2CrO_4Aq (? $5K_2CrO_4Aq + Cr_23SO_4Aq$ $= 3K_2SO_4Aq + 2K_2Cr_2O_7Aq + 3CrO_2$) (Maus, *P.* 9, 127; Bensch, *P.* 55, 98).—4. By the action of $Na_2S_2O_3Aq$ on $K_2Cr_2O_7Aq$

$$(?\ 2K_2Cr_2O_7Aq + Na_2S_2O_3Aq$$
$$= K_2CrO_4Aq + K_2SO_4Aq + Na_2SO_4Aq + 3CrO_2)$$

(Popp, *A.* 156, 90). (For other methods *v.* Kopp, *C. N.* 11, 16; Vogel, *J. pr.* 77, 482; Siewert, *Z. f. d. ges. Naturwiss.* 18, 285; Schiff, *A.* 120, 207; Traube, *A.* 66, 106; Rammelsberg, *A.* 60, 203; Braun, *J. pr.* 90, 356; Oppenheim, *Bl.* [3] 1, 165).

Preparation.—NO is passed into warm dilute $K_2Cr_2O_7Aq$; CrO_2 is slowly ppd.: the solution must not become concentrated (? $2K_2Cr_2O_7Aq + 2NO$ $= 2KNO_3Aq + K_2CrO_4Aq + 3CrO_2$). The pp. is washed with H_2O, then with alcohol, and dried at 250° for a long time until the weight is constant (Schweizer, *J. pr.* 39, 269; Hintz, *A.* 169, 367).

Properties and Reactions.—Dark grey, almost black, powder; very hygroscopic. Loses O at 300°; heated in Cl to 250° a little $Cr_2O_6Cl_2$ is formed; heated with HClAq, or with mixture of HClAq and H_2SO_4Aq, evolves Cl (Moissan, *A. Ch.* [5] 21, 243); heated with KOHAq, out of contact with air, forms K_2CrO_4Aq and Cr_2O_3 (Moissan, *l.c.*); not acted on by PCl_5 (Hintz, *A.* 169, 367).

III. Chromium trioxide CrO_3. (*Chromic anhydride. Red oxide of chromium.*) Mol. w. unknown. S.G. 2·67–2·82 (Playfair a. Joule, *C. S. Mem.* 3, 57; Schafarik, *Sitz. W.* 47 [2nd part], 256). Crystallises in trimetric prisms; *a*:*b*:*c* = ·7246:1: ·6285. [About 190°] (Zettnow, *P.* 143, 468). S. (26°) 165 (Zettnow, *l.c.*).

Occurrence.—In combination with PbO, CuO, &c., in a few minerals.

Formation.—Chromates, M_2CrO_4, are produced by heating Cr_2O_3 with alkaline oxidisers, *e.g.* KOH, KNO_3, $KClO_3$; or by the action of oxidisers—*e.g.* Cl, $K_2Mn_2O_8Aq$—on $Cr_2O_3.xH_2O$ in KOHAq. CrO_3 is obtained from chromates by the action of strong acids.

Preparation.—300 grams commercial $K_2Cr_2O_7$ are warmed with 500 c.c. H_2O and 420 c.c. conc. H_2SO_4 until dissolved; after 10–12 hours the mother liquor is poured off from the crystals of $KHSO_4$; the solution is kept at 80°–90°, 150 c.c. conc. H_2SO_4 are added, and then H_2O drop by drop till the pp. of CrO_3 has just dissolved; the liquid is evaporated until crystallisation begins. After 10–12 hours the liquid is separated from crystals of CrO_3 by pouring through a funnel in which is placed a little filter of thin Pt pierced with small holes. The mother liquor yields a second and third crop of CrO_3 crystals, by evaporation. The crystals of CrO_3 are spread out on a porous plate, after 24 hours they are removed, 50 c.c. pure HNO_3Aq (S.G. 1·46) are added, and the whole is placed on another porous plate; if after 12 hours the CrO_3 still gives reactions for H_2SO_4 and K, 25 c.c. HNO_3Aq are added and exposure on a porous plate is repeated. The HNO_3 is now removed by warming the crystals in a basin, at first very slightly, then to a rather higher temperature (60°–80), until the crystals appear perfectly dry and fumes of HNO_3 are no longer evolved. About 84 p.c. of pure CrO_3 is obtained (Zettnow, *P.* 143, 468; modification of methods of Bolley, *A.* 56, 113, and Bunsen, *A.* 148, 289). CrO_3 may also be prepared from $PbCrO_4$ by the action of conc. H_2SO_4 (Schrotter, *P.* 59, 616); or by the action of HNO_3Aq (Duvillier, *C. R.* 75, 711); also from $BaCrO_4$ (Duvillier, *l.c.*); also by the action of moisture on a fluoride of Cr (? oxyfluoride; *v.* CHROMIUM FLUORIDE, p. 163) obtained by decomposing $PbCrO_4$ and CaF_2 by conc. H_2SO_4 (Unverdorben, *N. J. P.* 9, 26; Berzelius, *Lehrbuch* [5th ed.], 2, 319).

Properties.—Carmine-red, very lustrous, trimetric prisms (Nordenskjold, *P.* 114, 612); or loose, red, flakes. When melted at about 190° and solidified, appears as very dark red, metal-like, crystalline mass. Very sol. in H_2O; $[CrO^3, Aq] = 1{,}900$ (Sabatier, *C. R.* 103, 267); S.G. of solution containing *x* p.c. CrO_3 at temperature *t* (Zettnow, *P.* 143, 474):—

x.	*t*.	S.G.
8·25	16°	1·0606
12·34	19·5	1·0957
19·33	19	1·1569
31·83	20·1	1·2026
37·77	22	1·3441
62·23	22	1·7028

Sol. in pure ether and in cold dilute alcohol (Zettnow, *l.c.*). Solution in water is acid and reacts with metallic oxides, &c., to form salts M_2CrO_4 (*v.* CHROMIC ACID). CrO_3 is easily deoxidised; by action of acids it yields chromic salts CrX_3, and gives up O.

Reactions.—CrO_3 is very easily reduced. **1.** CrO_3Aq is reduced by *hydrogen* (Ludwig, *A.* 162, 47).—2. Amorphous *phosphorus* heated to 200° forms CrO_2; P dissolves in CrO_3Aq forming an acid phosphate of Cr (Oppenheim, *Bl.* [2] 1, 165).—3. *Potassium* or *sodium* reduces CrO_3 on heating, probably to Cr.—4. *Sulphur* forms Cr_2S_3 and SO_2 (Moissan, *A. Ch.* [6] 5, 568).—5. Heated with *sulphydric acid*, Cr_2S_3, H_2O, and S are formed (Harten, *A.* 37, 350).—6. With *haloid aqueous acids*, halogen is evolved and CrX_3 formed.—7. *Sulphurous anhydride* has no action at 100°; at 180° CrO_2 and SO_3 are formed (Traube, *A.* 66, 103); SO_2Aq and CrO_3Aq form at first H_2SO_4Aq and CrO_2, and then Cr_23SO_4Aq. 8. *Nitric oxide* reduces CrO_3 to Cr_2O_3 (Reinsch, *J. pr.* 28, 391; Wöhler, *A.* 34, 236).—9. *Arsenious oxide* forms Cr_2O_3 and H_3AsO_4Aq with CrO_3Aq.—10. *Ammonia* forms Cr_2O_3, H_2O, and N; light is produced.—11. *Phosphoric chloride* forms CrO_2Cl_2 and $POCl_3$ (Schiff, *A.* 106, 116).—12. *Ferric chloride* heated with CrO_3 forms Fe_2O_3 and CrO_2Cl_2 (Geuther, *A.* 106, 239).—13. Heated with violet *chromic chloride* CrO_2Cl_2 and Cr_2O_4 are formed (Geuther, *A.* 118, 69).—14. CrO_3Aq is reduced to Cr_2O_3 by *stannous chloride*, $SnCl_4$ and SnO_2 being formed.—15. Cold conc. *sulphuric acid* dissolves CrO_3 (it is said to be quite insoluble in very conc. acid with 16–17 p.c. H_2O added); a compound $CrO_3.H_2SO_4$ is probably formed (*v. Combinations*, No. 2), but on heating, Cr_23SO_4, or a basic Cr sulphate ($4Cr_2O_3.6SO_3.7H_2SO_4$ according to Cross a. Higgins, *C. J.* 41, 113), is formed, with evolution of O.—16. CrO_3Aq is reduced by *electrolysis* to Cr, Cr_2O_3, and O; 30,225 gram-units of heat are produced (Favre, *C. R.* 73, 890 a. 936; Geuther, *A.* 99, 314; Buff, *A.* 110, 257).—17. *Iodine* dissolves in conc. CrO_3Aq; the products are uncertain (Walz, *C. N.* 26, 245).—18. *Oxygen*, *ozone*, or pure dry *chlorine*, has no action on CrO_3 (Moissan, *A. Ch.* [6] 5, 568).—19. Heated with carbon disulphide to 180° a little COS is formed (Armstrong, *B.* 2, 713).—20. Very many *carbon compounds*, *e.g.* C_2H_4, C_2H_2, C_2H_6O, $C_2H_2O_4$, $C_6H_5.CH_3$, &c., are oxidised by CrO_3Aq: a mixture of $K_2Cr_2O_7$, H_2SO_4, and H_2O is generally employed.

Combinations.—1. With *water* to form H_2CrO_4 (Moissan, *A. Ch.* [6] 5, 568; *v.* CHROMIC ACID, under CHROMIUM, ACIDS OF).—2. According to Bolley (*A.* 56, 113) CrO_3 combines with *sulphuric acid* to form $CrO_3.H_2SO_4$ (? H_2CrSO_7); it is prepared by adding crystallised CrO_3 to conc. H_2SO_4, little by little, until no more is dissolved, and after some days collecting the brown solid matter and drying on a porous plate. 3. Schröder describes a compound with *sulphuric anhydride* $CrO_3.3SO_3$ (*P.* 59, 616; *v.* also Gay-Lussac, *S.* 32, 447; Fritzsche, *J. pr.* 27, 252). 4. Moissan (*C. R.* 97, 96) says that the body produced by the action of H_2O_2Aq on CrO_3Aq, usually regarded as a higher oxide than CrO_3, is really a compound of CrO_3 and H_2O_2, viz. $CrO_3.H_2O_2$ (*v. infra*).

IV. OTHER OXIDES OF CHROMIUM.

(i) The oxide Cr_3O_4—corresponding to Fe_3O_4, Ni_3O_4, and Co_3O_4—is said to be produced by the action of air-free KOHAq on $CrCl_2Aq$, immediate washing the pp. with boiling water and drying *in vacuo*; it is scarcely soluble in acids; when heated it takes up O forming Cr_2O_3 (Péligot, *A. Ch.* [3] 12, 539). By electrolysing $CrCl_2Aq$, containing $CrCl_3$, under special conditions, Bunsen obtained a black, amorphous, powder, insol. acids, oxidised by heating in air to Cr_2O_3 (*P.* 91, 619). This powder seems to have been either a mixture or a compound of CrO and Cr_2O_3 (but *v.* Geuther, *A.* 118, 66).

(ii) When CrO_3 is heated in air, or O, to a little over 200° (Geuther a. Merz, *A.* 118, 62), or when a rapid stream of CrO_2Cl_2 vapour is passed through a tube heated to above 200°, but not to redness (Wöhler, *A.* 111, 117), small, lustrous, dark-violet, trimetric prisms, S.G. about 4, are obtained. According to Wöhler the composition is Cr_3O_5; according to Geuther Cr_5O_9. These crystals are distinctly magnetic, but lose their magnetism by heating in air; when strongly heated Cr_2O_3 is formed. Insoluble in all acids including *aqua regia*; slowly acted on by conc. boiling KOHAq; decomposed by molten KOH to Cr_2O_3 and K_2CrO_4.

Traube (*A.* 66, 108) describes two oxides Cr_8O_{11} and Cr_5O_{12}; but the existence of these as definite compounds is doubtful.

(iii) When H_2O_2Aq is added to CrO_3Aq, or when a dilute, strongly acid, solution of BaO_2 in HClAq is added to $K_2Cr_2O_7Aq$, a deep-blue colour is produced in the solution (Barreswill, *A. Ch.* [3] 20, 364); this colour quickly disappears, O being evolved (Schönbein, *P.* 108, 471). The blue compound is more stable in ethereal than aqueous solution. BaO_2 is added to HClAq, ether (free from alcohol) is then added, and then $K_2Cr_2O_7Aq$ drop by drop with constant shaking; the ether becomes deep azure blue, it is free from HCl and H_2SO_4. The ethereal solution evolves O when evaporated, and CrO_3 remains (Aschoff, *J. pr.* 81, 401 a. 487). Ferrous salts are oxidised by the blue ethereal liquid; alkalis decompose it to alkali chromates and O; it is also decomposed by P_2O_5, $CaCl_2$, MnO_2, Pb_3O_4, HgO, Na, and by acids and bases (Moissan, *C. R.* 97, 96; *v.* also Martinon, *Bl.* [2] 45, 862). Certain alkaloids, *e.g.* strychnine and quinine, seem to form compounds with the blue-coloured body; these compounds are, however, unstable. According to Aschoff (*J. pr.* 81, 401 a. 471), for the formation and complete decomposition of the blue-coloured compound H_2O_2 reacts with $K_2Cr_2O_7$ in the ratio $5H_2O_2:K_2Cr_2O_7$; assuming the blue compound to be an oxide of Cr with the composition Cr_2O_7, the reaction in question might be represented as

(1) $K_2Cr_2O_7Aq + H_2O_2Aq + 2HClAq =$
$2KClAq + 2H_2OAq + Cr_2O_7Aq$;

(2) $Cr_2O_7Aq + 6HClAq + 4H_2O_2Aq =$
$Cr_2Cl_6Aq + 7H_2OAq + 8O$. Fairley (*C. N.* 33, 237) supposes that the blue compound is $CrO_6.3H_2O$. Moissan (*C. R.* 97, 96) obtained an ethereal solution of the dark-blue compound containing 5 p.c. Cr; at −20° *in vacuo* deep indigo blue, oily, drops were produced; by the action of Na, H was evolved, and by gently warming O was evolved; the volumes of these gases obtained corresponded with those required by the formula $CrO_4.H_2O_2$. The blue compound cannot be obtained by the action of ozone on CrO_3Aq; it is formed during electrolysis only when H_2O_2 is also produced (Moissan, *l.c.*).

Chromium, oxychlorides of. Various oxychlorides, or perhaps compounds of Cr_2O_3 and $CrCl_3$, are obtained by evaporating $CrCl_3Aq$ at different temperatures (p. 167). Of the compounds theoretically derivable from $CrO_2(OH)_2$ by replacing OH by Cl, viz. CrO_2OHCl and CrO_2Cl_2, the second only is known; the first would react as an acid, the K salt of this acid is known (*v.* *Chloro-chromates* under CHROMIUM, ACIDS OF, p. 157). CrO_2Cl_2 easily parts with O and Cl; heated in a closed tube $Cr_3O_6Cl_2$ is produced.

I. CHROMYL CHLORIDE CrO_2Cl_2 (*Chlorochromic acid. Chlorochromic anhydride*). Mol. w. 155·06. (115·9°) (Thorpe, *C. J.* 37, 362). S.G. $\frac{0}{4}$ 1·9617 (Thorpe, *l.c.*). V.D. 78.

Formation.—1. Equal parts CrO_3 and $FeCl_3$ are heated together in a retort (Geuther, *A.* 106, 239).—2. CrO_3 and $CrCl_3$ are heated together in the ratio $2CrCl_3:3CrO_3$ (Geuther, *A.* 118, 69).—3. 1 part CrO_3 and 2 parts PCl_5 are heated together (Schiff, *A.* 106, 116).—4. HCl is passed into conc. H_2SO_4 containing CrO_3 in suspension (*B.* 10, 1041).—5. HCl is passed over CrO_3 (Moissan, *A. Ch.* [6] 5, 568).

Preparation.—10 parts NaCl are fused with $12\frac{1}{2}$ parts $K_2Cr_2O_7$; the fused mass in fair-sized pieces is placed in a retort connected with a well-cooled condenser, and 25 parts fuming H_2SO_4 are added. The reaction proceeds without heating (Thomson, *T.* 1827. 159; Berzelius, *B. J.* 6, 131; Wöhler, *P.* 33, 343; Etard, *A. Ch.* [5] 22, 218). About 70 p.c. of the theoretical yield of CrO_2Cl_2 is obtained; part of the CrO_2Cl_2 is decomposed by the acid to CrO_3, Cl, and Cr_23SO_4 (Etard, *l.c.*). The distillate is redistilled several times in CO_2.

Properties.—A dark-red, mobile, liquid; fumes much in the air; dissolves Cl and I in large quantities. The vapour absorbs all the light from a luminous flame except a narrow band in the red (Stoney a. Reynolds, *P. M.* [4] 41, 291). If the vapour is mixed with O and passed into a Bunsen lamp a violet flame is produced, showing lines in the violet, green, yellow, orange, and red, part of the spectrum (Gottschalk a. Drechsel, *J. pr.* 89, 473). CrO_2Cl_2 is best kept in sealed glass tubes.

Reactions.—1. Easily parts with O and Cl; acts as an energetic oxidiser and chlorinating agent, *e.g.* oxidises P, S, Hg, alcohol, turpentine, &c., oxidises and chlorinates C_6H_6 (forming $C_6HCl_3O_2$), $C_{10}H_8$ (forming $C_{10}H_4Cl_2O_2$) &c. (*v.* Liebig, *P.* 21, 359; Schrötter, *A.* 37, 148; Heintze, *J. pr.* [2] 4, 211; Carstanjen, *J. pr.* [2] 2, 51).—2. Heated with PCl_3, $POCl_3$, or PCl_5, $CrCl_3$ and Cr_2O_3 are formed with evolution of Cl (Casselmann, *A.* 98, 213; Schiff, *A.* 102, 111; Weber, *P.* 107, 375; Cronander, *B.* 6, 1466).—3. With *water*, CrO_3Aq and HClAq are formed with production of much heat.—4. Decomposed, giving crystalline CrO_3, when passed through a *warm tube* (Wöhler, *P.* 33, 331).—5. Heated in a closed tube to 180°, $Cr_3O_6Cl_2$ and Cl are formed (Thorpe, *C. J.* [2] 8, 31).—6. *Iodine* dissolves in CrO_2Cl_2; on heating $Cr_3O_6Cl_2$ and ICl are formed (Macivor, *C. N.* 28, 138).—7. Reacts with KClAq to form $CrO_2.OK.Cl$ (*q. v.* under CHROMATES) and HClAq (Péligot, *A. Ch.* 52, 267).—8. With K_2CrO_4Aq combines to form $CrO_2.OK.Cl$ (Geuther, *A.* 106, 240).—9. Burns in dry NH_3 to form NH_4Cl and CrO_2 (Rideal, *C. J.* 49, 367).

II. TRICHROMYL CHLORIDE $Cr_3O_6Cl_2$ (*Chromium chromato-chloride*). Mol. w. unknown.

Formation.—1. Potassium chlorochromate,

$CrO_2OK.Cl$ is heated with conc. H_2SO_4; CrO_2Cl_2 and $Cr_3O_6Cl_2$ are produced together (Zettnow, *P.* 143, 328).—2. I is dissolved in CrO_2Cl_2, and the product is distilled (Macivor, *C. N.* 28, 138).

Preparation.—CrO_2Cl_2 is heated in a closed tube for several hours to 180°, and the residue is heated in dry CO_2 to 120° to remove unchanged CrO_2Cl_2 (Thorpe, *C. J.* [2] 8, 31).

Properties and Reactions.—A black, amorphous, very deliquescent powder; heated in air, O, Cl, and Cr_2O_3 are formed; easily reduced by H to Cr_2O_3 with evolution of O and Cl; dissolves in HClAq, Cl is evolved, and $CrCl_3Aq$ remains; aqueous solution also gives off Cl on heating.

III. OXYCHLORIDES from $CrCl_3Aq$ (Moberg, *J. pr.* 29, 175; Lœwel, *J. pr.* 37, 38; Péligot, *J. pr.* 37, 475; Schiff, *A.* 124, 157; Ordway, *Am. S.* [2] 26, 197; Béchamp, *A. Ch.* [3] 56, 306; 57, 296). By evaporating $CrCl_3Aq$ at 120° a reddish residue, soluble in H_2O, agreeing with composition $Cr_2O_3.8CrCl_3.24H_2O$, was obtained; this heated to 150° left a reddish-grey powder, $Cr_2O_3.4CrCl_3.9H_2O(=Cr_2OCl_4.3H_2O)$; when more strongly heated, and water added, a residue remained, $2Cr_2O_3.2CrCl_3(=CrOCl)$ (Moberg). Cr_2OCl_4 was also obtained by heating $CrCl_3.xH_2O$ to 150°–260°, and by long-continued digestion of $Cr_2O_3.xH_2O$ with cold dilute HClAq (Lœwel; Péligot).

$CrOCl.3H_2O$ was obtained by adding BaO_2H_2Aq to $CrCl_3Aq$ until the pp. no longer dissolved, evaporating, treating the residue with alcohol ($BaCl_2$ remained), evaporating to dryness at 100° and drying at 120° (Péligot); the same compound was obtained by boiling $CrCl_3Aq$ with $Cr_2O_3.xH_2O$ (Béchamp).

Chromium, oxyfluoride of, CrO_2F_2. Said to be obtained by reaction between $PbCrO_4$, CaF_2, and H_2SO_4 (*v.* Oliveri, *G.* 16, 218).

Chromium, phosphide of, CrP. Mol. w. unknown. S.G. 4·68.

Formation.—1. By strongly heating $CrPO_4$ with C (H. Rose, *P.* 34, 333).—2. By passing PH_3 over hot $CrCl_3$ (H. Rose, *l.c.*).

Preparation.—Pieces of P are placed in the closed end of a tube of very infusible glass; dry K_2CrO_4 is placed at a little distance from the P. The K_2CrO_4 is heated to redness; the P is then heated so that the vapour passes over the K_2CrO_4; much heat and light are produced during the reaction. The product is treated with H_2O, which dissolves out K phosphates and leaves the CrP (Martius, *A.* 109, 82).

Properties and Reactions.—A grey-black, crystalline, metal-like powder; insoluble in all acids; heated in O, burns to $CrPO_4$; heated in Cl, forms PCl_3 and $CrCl_3$; oxidised by molten KOH with evolution of H, and by molten $KClO_3$ with evolution of Cl.

Chromium, salts of. Compounds obtained by replacing H of acids by Cr. Two series of Cr salts exist; chromous salts CrX_2, and chromic salts CrX_3, where $X=Cl$ &c., $\frac{SO_4}{2}$ &c., $\frac{PO_4}{3}$ &c. The V. D. of two compounds of Cr, viz. CrO_2Cl_2 and $CrCl_3$, have been determined; from this, and the S.H. of Cr, the value for the atomic weight of the element is found to be 52·4: the simplest formulæ that can be given to the salts of Cr ($Cr=52·4$) are CrX_2 and CrX_3, but these formulæ do not necessarily represent the composition of gaseous molecules.

Chromous chloride, $CrCl_2$, is the starting-point for preparing most of the *chromous salts*; these salts are red or blue, and soluble in water; they very quickly absorb O, becoming chromic salts; they also absorb NO, and also C_2H_2 (Berthelot, *A. Ch.* [4] 9, 385). The most stable chromous salts at present known are the sulphate $CrSO_4.7H_2O$, blue crystals isomorphous with $FeSO_4.7H_2O$; the acetate $Cr(C_2H_3O_2)_2.H_2O$, red trimetric prisms; and the oxalate CrC_2O_4, yellow crystalline powder, more stable than any other chromous salt. (For more details of individual salts *v.* ACETATES, CARBONATES, BORATES, OXALATES, PHOSPHATES, SULPHATES, SULPHITES; also CHROMOUS BROMIDE, CHLORIDE, HYDROXIDE, SULPHIDE.)

The normal *chromic salts*, CrX_3, are obtained by dissolving $Cr_2O_3.xH_2O$ in acids, or by double decomposition from soluble chromic salts obtained in this way; these salts may be regarded as derived from the hydroxide $Cr_2O_6H_6$. Numerous basic salts also exist, many derived from the hydroxide $Cr_2O.O_4H_4$ (*v.* CHROMIC HYDROXIDES). The starting-point in the preparation of chromic salts is usually $K_2Cr_2O_7$; a solution of this salt is heated with HClAq, or H_2SO_4Aq, and a reducing agent (commonly alcohol or SO_2Aq); $CrCl_3Aq$ or Cr_23SO_4Aq is thus obtained; addition of NH_3Aq pps. $Cr_2O_3.xH_2O$, from which the chromic salts are obtained by the action of acids. Very many chromic salts exist in two forms, one violet to red, the other green. In some cases both varieties are known in the solid form and with the same composition, *e.g.* red and green Cr_23SO_4; in other cases only a violet salt is known in crystals, but a green solution is obtainable from this. Aqueous solutions of most of the violet salts when boiled become green; many of these solutions become red or violet again on cooling, sometimes only after standing a long time. Only the violet, or red, solutions yield crystalline salts; the green solutions give amorphous, gummy solids on evaporation. Various hypotheses have been suggested to account for these colour-changes. The change does not seem to be due to hydration and dehydration (Schrötter, *P.* 53, 513), as dehydrating agents do not effect the change from red to green (Doyer van Cleeff, *J. pr.* [2] 23, 58). The experiments of Krüger (*P.* 61, 218), Siewert (*A.* 126, 94), and Doyer van Cleeff (*J. pr.* [2] 23, 58) seem to show that in some cases at any rate, *e.g.* chrome-alum, the normal violet salt is partially decomposed, on boiling, into basic salt and acid, and that on cooling the normal (violet) salt is re-formed. Van Cleeff dialysed a green solution of chrome-alum, and found the dialysate to contain free H_2SO_4, and the liquid in the dialyser excess of Cr_2O_3; he also dialysed a violet solution of chrome-alum, and found the same composition in the liquid, both inside and outside the dialyser. The same chemist also found that the violet solution became green on addition of a little KOH, NaOH, NH_3, or alkaline carbonate; and that a little acid sufficed to reproduce the violet colour. For details of individual salts *v.* the arts. CARBONATES, BORATES, NITRATES, SULPHATES, &c. &c.

Chromium, selenides of, CrSe and Cr_2Se_3. Moissan (*C. R.* 90, 817) describes these compounds as black powders; Cr_2Se_3 obtained by heating Cr_2O_3 in Se vapour, or $CrCl_3$ in H_2Se; CrSe obtained by heating Cr_2Se_3 in H, or $CrCl_2$ in H_2Se.

Chromium, sulphides of, Cr and S combine when heated together to form Cr_2S_3; the same sulphide is produced by heating Cr_2O_3, $CrCl_3$, CrO_3, &c., in H_2S. No sulphide of Cr, but only $Cr_2O_3.xH_2O$, is produced by the action of H_2S, alkali sulphides, &c., on solutions of Cr salts. Cr_2S_3 is reduced by H to CrS. The sulphide Cr_3S_4 has also been obtained. Phipson (*C. N.* 4, 125) stated that a heptasulphide Cr_2S_7 exists; but this has been disproved (*v.* Bender, *B.* 20, 756). Compounds of Cr_2S_3 with ZnS, MnS, FeS, &c., are obtained indirectly, *e.g.* $ZnS.Cr_2S_3$; Cr_2S_3 therefore resembles Cr_2O_3 inasmuch as it acts as a feebly salt-forming sulphide towards more positive sulphides.

I. CHROMIC SULPHIDE Cr_2S_3. Mol. w. unknown. S.G. 3·77 (Schafarik, *J.* 1863. 225). *Preparation.* Dry H_2S is passed over Cr_2O_3 heated to about 440°; the product is powdered and again heated in H_2S, and finally washed with H_2O, and dried at 100° (Moissan, *C. R.* 90, 817). Cr_2S_3 is also obtained by the action of H_2S on hot $CrCl_3$ (Liebig, *P.* 21, 359); or on $Cr_2 3SO_4$ (Traube, *A.* 66, 87); or by strongly heating Cr_2O_3 in CS_2 (H. Rose); or $K_2Cr_2O_7$ in CS_2 (Schafarik, *J. pr.* 90, 9; Müller, *P.* 127, 404); or by heating $Cr_2O_3.xH_2O$ with S, in absence of air (Berzelius).

Properties and Reactions.—Brown-black, lustrous powder, steel-grey if fused; not attacked by acids, except HNO_3Aq and *aqua regia*, which dissolve it. Heated in air, gives SO_2 and Cr_2O_3; in Cl, gives S_2Cl_2 and $CrCl_3$; with molten KNO_3, K_2CrO_4 and K_2SO_4 are formed; heated in H, gives off H_2S and S, and CrS remains (Moissan, *C.R.* 90, 817).

Combinations.—Cr_2S_3 is not acted on by KOHAq or K_2SAq; but by heating K_2CrO_4 with K_2CO_3 and S, and washing with water, greenish-black crystals (S.G. 2·79) are obtained, which are easily soluble in HNO_3Aq; these are probably a compound of K_2S and Cr_2S_3 (Kopp, *C. R.* 19, 1156; Schafarik, *J. pr.* 90, 9). By heating $Cr_2O_3.xH_2O$, $MO.xH_2O$ (or $M_2O_3.xH_2O$), and S, in S vapour, and then in CO_2 until no more S is given off, Gröger (*Sitz. W.* 81 [2nd part], 531) obtained compounds of the form $MS.Cr_2S_3$; M = Zn, Fe, Mn. (*v.* CHROMIUM, THIOACID OF).

II. CHROMOUS SULPHIDE CrS. Mol. w. unknown. A black powder, produced by heating Cr_2S_3 in H, or by heating $CrCl_3$ in H_2S at 440° (Moissan, *C. R.* 90, 817). Unchanged by heating in absence of air; heated in air Cr_2O_3 and SO_2 are formed; heated in Cl, gives $CrCl_3$; scarcely acted on by acids.

III. CHROMIUM TETRASULPHIDE Cr_3S_4. Mol. w. unknown. A greyish-black powder; insoluble in H_2O; slightly soluble in conc. HClAq, easily in conc. HNO_3Aq. Prepared by heating dry Cr_2O_3 thoroughly mixed with excess of well-powdered S in H until no more S is given off, again mixing with S and again heating in H (Gröger, *Sitz. W.* 81 [2nd part], 531).

Chromium, sulphocyanides of, and derivatives of these compounds, *v.* SULPHOCYANIDES, under CYANIDES

Chromium, thioacid of. No thioacid of Cr is known; but Cr_2S_3 behaves towards some more positive metallic sulphides as a salt-forming sulphide; in this respect it may be regarded as the thioanhydride of *hypothetical thiochromous acid*, $H_2Cr_2S_4$. Gröger (*Sitz. W.* 81 [2nd part], 531) obtained the **thiochromites** $ZnCr_2S_4$, $FeCr_2S_4$, and $MnCr_2S_4$, by heating mixtures of Cr hydroxide and hydroxide of Zn, Fe, or Mn, with S, for some time, then powdering and heating in S vapour for several hours, and finally heating in CO_2 until S was no longer given off. These thiochromites are dark-brown or black powders, insoluble in H_2O and HClAq, soluble in HNO_3Aq and *aqua regia*. M. M. P. M.

CHROMIUM GROUP OF ELEMENTS.—*Chromium, Molybdenum, Tungsten, Uranium.*—These four metals were discovered towards the end of the eighteenth century. None of them is found in the free state in nature, and the minerals in which their salts occur are all comparatively rare. Chromium was obtained in 1797 by Vauquelin from a mineral now known to consist chiefly of lead chromate; in 1782 Hjelm prepared molybdenum from an acid earth-like compound, which Scheele had obtained four years earlier from molybdenum-glance, a substance until then supposed to be the same as galena; three years after the preparation of molybdenum a new metal was obtained by the brothers d'Elhuyar, by deoxidising an acid which they had prepared from the mineral wolframite. This acid was shown to be identical with that which Scheele had made in 1781 from the Swedish mineral tungstein, hence the new metal was called tungsten, or by some chemists wolfram. Uranium was the name given by Klaproth to a new metal obtained by him 1789 from pitchblende.

Chromium, molybdenum, and tungsten are obtained by reducing the oxides of these metals by carbon at a high temperature; uranium is prepared by removing chlorine from the chloride by means of sodium. These metals are very hard and very infusible; uranium is fairly malleable; the others are brittle. The table on p. 169 presents the prominent physical and chemical properties of the chromium metals.

General formulæ and character of salts.

MO, M_2O_3, MO_2, MO_3; MS, M_2S_3, MS_2, MS_3, MS_4; MCl_2, MCl_3, MCl_4, MCl_5, MCl_6; H_2MO_4, $H_2M_2O_7$, &c. The lowest oxides, MO, are scarcely known; hydrates of these oxides, when M = Cr or Mo, appear to exist; a few chromous salts, *e.g.* $CrSO_4 7H_2O$, exist, but are unstable, and easily become chromic salts. Sesquioxides, M_2O_3, of Cr and Mo are known; the former dissolves in acids with production of well-marked salts, the chromic salts, $Cr_2 3SO_4$, $Cr_2 6NO_3$, $Cr_2 2PO_4$, &c.; the latter is easily oxidised to MoO_2, when moist it dissolves in acids, but no definite salts have been obtained from such solutions. Dioxides, MO_2, of all the metals of the group have been prepared: of these, CrO_2 is the least stable towards heat or the action of acids, it parts with oxygen at 300°, and dissolves in acids apparently without deoxidation, but without producing definite salts; MoO_2 and WO_2 also dissolve in acids and produce salts, which, however, have scarcely been obtained in definite crystalline form; the solutions of MoO_2 readily take up oxygen from the air; both oxides, when heated, are oxidised to MO_3; UO_2 dissolves in acids to form a series of uranous salts, *e.g.* $U(SO_4)_2$, which are fairly easily oxidised to uranyl salts, *e.g.* UO_2SO_4; when this oxide is heated it becomes U_3O_8. The oxides MO_3 are all anhydrides; the mono-hydrated oxides $MO_3H_2O(=H_2MO_4)$ act as dibasic acids, forming salts X_2MO_4; several series of salts derived from more complex hydrates of MO_3 are also known, *e.g.* $X_2M_2O_7$, $X_2M_3O_{10}$, $X_2M_4O_{13}$, &c., in the case of each metal except Cr these di- tri- or tetra-salts are more distinctly marked than the salts X_2MO_4. The anhydride CrO_3 combines with some normal salts, *e.g.* $K_2CrO_4CrO_3$, and also with a few anhydrides, *e.g.* $CrO_3.3SO_3$; when dissolved in warm acids it forms chromic salts (Cr_23SO_4, &c.) with evolution of oxygen. The anhydrides MoO_3 and WO_3 form a series of complex compounds with anhydrides and water; *e.g.*

$P_2O_5.20MoO_3.38H_2O$; $SiO_2.12MoO_3.26H_2O$;
$P_2O_5.24WO_3.6H_2O$; $P_2O_5.22WO_3.6H_2O$, &c. &c.;

MoO_3 also combines with SO_3 to form MoO_3SO_3 (? MoO_2SO_4). The anhydride UO_3 dissolves in acids to form uranyl salts, *e.g.* UO_2SO_4, $UO_2(NO_3)_2$, &c., which are more stable than the uranous salts derived from UO_2. The metals of the chromium group form several other oxides intermediate between those briefly described, *e.g.* Cr_5O_9 intermediate between Cr_2O_3 and CrO_2, W_3O_8 and W_4O_{11} between WO_2 and WO_3, U_2O_5 and U_3O_8 between UO_2 and UO_3: there are also indications of the existence of a more oxidised oxide than CrO_3,

	CHROMIUM.	MOLYBDENUM.	TUNGSTEN.	URANIUM.
Atomic Weights.	52·4.	95·9.	183·6.	239.
	One or more compounds of each element have been gasified; specific heats have been directly determined. Molecular weights unknown.			
Melting points.	Above m.p. of Pt (which is 2000°–2500°).	Infusible at full white heat.	Softens and agglomerates at white heat.	A full red-heat.
Spec. grav. (approx.).	6·5 6·8.	8·5–8·6.	18·2–19·2.	18·4–18·7.
Specific heats.	0·10 (? too low).	0·066	0·0334.	0·028.
Atom. weight. / Spec. grav. (approx.).	7·7.	11·3.	9·7.	12·9.
Occurrence and preparation.	Occurs chiefly as chrome-ironstone, $FeO.Cr_2O_3$, in which FeO is more or less replaced by MgO &c., and Cr_2O_3 by Al_2O_3 &c.; also as lead chromate, &c.; not widely diffused; obtained by deoxidising Cr_2O_3 by C, or removing Cl from $CrCl_3$ by means of K or Zn, or by electrolysing a solution of $CrCl_2$ containing $CrCl_3$.	Occurs in small quantities as oxide and sulphide, also as lead or cobalt molybdate; obtained by reducing the oxide or chloride by H, or the oxide by C or by KCN.	Occurs very sparingly as tungstate of Ca, of Fe and Mn, and of Pb, also as oxide; obtained by reducing the oxide or chloride in hydrogen.	Sparingly distributed as oxide in pitchblende, as uranite of Ca and of Cu, as carbonate of U and Ca &c.; obtained by reducing the chloride by means of sodium.
Physical properties.	Very hard; brittle; crystalline powder composed of small, brilliant, tin-white crystals (? rhombohedra); descriptions of properties differ considerably, probably the metal has not been obtained in approximate purity.	Ashen-grey powder, or, when compressed, a silver-like, lustrous, hard, brittle, infusible metal.	Resembles iron in colour and lustre; very hard, and brittle; also obtained as a brown amorphous powder; forms a very hard durable alloy with iron.	White, lustrous; hard, softer than steel; somewhat malleable, but cannot be beaten into thin plates; also obtained as a grey-black powder.

TABLE—*cont.*

	CHROMIUM.	MOLYBDENUM.	TUNGSTEN.	URANIUM.
Chemical properties.	Burns in stream of O; somewhat more stable in air than iron; heated in air becomes covered with very thin film of oxide; oxidised by molten KNO_3 or $KClO_3$, but not by molten Na_2CO_3; easily dissolved by dilute HClAq or H_2SO_4Aq, but not attacked by hot concentrated HNO_3Aq; combines easily with Cl and I when heated; decomposes steam slightly at a red heat; forms a well-marked cyanide $CrCy_3$. Replaces H of acids forming two series of salts; trioxide acts as an anhydride, forming chromic acid H_2CrO_4, from which many salts are obtained; Cr_2O_3 also forms salts (chromites) by heating with ZnO, &c. Atom of Cr is trivalent in $CrCl_3$.	Not oxidised in air at ordinary temperature, but burns at low red heat; unacted on by HCl, HF, or dilute H_2SO_4Aq; dissolves in conc. H_2SO_4; oxidised to MoO_3 by HNO_3Aq; oxidised by molten KOH, but not attacked by hot KOHAq; combines with Cl to form $MoCl_5$ when heated; also with Br to form $MoBr_2$ and $MoBr_4$, but not with I; forms a nitride (? Mo_3N_2) when $MoCl_5$ is strongly heated in NH_3. Salts in which H of acid is replaced by Mo scarcely known; MoO_3 acts as anhydride of H_2MoO_4, from which acid several series of salts are obtained; MoO_3 also combines with acid radicles, *e.g.* SO_3, P_2O_5, &c. Forms many oxyhaloid salts. Atom of Mo pentavalent.	Unchanged in ordinary air, but burns in air at red heat; combines with Cl only at a high temperature, to form WCl_6; dissolves in boiling conc. KOHAq to form K tungstate with production of H; oxidised to WO_3 by hot HNO_3Aq, H_2SO_4Aq, or HClAq; forms a nitridamide, $W_2N_2.W2NH_2$, by heating WCl_6 in NH_3. Does not appear to form salts by replacing H of acids; WO_3 is the anhydride of the acid H_2WO_4, which yields several series of salts; WO_3 also combines with acid radicles, *e.g.* SO_3, SiO_2, &c. Forms many oxyhaloid salts. Atom of W penta- and hexa-valent.	Slowly tarnishes in air; oxidised at 150°–200° in air, with evolution of light and sparks; combines with Cl or Br when heated to form UCl_4 and UBr_4; very slightly attacked by iodine vapour; heated in S vapour forms US_2; dissolves in warm dilute H_2SO_4Aq, with evolution of H, easily in HClAq, also in HNO_3Aq (when melted and cooled it is nearly insoluble in HNO_3); does not decompose water; a nitride (? U_3N_4) formed by heating UCl_4 mixed with NH_4Cl in NH_3. Forms two series of salts, uranous, *e.g.* $U(SO_4)_2$, and uranyl, salts, *e.g.* $UO_2(SO_4)$; UO_3 is the anhydride of H_2UO_4, from which several salts are derived, the most marked being $M_2U_2O_7$. Atom of U tetravalent.

(? Cr_2O_7), and the oxide UO_4 is said to have been obtained in the hydrated state.

The sulphides MS_3 (M = Mo, W) are acidic; sulpho-salts of the form H_2MS_4 are known.

Of the haloid compounds of these metals the following have been obtained as gases: $CrCl_3$, $MoCl_5$, WCl_5, WCl_6, UCl_4, UBr_4; the formulæ of these compounds represent the relative masses of their molecules. It is said that CrF_6 has also been prepared in the state of gas, but the evidence is very doubtful; the oxychloride CrO_2Cl_2 is an easily gasifiable body. Of the haloid compounds, $CrCl_3$ and UCl_4 are obtained by heating a mixture of Cr_2O_3 and C, or of UO_2 and C, in a stream of Cl gas; the former compound is very stable, the latter is reduced by strongly heating to UCl_4, which is again reduced to UCl_3 by heating in hydrogen. When Mo or W is heated in chlorine, in the one case $MoCl_5$ and the other case WCl_6 is produced, the other chlorides are obtained by heating these in H or in CO_2. All the metals of this group readily form oxyhaloid salts.

Chromic chloride is a particularly interesting compound; it exists in two varieties, one (green) soluble in water and scarcely crystallisable, the other (violet) obtainable in well-formed crystals, but with difficulty soluble in water; some other chromic salts seem also to exist in two varieties, *e.g.* the sulphate Cr_23SO_4 (*v.* CHROMIUM, CHLORIDES OF, p. 162). At least seven series of double compounds exist containing chromium, ammonia, and acid radicle (CHROMIUM, AMMONIO-SALTS OF, p. 158).

Of the four elements under consideration only Cr and U form well-marked salts by replacing the hydrogen of acids; these salts are not, however, analogous in composition or properties. The chromic salts are for the most part isomorphous with the salts of aluminium and the persalts of iron; the composition of these three groups of salts is also similar, *e.g.* M_23SO_4 where M = Cr, Al, or Fe. The uranyl salts—UO_2SO_4, &c.—to a certain extent stand by themselves, although we know of many so-called basic salts of chromium, iron, copper, &c., which resemble the uranyl salts in containing oxygen as well as metal and acid radicle.

Of the trioxides, MO_3, it may certainly be said that the most acidic in character is CrO_3, and the least acidic is UO_3; this is in accordance with the general rule that the higher oxides of the elements in the same *group* (as *group* is used in the nomenclature of the periodic law) become less acid in character as the group is ascended.

The four elements all show distinct analogies with S, Se, and Te, which occur in the same *group* but in odd *series*; *e.g.* existence of acids $MO_2(OH)_2$, and of anhydrides MO_3, &c.; but these three elements are more distinctly non-metallic in their properties than Cr, Mo, W, or U. The elements of the chromium group, as well as the three elements S, Se, and Te, show analogies with that element which is the first *odd series* member of the group, *viz.*, oxygen (*v.* CLASSIFICATION, p. 207; also OXYGEN GROUP OF ELEMENTS. For detailed accounts of the properties of the elements of this group and their chief compounds *v.* CHROMIUM, MOLYBDENUM, TUNGSTEN, URANIUM, and for the other salts of these metals, *v.* CARBONATES, NITRATES, SULPHATES, &c. M. M. P. M.

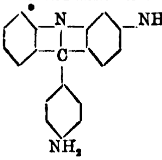
CHROMYL CHLORIDE CrO_2Cl_2 *v.* CHROMIUM, OXYCHLORIDES OF, p. 166.

CHRUSOCREATININE $C_5H_8N_2O$. A feebly alkaline substance said to occur in muscular tissue (Gautier, *Bl.* [2] 48, 18). Its solutions are ppd. by $HgCl_2$, by $ZnCl_2$, by iodine dissolved in aqueous KI, and by sodium phosphomolybdate. It forms a deliquescent hydrochloride and a crystalline platinochloride.

CHRYSAMMIDIC ACID *v.* TETRA-NITRO-OXY-AMIDO-ANTHRAQUINONE.

CHRYSAMMIC ACID *v.* TETRA-NITRO-DI-OXY-ANTHRAQUINONE.

CHRYSANILINE $C_{19}H_{15}N_3$ *i.e.*



Di-amido-phenyl-acridine.

[267°-270°]. A by-product in the manufacture of rosaniline. Discovered by E. C. Nicholson and investigated by Hofmann (*C. R.* 55, 817; *B.* 2, 379), who prepared methyl ethyl and phenyl derivatives.

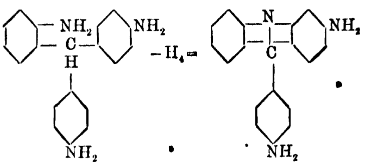
Preparation. — Commercial 'phosphine,' which is chrysaniline nitrate, is dissolved in hot water, cooled, and slowly added to dilute NaOH. The base separates as a bright yellow flocculent pp. It is dried at 100° and crystallised from benzene, which retains homologues in the mother liquid (O. Fischer a. G. Körner, *A.* 226, 177; *B.* 17, 203).

Synthesis.—By oxidising *opp*-tri-amido-triphenyl-methane $[2:1]NH_2.C_6H_4.CH(C_6H_4.NH_2[4:1])_2$, which is obtained by reduction of the product of condensation of *o*-nitro-benzoic aldehyde with aniline.

Properties.—Golden plates (from benzene) $C_{19}H_{15}N_3,C_6H_6$. The benzene of crystallisation is easily expelled. Golden needles of $C_{19}H_{15}N_3$ 2aq (from alcohol). Much less soluble in alcohol than its homologues. When pure it does not clot together when heated with NaOH. In small quantities it may be distilled without decomposition. It dyes wool and silk yellow.

Reactions. — 1. Heated with conc. HCl (8 vols.) at 170°, NH_2 is exchanged for OH and, on cooling, large red prisms of the hydrochloride of chrysophenol separate. These dissolve in NaOHAq, but on exactly neutralising, chrysophenol $C_{19}H_{14}N_2O$, separates as an orange pp., sl. sol. water, ether, or benzene, but v. sol. alcohol. From dilute alcohol it crystallises with 2aq. It is a yellow dye and a strong base, forming acid and neutral salts. It is insol. aqueous Na_2CO_3, but sol. aqueous NaOH (O. Fischer a. G. Körner, *A.* 226, 181).—2. By diazotisation and treatment with alcohol it is converted into phenyl-acridine. Chrysaniline (10 g.) dissolved in H_2SO_4 (50 g.) and water (4 g.) is well cooled and treated with nitrous acid gas in excess. The product (containing the diazo-sulphate) is slowly poured into boiling alcohol (600 g.). The alcohol is distilled off and the residue mixed with water and distilled with steam at 200°-250°. Phenyl-acridine [181°] passes over. 3g. pure chrysaniline gave 1 g. phenyl-acridine, or 40 p.c. of the theoretical yield.—3. MeI gives $C_{20}H_{16}Me_2N_3I_2$, which separates from water in red needles. NH_3 converts it into $C_{20}H_{15}Me_2N_3I$, whence Ag_2O forms $C_{20}H_{14}Me_3N_3$, a brown amorphous powder. EtI acts in the same way.

Formation in the rosaniline melt: This can be explained by two hypotheses: (1) That in the condensation of *p*-toluidine (1 mol.) with 2 mols. of aniline, together with the ordinary para-condensation producing rosaniline, a condensation simultaneously takes place which is partly ortho and produces *o*-di-*p*-tri-amido-methane, which by further oxidation yields chrysaniline—



(2) That *o*-di-*p*-tri-amido-methane is produced by condensation of 1 mol. of *o*-toluidine with 2 mols. of aniline. This latter hypothesis is the most probable and is supported by the above-mentioned synthesis (Fischer a. Körner, *B.* 17, 203).

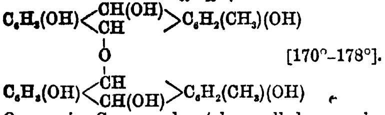
Salts. — B'2HCl. — B'2HCl aq. — B'HCl. — $B'HNO_3$.—$B'2HNO_3$.

Picric acid compound $B'(C_6H_2(NO_2)_3OH)_2$ aq (at 100°). Red needles.

Di-acetyl-derivative $C_{19}H_{11}N(NHAc)_2$.—Microscopic needles, dissolves in alcohol with a blue fluorescence, nearly insol. water. It is nearly as strong a base as chrysaniline itself and forms salts which greatly resemble the corresponding salts of chrysaniline.—B'HCl: soluble yellow microscopic needles, dyes wool and silk yellow. — $B'HNO_3$: sparingly soluble crystalline pp. (Anschütz, *B.* 17, 433).

CHRYSANISIC ACID *v.* DI-NITRO-AMIDO-BENZOIC ACID.

CHRYSAROBIN $C_{30}H_{26}O_7$ *i.e.*



$$\begin{array}{c} C_6H_3(OH)\left<\begin{array}{l}CH(OH)\\CH\end{array}\right>C_6H_2(CH_3)(OH)\\ | \\ O \\ | \\ C_6H_3(OH)\left<\begin{array}{l}CH\\CH(OH)\end{array}\right>C_6H_2(CH_3)(OH)\end{array}$$

[170°–178°].

Occurs in Goa powder (also called arrarobo powder) to the extent of about 70 p.c., from which it is extracted with C_6H_6. Small yellow leaflets, m. sol. benzene, $CHCl_3$, and acetic acid, sl. sol. alcohol or ether, insol. water. Insol. NH_3Aq (difference from chrysophanic acid). By leading air into the solution in KOH, chrysophanic acid is formed: $C_{30}H_{26}O_7 + 2O_2 = 2C_{15}H_{10}O_4 + 3H_2O$. By distillation with zinc dust it yields methylanthracene.

Di-acetyl derivative. Light yellow leaflets.

Tetra-acetyl derivative [228°–230°]. Yellowish prisms; sl. sol. alcohol with a blue fluorescence. By oxidation with CrO_3 it gives di-acetyl-chrysophanic acid (Liebermann a. Seidler, *B.* 11, 1603; *A.* 212, 29; *cf.* De Silva, *Ph.* [3] 5, 723; Holmes, *Ph.* [3] 5, 801).

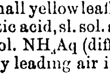
CHRYSATIC ACID $C_{21}H_{20}N_6O_{19}$ (Mulder, *J. pr.* 48, 16; *A.* 72, 289) or $C_{10}H_{12}N_4O_9$ (Schunck, *A.* 65, 240). An acid obtained by heating chrysammic acid with aqueous KOH. Sol. water.

CHRYSATROPIC ACID $C_{12}H_{10}O_5$. [202°]. S. (hot water) 1·3. An acid extracted by ether from an acidified infusion of the root or leaves of *Atropa belladonna* (Kunz, *Ar. Ph.* [3] 23, 722). Pale yellow trimetric prisms; may be sublimed. Sl. sol. cold water. Its alcoholic solutions exhibit green fluorescence.

CHRYSAZIN *v.* DI-OXY-ANTHRAQUINONE.

CHRYSAZOL *v.* DI-OXY-ANTHRACENE.

CHRYSENE $C_{18}H_{12}$ *i.e.*



$$\begin{array}{l}C_{10}H_6.CH\\ |\qquad\quad\; |\\ C_6H_4.CH\end{array}$$

. Mol. w. 228. [250°]. (above 360°). S. (alcohol) ·097 at 16°; ·17 at 78°; S. (toluene) ·24 at 18°; 5·39 at 100° (Bechi, *B.* 12, 1978). V.D. 7·95 (calc. 7·89).

Occurrence.—In coal-tar, in petroleum, and in the product of the dry distillation of fats, fir-wood, amber, and resins (Laurent, *A. Ch.* [2] 66, 136; Berthelot, *Bl.* [2] 7, 30; *J.* 1867, 605; Pelletier a. Walter, *A.* 48, 345; Williams, *J. pr.* 67, 248; Adler, *B.* 12, 1891; Prunier, *A. Ch.* [5] 17, 5).

Formation.—1. By passing naphthyl-phenyl-ethane through a red-hot tube (Graebe a. Bungener, *B.* 12, 1079).—2. The statement that chrysene is among the products of the passage of benzene through a red-hot tube has been contradicted (Berthelot, *J.* 1867, 605; *Bl.* [2] 7, 30; 22, 437; G. Schultz, *B.* 6, 415).—3. Among the products obtained by passing benzene-azo-benzene through a red-hot tube (Claus a. Suckert, *B.* 8, 87).

Properties.—Colourless scales or flat trimetric octahedra (from benzene); $a:b:c$ = 1:1·376:2·490; v. sl. sol. alcohol, sl. sol. ether and cold CS_2, m. sol. boiling benzene and HOAc. The solutions as well as the crystals exhibit deep reddish-violet fluorescence. Hot conc. H_2SO_4 forms a blue solution (Liebermann, *A.* 158, 299). CrO_3 in HOAc gives chrysoquinone (*q.v.*). By exhaustive chlorination with $SbCl_5$ it yields CCl_4, C_2Cl_6 and per-chloro-benzene (Merz a. Weith, *B.* 16, 2881).

Picric acid compound $C_{18}H_{12}C_6H_2(NO_2)_3OH$. Reddish-brown needles (from crude xylene) (Galletly, *C. N.* 10, 243). Decomposed by alcohol.

Di-nitro-anthroquinone compound $C_{18}H_{12}C_{14}H_6(NO_2)_2O_2$. [294°]. Formed by dissolving greenish-yellow commercial anthracene [208°] (50g.) in alcohol (5 litres) and adding HNO_3 (30g. of S.G. 1·4), and boiling. Red needles; v. sl. sol. alcohol, ether, and benzene. Tin and HCl reduce the di-nitro-anthraquinone, setting free pure chrysene, which may conveniently be prepared in this way.

Di-chloro-chrysene $C_{18}H_{10}Cl_2$. [267°]. From chrysene and Cl. Soft white needles (from benzene); v. sl. sol. alcohol; may be sublimed.

Tri-chloro-chrysene $C_{14}H_9Cl_3$. [above 300°]. Slender needles (from benzene). From chrysene and Cl at 170° (Schmidt, *J. pr.* [2] 9, 270).

Di-bromo-chrysene $C_{18}H_{10}Br_2$. [273°]. From Br and chrysene in CS_2. White needles (from benzene); v. sl. sol. all menstrua. Not attacked by alcoholic KOH below 180°. $K_2Cr_2O_7$ and H_2SO_4 oxidise it to chrysoquinone.

Nitro-chrysene $C_{18}H_{11}NO_2$. From chrysene and HNO_3 (S.G. 1·25) at 100°. [209°]. Thick prisms, grouped in stars (from benzene). May be sublimed; v. sl. sol. alcohol, ether, and CS_2.

Di-nitro-chrysene $C_{18}H_{10}(NO_2)_2$. [above 300°]. From chrysene and boiling HNO_3 (S.G. 1·3). Slender yellow needles (from HOAc). V. sl. sol. alcohol, ether, and benzene.

Tetra-nitro-chrysene $C_{18}H_9(NO_2)_3$. [above 300°]. From the preceding and fuming HNO_3. Yellow needles (from HOAc). Detonates above 300°.

Tri-bromo-di-nitro-chrysene $C_{18}H_7(NO_2)_2Br_3$. Yellowish-red needles. Sol. hot alcohol, less in C_6H_6 and ether. Prepared by the action of bromine on tetra-nitro-chrysene (Adler, *B.* 12 1894).

Isomeride of chrysene $C_{18}H_{12}$. [196]. A by-product in the preparation of diphenyl by action of sodium on bromo-benzene (Schultz, *A.* 174, 229). Long needles (from alcohol). Is perhaps triphenylene (Schmidt a. Schultz, *A.* 203, 135).

Isomeride of chrysene (?) $C_{18}H_{12}$. [186°]. A product of the action of Al_2Cl_6 on a mixture of naphthalene and phthalic anhydride (Ador a. Crafts, *C. R.* 88, 1355). Laminæ (from ether-alcohol). Its bromo-derivative melts at 112°.

CHRYSEUDIENE. A hydrocarbon, obtained in small quantity in the distillation of aluminum (β)-naphthol (Gladstone a. Tribe, *C. J.* 41, 16).

CHRYSIN $C_{15}H_{10}O_4$. *Chrysinic acid.* [275°]. S. (cold alcohol) ·66; (hot alcohol) 2. Occurs in the buds of *Populus nigra*, *P. pyramidalis*, and *P. balsamifera* (Piccard, *B.* 6, 884; 7, 888; 10, 176). The alcoholic extract, after successive treatment with lead acetate and H_2S, is evaporated, and the residue recrystallised from spirit and washed with alcohol, ether, CS_2, boiling water, and boiling benzene. The residue is heated to 275°, and crystallised from spirit. Bright yellow plates. Insol. water, nearly insol. benzene, CS_2, and chloroform. Aqueous alkalis form a yellow solution, but on boiling they split it up into phloroglucin, acetophenone, benzoic acid, and acetic acid. Lead acetate gives, in alcoholic solutions, a pp. soluble in excess.

Fe_2Cl_6 gives a violet colour in alcoholic solution.

Di-bromo-chrysin $C_{15}H_8Br_2O_4$. Formed by adding Br to an alcoholic solution of chrysin. Felted mass of silky needles.

Di-chloro-chrysin. Needles.

Di-iodo-chrysin $C_{15}H_8I_2O_4$. Formed by adding iodine and iodic acid to an alcoholic solution of chrysin.

Di-nitro-chrysin $C_{15}H_8(NO_2)_2O_4$. From chrysin and HNO_3. Large crystals (from hot HOAc or aniline). Forms an orange-red basic ammonium salt and a yellow acid ammonium salt.

Methyl derivative $C_{15}H_9MeO_4$. *Tecto-chrysin.* [164°]. From chrysin, MeI, and KOH dissolved in MeOH. Exists in poplar-buds together with chrysin, from which it may be separated by means of its much greater solubility in benzene and chloroform. It is much less soluble in alcohol than chrysin. Large sulphur-yellow monoclinic prisms (from alcohol); $a:b:c = 1{\cdot}54:1:1{\cdot}86$; $\beta = 53°$. Insol. alkalis. It forms a di-bromo-derivative.

Ethyl derivative $C_{15}H_9EtO_4$. [146°].

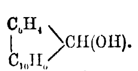
Iso-amyl derivative $C_{15}H_9(C_5H_{11})O_4$. [125°]. Its di-bromo- derivative crystallises in needles.

CHRYSOFLUORENE $C_{17}H_{12}$ *i.e.*

$\left.\begin{array}{l}C_6H_4\\ |\\ C_{10}H_6\end{array}\right\rangle CH_2$

[188°]. Silvery glistening tables. V. e. sol. ether, chloroform, and benzene, less sol. cold alcohol. Formed by heating chrysoketone with HI and P at 150°–160° (Bamberger a. Kranzfeld, *B.* 18, 1934).

Chrysofluorene alcohol



$\left.\begin{array}{l}C_6H_4\\ |\\ C_{10}H_6\end{array}\right\rangle CH(OH).$

[167°]. Formed by reduction of chrysoketone with zinc and HCl (B. a. K.). White silky needles or glistening plates. Sublimable. V. sol. alcohol, ether, and benzene, sl. sol. ligroin. Its alcoholic solution is turned blue by addition of H_2SO_4. Strong H_2SO_4 dissolves it with a reddish-violet colour.

CHRYSOGEN C. 94·3 to 95 p.c.; H 5·7 to 5 p.c. [280°–290°]. S. (cold benzene) ·04; (boiling benzene) ·2; S. (boiling HOAc) ·05; (cold HOAc) ·01. An orange-coloured hydrocarbon contained in small quantity in crude anthracene, and separated therefrom by repeated crystallisation from benzene (Fritzsche, *C. R.* 51, 910; *Bl.* [2] 6, 474; Prunier, *Bl.* [2] 31, 293). Orange tables with green lustre; may be sublimed. Conc. H_2SO_4 dissolves it without change. Small quantities colour white hydrocarbons yellow. Its solution is bleached by sunlight. It forms, with di-nitro-anthraquinone, a compound crystallising in olive needles with golden lustre.

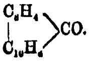
CHRYSOGLYCOLLIC ACID

$\left.\begin{array}{l}C_6H_4\\ |\\ C_{10}H_6\end{array}\right\rangle C(OH).CO_2H.$

White powder. Formed by boiling freshly precipitated amorphous chrysoquinone with alkalis (Bamberger a. Kranzfeld, *B.* 18, 1933).

CHRYSOIDINE *v. Benzene*-azo-*m-phenylene diamine.*

CHRYSOKETONE



$\left.\begin{array}{l}C_6H_4\\ |\\ C_{10}H_6\end{array}\right\rangle CO.$

[130°]. Glistening red needles. Scarcely volatile with steam. V. sol. the ordinary solvents. Formed by the oxidation of chrysoglycollic acid

$\left.\begin{array}{l}C_6H_4\\ |\\ C_{10}H_6\end{array}\right\rangle C(OH).CO_2H$

with $K_2Cr_2O_7$ and H_2SO_4 (Bamberger a. Kranzfeld, *B.* 18, 1933).

CHRYSO-NAPHTHAZINE $C_{28}H_{16}N_2$ *i.e.*

$C_{18}H_{10}\langle N_2 \rangle C_{10}H_6$.

Formed by mixing a solution of chrysoquinone in aqueous-alcoholic $NaHSO_3$ with an aqueous solution of naphthylene-*o*-diamine hydrochloride, sodium acetate, and acetic acid. Yellow microcrystalline powder (Liebermann a. Witt, *B.* 20, 2443).

CHRYSOPHANIC ACID *v.* Di-oxy-methyl-anthraquinone.

CHRYSOPHANIN. A white amorphous substance said to be contained in the aqueous decoction of senna leaves (Bourgoin, *C. R.* 73, 1449).

CHRYSOPHENOL $C_{19}H_{15}N_2O$. *Oxy-amido-phenyl-acridine.* Formed by heating chrysaniline with HCl under pressure at 180°, NH_2 being replaced by OH (Fischer a. Körner, *B.* 17, 205). Small yellowish-red needles (containing aq). Sl. sol. water, benzene, and ether, v. sol. alcohol and caustic alkalis. The hydrochloride and sulphate form sparingly soluble yellow crystals.

CHRYSOQUINONE $C_{18}H_{10}O_2$ *i.e.*

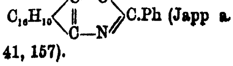
$\begin{array}{l}C_{10}H_6-CO\\ |\qquad\quad\ \ |\\ C_6H_4-CO\end{array}$

or

$\begin{array}{l}C_{10}H_6.C.O\\ |\qquad\ \ \|\ |\\ C_6H_4.C.O\end{array}$

. Mol. w. 258. [235°]. Occurs in American petroleum to which, according to Prunier (*Bl.* [2] 31, 293), it imparts the blue fluorescence. Obtained by oxidising chrysene with CrO_3 in HOAc (Liebermann, *A.* 158, 309; Graebe, *B.* 7, 782; E. Schmidt, *J. pr.* [2] 9, 250, 270). Orange plates (from alcohol); m. sol. benzene and HOAc, sl. sol. ether and CS_2. May be sublimed. Conc. H_2SO_4 forms a deep-blue solution whence it is ppd. unaltered by water. $NaHSO_3$ forms a crystalline compound, decomposed by much water.

Reactions.—1. $KMnO_4$ gives phthalic acid (Anschütz a. Japp, *B.* 11, 211).—2. Distillation over *zinc-dust* forms chrysene.—3. Aqueous SO_2 at 100° forms hydro-chrysoquinone. This body is also formed by the action of zinc-dust and aqueous KOH. It is an amorphous white powder, re-oxidised by air at 200°, or by shaking its solution in H_2SO_4 with air.—4. PCl_5 and $POCl_3$ at 200° form di-chloro-chrysoquinone and deca-chloro-chrysene.—5. Distillation with *soda-lime* gives a hydrocarbon $C_{16}H_{12}$ (? phenyl-naphthalene).—6. Heated with *benzoic aldehyde* and aqueous NH_3 in sealed tubes at 100° it forms a product which, if boiled first with alcohol and then with benzene, yields to the latter a body $C_{25}H_{15}NO$ crystallising in silky needles [259°–265°] which may be sublimed. The reaction is analogous to that of benzoic aldehyde and ammonia on phenanthraquinone (*q.v.*), hence this body should be



(Japp a. Streatfeild, *C. J.* 41, 157).

Di-chloro-chrysoquinone $C_{18}H_8Cl_2O_2$. From chrysene $POCl_3$ and PCl_5 (2 mols.) at 200°; a yellow flocculent pp. is then obtained by adding alcohol (L.).

Di-bromo-chrysoquinone $C_{18}H_8Br_2O_2$. Red leaflets. [160°–165°]. Prepared by bromination of chrysoquinone (Adler, *B.* 12, 1893).

Di-nitro-chrysoquinone $C_{18}H_8(NO_2)_2O_2$. [230°]. From chrysoquinone and HNO_3 (S.G. 1·4) (A.). Red needles.

Tetra-nitro-chrysoquinone $C_{18}H_6(NO_2)_4O_2$. From chrysoquinone and cold conc. HNO_3. Orange powder (L.).

Chrysoquinone di-sulphonic acid $C_{18}H_8(SO_3H)_2O_2$.—BaA″ (A.).

Di-oxy-chrysoquinone $C_{18}H_8(OH)_2O_2$. *Chrysezarin.* [above 300°]. Said to have been extracted from crude artificial alizarin (Claus, *B.* 8, 157). Dark brown needles with bronze lustre (from HOAc). Insol. cold water, sol. alcohol, ether, and alkalis.

CHRYSO-TOLU-AZINE $C_{25}H_{16}N_2$ *i.e.*

$C_{18}H_{10}\langle N|N \rangle C_6H_3(CH_3)$. Prepared by mixing a solution of chrysoquinone in aqueous-alcoholic $NaHSO_3$, with an aqueous solution of tolylene-*o*-diamine hydrochloride, sodium acetate, and acetic acid. Small golden needles. Sublimable. Dissolves in conc. H_2SO_4 with a blackish-violet colour (Liebermann a. Witt, *B.* 20, 2443).

CHRYSOTOLUIDINE $C_{21}H_{21}N_3$ (?). Found among the by-products in the preparation of rosaniline (De Laire, Girard, a. Chapoteaut, *C. R.* 63, 964).

CICUTA OIL. The oil from the seeds of *Cicuta virosa* is of the same nature as Roman oil of chamomile (*q. v.*) (Trapp, *J. pr.* 74, 428).

CICUTENE $C_{10}H_{16}$. (160°). A dextrorotatory terpene in the essential oil obtained from the root of the water-hemlock, *Cicuta virosa* (Ankum, *Z.* 1869, 248). The same plant is said to contain an alkaloid, Cicutine (Polex, *Ar. Ph.* 18, 174; Wittstein, *Buchner's Repert.* 18, 19).

CIMICIC ACID $C_{15}H_{28}O_2$. Mol. w. 240. [44°].

Occurrence.—In the fœtid oil ejected by a kind of bug *Rhaphigaster punctipennis* when irritated. The insects are washed with alcohol, and the residue extracted with ether (Carius, *A.* 114, 147). Occurs also in spider's web (Valente, *G.* 12, 557).

Properties.—Prisms (from ether), lighter than water. Insol. water, v. sl. sol. alcohol, v. sol. ether. Has a rancid odour.

Salts.—NaA′.—KA′: amorphous.

Chloride $C_{15}H_{27}OCl$: [c. 44°].

Ethyl ether EtA′. Oil.

CIMICIC ALDEHYDE $C_{15}H_{28}O$. [72°]. Occurs in spider's web (Valente, *G.* 12, 557). Reduces Fehling's solution and ammoniacal $AgNO_3$.

CINCHAMIDINE *v.* CINCHONA BASES.

CINCHENE $C_{19}H_{20}N_2$. *Cinchonidene.* [125°]. Formed by treatment of cinchonine or cinchonidine with PCl_5, and boiling the resulting cinchonine-chloride $C_{19}H_{21}Cl$ or cinchonidine chloride with alcoholic KOH. Trimetric tables $a:b:c = ·6017:1:·5022$. By heating with HCl at 220°–230° it is converted into apocinchene $C_{18}H_{17}NO$, MeCl and NH_3 being split off and H_2O taken up (Comstock a. Königs, *B.* 14, 1854; 17, 1989).

Methylo-iodide B′MeI: [186°]; monosymmetrical tables, $a:b:c = 1·5838:1:·9114$; v. sol. alcohol, sl. sol. water, scarcely sol. ether (Comstock a. Kœnigs, *B.* 18, 1219).

(α)-Cinchene-di-bromide $C_{19}H_{20}Br_2N_2$. [113°]. Formed, together with about an equal quantity of (β)-cinchene-di-bromide, by the addition of bromine to cinchene (Comstock a. Königs, *B.* 19, 2858; 20, 2512). Monosymmetrical crystals, $a:b:c = ·9570:1:·8686$, $\beta = 65° 52'$. Converted by boiling with alcoholic KOH into dehydrocinchene. The hydrobromide forms concentric needles; the nitrate small colourless crystals, sl. sol. dilute HNO_3; the zinc-double chloride colourless needles [c. 250°].

(β)-Cinchene-di-bromide $C_{19}H_{20}N_2Br_2$ [134°]. Formed, together with (α)-cinchene-di-bromide [113°], and in about equal quantity, by the addition of bromine to cinchene. Rhombic sphenoidal hemihedral crystals, $a:b:c = ·5552:1:1·2017$. Somewhat less sol. alcohol and ether than the (α)-isomeride. Like the (α)-isomeride it is converted by boiling with alcoholic KOH into dehydrocinchene. The hydrobromide forms granular crystals more soluble than the (α)-hydrobromide (*separation*). The zinc-double chloride forms colourless needles [c. 250°]. The nitrate separates in the form of a jelly, sl. sol. dilute HNO_3 (C. a. K.).

Cinchene-bromo-hydride $C_{19}H_{21}BrN_2$. *Hydrobromcinchene.* [105°–116°]. Formed by dissolving cinchene in cooled HBr and allowing to stand for two days. Monoclinic crystals, $a:b:c = ·8541:1:·8280$, $\beta = 63° 7'$; isomorphous with cinchene-di-bromide. V. sol. alcohol, ether, benzene, chloroform, and acetic ether, sl. sol. ligroïn (Comstock a. Königs, *B.* 20, 2522).

Dehydrocinchene $C_{19}H_{18}N_2$. [c. 60° hydr.]. Obtained by boiling dehydrocinchonine chloride, $C_{19}H_{19}N_2Cl$ or (α)- or (β)-cinchene-di-bromide $C_{19}H_{20}Br_2N_2$ with alcoholic KOH. Long colourless needles (with 3aq).—$B''H_2Br_2$: very soluble small prisms.—$B''H_2Cl_2PtCl_4$: very sparingly soluble red tables (Comstock a. Königs, *B.* 19, 2857).

Apocinchene $C_{19}H_{19}NO$. [209°]. Formed by heating cinchene with HCl at 220°–230° (Comstock a. Königs, *B.* 14, 1854; 17, 1986; 18, 2379; 20, 2674). Colourless needles. Sol. alcohol, acids, and alkalis. The compounds which it forms with acids and with bases are dissociated by water.

Reactions.—By fusion with KOH or NaOH it gives oxy-apocinchene $C_{18}H_{17}NO_2$. Its ethers are oxidised by CrO_3 to cinchonic acid; on oxidation with dilute HNO_3 they yield alkyl-apocinchenic acids $C_{17}H_{12}(OR)N.CO_2H$.

Salts.—B′HBr. [c. 256°]: yellow needles (from alcoholic HBr).—B′HI.—$B'_2H_2PtCl_6$. [c. 235°]. The Ag salt is a nearly insoluble pp.

Acetyl derivative $C_{19}H_{18}AcNO$. [119°].

Methyl ether $C_{19}H_{18}(OMe)N$: oil; v. sol. alcohol, ether, &c., nearly insol. water. B′HCl $\frac{1}{2}$aq: [c. 198°], crystalline solid.

Ethyl ether $C_{19}H_{18}(OEt)N$: [71°]; colourless prisms.

Bromo-apocinchene $C_{19}H_{18}BrNO$. [188°]. From apocinchene hydrobromide in chloroform and HOAc by adding Br. Crystalline, v. sol. aqueous alkalis, benzene, and chloroform, less sol. alcohol and ether. CrO_3 oxidises it to bromoform and cinchonic acid. Boiling alcoholic NaOH does not attack it.

Di-bromo-apocinchene. *Ethyl ether* $C_{19}H_{16}Br_2(OEt)N$. [118°]. From ethyl-apocinchene (10 g.) and Br (15 c.c.)

Oxy-apocinchene $C_{19}H_{19}NO_2$. [317°]. Formed by fusing apocinchene $C_{19}H_{18}(OH)N$ with KOH or NaOH (Comstock a. Kœnigs, *B.* 18, 2385). Colourless crystals. V. sol. caustic alkalis, sl. sol. cold alcohol and pure ether, nearly insol. water and dilute acids.

Acetyl derivative $C_{19}H_{18}AcNO_2$. [203°].

Methyl-apocinchenic acid $C_{17}H_{13}(OMe)N.CO_2H$. [234°]. Formed by oxidation of the methyl ether of apocinchene with dilute HNO_3 (Comstock a. Kœnigs, *B.* 18, 2383). Colourless crystals. V. sol. alcohol, acids and alkalis, nearly insol. water.

Ethyl-apocinchenic acid $C_{17}H_{13}(OEt)N.CO_2H$. Formed by oxidation of the ethyl ether of apocinchene $C_{19}H_{18}(OEt)N$ with dilute HNO_3 (Comstock a. Kœnigs, *B.* 18, 2384; 20, 2674). Crystallises from absolute alcohol in yellowish anhydrous needles [162°]; from dilute alcohol in crystals (containing aq) [126°]. By heating with HCl at 130° it is split up into CO_2, EtCl, and homo-apocinchene $C_{17}H_{15}NOxaq$ [185°]. The hydrobromide of homoapocinchene B'HBraq crystallises in yellow needles or prisms [222°] sl. sol. water. Homo-apocinchene on fusion with potash gives an acid [230°] split up by heat into CO_2 and another acid $C_{17}H\,NO_2$ (?) [223°].

Salts.—The Ag, Ca, Ba, Pb, Zn, and Cu salts are sparingly soluble.—AgA'.—$(HA')_2H_2PtCl_6$.

CINCHOL $C_{20}H_{34}O$. [139° water-free]. Is found in all true cinchona barks but not in *C. Cuprea*; in largest amount (up to 0·03 p.c.), along with some quebrachol, in *C. Calisaya Var. Ledgeriana*. Found also along with cupreol. Helms' 'Cinchocerotine' (*Ar. Ph.* [3] 21, 279) was probably wholly or partly cinchol. Further, Liebermann's 'Oxy-chino-terpene' (*B.* 17, 871) is cinchol (Hesse).

Preparation.—From crude cupreol, the acetate being separated by repeated crystallisations from alcohol from the acetates of quebrachol and cupreol (O. Hesse, *A.* 228, 288; 234, 375).

Properties. Plates (containing aq) from alcohol. Lævorotatory in chloroform solution; $[\alpha]_D = -34{\cdot}3°$ (in a 6 p.c. solution). Its properties are similar to those of cupreol.

Acetyl derivative $C_{20}H_{33}O(C_2H_3O)$. [124°]. White needles from alcohol. M. sol. alcohol, v. sol. ether and chloroform. Lævorotatory (in chloroform); $[\alpha]_D = -41{\cdot}7°$ (in a 4 p.c. solution).

Propionyl derivative $C_{20}H_{33}O(C_3H_5O)$. [110°]. Microscopic plates.

CINCHOCEROTIN $C_{27}H_{48}O_2$. [130°]. Probably identical with the preceding. Deposited in tubes through which an alcoholic extract of South American calisaya bark and lime is passed (Helms, *Ar. Ph.* [3] 21, 279). Chromic acid gives acetic acid, butyric acid, and cinchocerotic acid $C_{10}H_{22}O_2$ [72°].

CINCHOLEPIDINE *v.* (*Py.* 1) METHYL-QUINOLINE.

CINCHOLINE. Strongly basic oil. Volatile with steam. Occurs in the mother liquors from quinine. V. sol. alcohol and ether, less sol. water. The **hydrochloride** forms colourless quadratic plates. The **oxalate** is sparingly soluble in water (Hesse, *B.* 15, 858).

CINCHOMERONIC ACID and **iso-cinchomeronic acid** *v.* PYRIDINE DI-CARBOXYLIC ACID.

CINCHONA BARK. *Cortex Cinchonæ* and *Chinæ*, *Cortex Peruvianus*, *Peruvian Bark*, *Ecorce de Quinquina*, *China rinde*.—This name is given to the bark of various species of *Cinchona*, which, with about thirty other allied genera, constitute the tribe *Cinchoneæ* of the order *Rubiaceæ* (*v. Pharmacographia*, f. 338). They have been long known for their antifebrile properties, which are chiefly due to the contained alkaloids, which are absent in all the allied genera, with the exception of *Remigia*, some species of which contain them.

These medicinal barks were first introduced into Europe from Peru about the year 1638, by the Countess of Chinchon, wife of the Viceroy of Peru (in whose honour the name cinchona was given to the genus by Linnæus), and being afterwards sent over by the Jesuits, acquired great celebrity for the cure of intermittent fevers, being known by the names of Pulvis Comitessæ, Jesuiticus, Patrum, &c. The cinchonas are natives of the mountain regions of South America, on the eastern slope of the Cordillera of the Andes and on the mountain ranges of Ecuador and New Granada, growing at elevations from 3,000 to 11,000 feet, no species being known to inhabit the low alluvial plains.

In 1853 an attempt was made by the Dutch Government to introduce the cultivation of cinchona into Java, but at first great difficulty was found in obtaining seeds or plants of good qualities, owing to the extreme jealousy of the natives.

In 1860 Mr. Clements Markham was sent by the Government of India to South America to collect seeds and plants, and after great difficulties he and his coadjutors succeeded in introducing the most valuable species of cinchona into India, and Mr. C. Ledger, who was then residing on the west coast of America, also succeeded in obtaining a supply of seed of the finest variety of the Calisaya bark.

The cultivation of the cinchonas thus introduced into the East Indies has increased to such an extent that much the greater proportion of the bark is now supplied from Ceylon, Java, and India, from whence upwards of 14,000,000 lbs. of bark were imported in 1885.

This cultivation has also been successfully introduced into Jamaica and elsewhere, in tropical regions where high mountains give the requisite elevation, and in the natural home of the genus there are now large plantations of cultivated cinchonas of the finest qualities.

In collecting the bark in the native forests, the trees are invariably cut down, and the bark, when stripped off, dried either in the sun or on hurdles arranged over a fire in a hut.

In the plantations of cultivated bark, the system of cutting down the trees is adopted to some extent, but a far more economical method of harvesting the bark is by the process of 'renewing,' introduced by the late W. G. McIvor, by which a succession of crops of bark can be obtained from the same tree. For this purpose longitudinal incisions are made into the bark and about half the bark removed in alternate strips, leaving the remaining bark intact, and the stem is then covered with moss. A fresh layer of bark is then formed from the cambium with surprising rapidity, and in a few months it attains the thickness of the original bark when several years old.

It is remarkable that the renewed bark is not only in most cases richer in total alkaloids than the natural bark but contains a far higher proportion of quinine, which appears to take the place of the less valuable alkaloids. Another more imperfect process adopted for renewing barks is to cut off the external layers with a spokeshave, but the results are rarely so good as in the former process, as it is essential that the liber layers of the bark should be cut through without injuring the cambium beneath, which is more difficult to do in this manner than in the other system.

Between thirty and forty species of cinchona have been described, but most of them are of no practical value. Those used in pharmacy and in the manufacture of quinine are as follows.

I. *Yellow or Calisaya Bark.* This is the most valuable of all the species of cinchona. It is found in commerce in quills formed by the contraction of the bark when drying, which are covered with a rough epidermis. It was formerly found also in flattened pieces, from which the epidermis had been removed, and which have been dried under pressure, and was then known as flat yellow bark.

II. *Crown bark. Pale bark. Loxa bark* yielded by *C. officinalis* and the allied species, found in quills, with a rough blackish-brown or dark grey surface. This was formerly the chief bark used in medicine under the name of Peruvian bark. It is largely cultivated and approaches the Calisaya in richness.

III. *Red bark, Cinchona Rubra and Succirubra,* so called from the red colour of the sap and of the mature bark. Owing to the vigorous growth of this species, it has been cultivated in India to a very large extent, and has been adopted in the British Pharmacopœia for use in galenical preparation. It is less suited for the preparation of quinine, owing to the great proportion of cinchonidine that it contains.

IV. *Soft bark. Columbian and Carthagena bark,* yielded by *C. Lucumæfolia and Lancifolia,* imported in quills or broken pieces, with a whitish shining epidermis, which scales off easily. They vary greatly in the quantity and quality of the alkaloids.

V. *Pitayo barks,* yielded by *C. Pitayensis,* are imported in short curly pieces of a brownish colour, either bare or with a rugged whitish epidermis. They are rich in alkaloids, especially quinine and quinidine.

VI. *Cuprea bark,* yielded by *Remigia Pedunculata.* Although not a true cinchona bark, this may conveniently be included here as the only known species of any other genus that has yielded the cinchona alkaloids. It is imported in short quills and broken pieces of a deep red colour. The bark is of a very compact texture, of much higher specific gravity than the true cinchonas. It gives with ammonia a purple solution of considerable tinctorial power. It contains quinine, quinidine, cinchonine, but no cinchonidine, and an alkaloid, cupreine, discovered by Paul and Cownley, which exists in the bark in a combination with quinine, previously taken for a distinct alkaloid, and designated homoquinine, an allied species. *R. Purdieana* yields no quinine, but a new alkaloid called by the discoverer, M. Arnaud, Cinchonamine.

Along with these principal species are found in commerce the bark of a great number of species of *Cinchona,* most of which contain little or no valuable alkaloid, and also barks of allied genera, especially of *Ladenbergia* and *Exostemma.* These barks contain none of the cinchona alkaloids.

The organic constituents of cinchona bark are quinine, quinidine, cinchonine and cinchonidine, and some isomeric modifications of these bases, quinamine, uncrystallisable alkaloids, in some species aricine, paricine, and their congeners; quinic acid, quinovin and cinchotannic acid, cinchona red, colouring matter, wax, and fatty matter, a small quantity of volatile oil, along with starch, gum, and woody fibre.

The barks of some of the allied genera also contain quinovin, cinchotannic acid, and quinic acid. The ash of cinchona bark consists chiefly of calcic and potassic carbonate, containing also, besides iron, a notable quantity of manganese. For detailed analysis vide Carles, *Ph.* [3] 3, 723.

The first chemical examination of cinchona bark appears to have been made in 1785 by Hermbstädt, who obtained from it calcium quinate, which he designated as essential salt of quinine. Schneider in 1807, and Vauquelin in 1808, separated quinic acid from the calcium salt. Quinotannic acid was discovered by Deyeux in 1793, and obtained in a more definite form by Séguin in 1797. Cinchona bitter and cinchona red were obtained from red cinchona bark by Reuss in 1810. The first discovery of the alkaloids was made by Gomes of Lisbon in 1811, who appears to have obtained cinchonine in an impure state; but its true nature was not discovered till 1820, when Houton-Labillardière drew attention to its alkaline reaction, and communicated his observations to Pelletier and Caventou, who in the same year succeeded in isolating first cinchonine, and afterwards quinine, and proved them to be true vegetable alkaloids. The isomeric modifications of these alkaloids were afterwards discovered and variously named. Pasteur (*C. R.* 36, 26; 37, 110) reduced those then known to four, quinine and its isomeride, quinidine, and cinchonine and its isomeride, cinchonidine, and also investigated the isomeric modifications of these alkaloids produced by the action of heat in strong acid solution, viz. quinicine and cinchonicine. Hesse has now investigated the whole subject, and has described various alkaloids which, however, with the exception of a modification of cinchonidine named by him 'homo-cinchonidine,' and the recently discovered hydroquinine, do not seem to have been isolated by other observers.

Cinchona barks are employed medicinally in the form of tinctures, fluid extracts, and infusions, and were thus used long before the discovery of the alkaloids, and, although it is to these bodies that the medicinal value is chiefly due, the cinchotannic acid and other ingredients appear also to be of medicinal value.

Reactions of Cinchona bark.—Most salts of the cinchona alkaloids give a purple tar when strongly heated in a test-tube, especially if they are mixed with cellulose. The same reaction is observed when a bark containing them is heated, and is very characteristic. The test was proposed by Grahe, of Kasau, in 1858. Water extracts a portion only of the alkaloidal contents of cinchona bark, and the cinchotannates of the alkaloids being more soluble in hot than in cold water, a hot infusion becomes turbid on cooling. The solution obtained by treatment with acidulated water gives the following reactions:—The alkaloids give a whitish precipitate with excess of caustic alkali, and with tannic acid, and a yellow crystalline precipitate with platinic chloride, if these precipitates are submitted to dry distillation, the characteristic odour of quinoline is observed. Of the acid constituents quinotannic acid gives precipitates white with solution of gelatin, green with ferric salts, dirty white with tartar emetic. Quinovic acid gives, with sulphate of copper, first a green colour and then a precipitate which, when washed, has a bitter metallic taste. Quinic acid distilled with sulphuric acid and manganese peroxide yields a distillate of quinone; this test is proposed by Stenhouse (*Mem. Chem. Soc.* ii. 226) to distinguish true cinchona bark.

For the **quantitative analysis** of cinchona bark, various processes have been proposed, many of which give good results in practised hands, but in all of which success largely depends on details of manipulation only to be acquired by practice. The earlier processes depended on dissolving out the alkaloids with hydrochloric acid, precipitating the alkaloids by caustic alkali. A great excess of acid is required for the extraction of the whole alkaloid, and a great excess of alkali for the complete separation of the alkaloids from the cinchotannic acid which precipitates along with them by exact neutralisation. Better methods are those in which the salts of the alkaloids are decomposed in the bark by treatment with alkali, and the alkaloids then extracted by suitable solvents. De Vrij (*Pharmacographia*, p. 365, and *Ph.* [3] 4, 241) recommends to mix 20 g. of powdered bark with milk of lime (5 g. lime to 50 c.c. water), dry the mixture slowly, stirring frequently. Then boil the dry powder with 200 c.c. alcohol of S.G. 0·830, pour off and filter the solution, and boil again with 100 c.c. alcohol, throw the whole on the filter, and wash further with 100 c.c. alcohol, acidulate with dilute sulphuric acid, filter, and distil, but not to dryness (water must be added if necessary), when all the spirit is separated the aqueous solution is filtered. The filtrate and washings are reduced to 50 c.c., and while still warm treated with caustic soda in excess. After cooling, the solution is decanted off and water added before throwing it on the filter. It is then washed with the smallest possible quantity of water, pressed between folds of blotting paper, dried, and weighed. The weight is that of the total alkaloids in the bark.

The process given in the *British Pharmacopœia*, f. 111, is also a good one, it is as follows:—Mix 200 grams of the bark in fine powder with 60 grams of hydrate of calcium; moisten the powders with half an ounce of water, mix the whole intimately; allow it to stand for an hour or two, it will then present the characters of a moist dark-brown powder, in which there should be no lumps or visible white particles. Transfer the powder to a flask, boil for half an hour with three fluid ounces of a mixture of three volumes of benzene and one of amylic alcohol, decant and filter the solution, leaving the bark in the flask, boil again with the same solvent and decant as before; repeat the third time, and finally throw the bark on the filter and wash with the solvent. The filtrates are then shaken repeatedly with water acidulated with hydrochloric acid till the alkaloids are all removed, the acid washings concentrated, and if the process given below for the separation of the alkaloids is adopted, the alkaloids are precipitated by excess of alkali.

The process given in the German *Pharmacopœia* is also efficient.

The separation of the cinchona alkaloids depends on their relative solubilities in various reagents, but in most cases these do not differ so widely as to give a perfectly satisfactory separation, and the separation is made more difficult by the tendency of the alkaloids and their salts to form more or less definite compounds with one another.

A convenient process giving fairly accurate results is as follows:—Treat the powdered mass of mixed alkaloids with ten times its weight of ether; this will dissolve the quinine and amorphous alkaloid, and small quantities only of the other alkaloids; wash the alkaloids out of this ethereal solution by excess of dilute sulphuric acid, and neutralise after heating to boiling with dilute ammonia, using no more water than is necessary; the quinine will then, on cooling, crystallise out almost entirely as sulphate, which salt is almost insoluble in a cold solution containing ammonic sulphate. The crystals after filtration and washing with a small quantity of water are pressed between blotting paper and dried at 100°. 73·4 pts. of the anhydrous salt equal 100 of the hydrated crystals. The salt should be tested for cinchonidine, which may be present in small quantity. The alkaloids contained in the mother liquor are then precipitated by alkalis, converted into neutral acetates, and a solution of potassium iodide and a small quantity of alcohol is then added; on standing quinidine iodide will crystallise out if present. Of this salt 100 pts. equal 71·8 of the alkaloid. A solution of potassio-tartrate of sodium is then added to the mother liquor, and on agitation and standing, tartrate of cinchonidine will crystallise out if any of that alkaloid has been dissolved by the ether; 100 pts. of this salt equal 80·4 of the alkaloid. The mother liquor now contains amorphous alkali, which may be precipitated by a solution of sodic hydrate and weighed. The portion insoluble in ether must be also converted into neutral acetates, and the solution tested for quinidine by potassic iodide, a few drops of spirit being added, and for cinchonidine by potassio-tartrate of sodium as above. If a considerable proportion of this alkaloid is present it will probably contain a notable quantity of quinine, as ether fails to give a complete separation. After removal of any quinidine and cinchonidine present by those reagents, the solution contains the cinchonine, which may be precipitated by caustic alkali and weighed. Dr. de Vrij recommends that the quinine should be precipitated from the solution of alkaloids soluble in ether, as iodo-sulphate (*Ph.* [3] 6, 461); in skilful hands this method of analysis gives accurate results. Instead of commencing the separation of the alkaloids by ether, Dr. Moens recommends that the neutral aqueous solution of the mixed alkaloids be treated with excess of solution of sodic potassio-tartrate, which throws down the whole of the quinine and cinchonidine as tartrates. The tartrate is then decomposed by alkali, and the quinine and cinchonidine separated by ether, the alkaloid dissolved in the ether being either weighed directly as quinine or preferably converted into sulphate and weighed as such. Great care must be taken in this case to decompose the tartrate entirely, to avoid underestimating the quinine.

The method of estimating the relative proportions of quinine and cinchonidine in the precipitated tartrates by determination of the specific rotation of the polarised ray has been recommended by Drs. De Vrij and Oudemans, but no published process for bark analysis gives the tartrate obtained direct from the crude mixed alkaloids in a sufficient state of purity to give really trustworthy results by this method.

The distribution of the alkaloids in the bark has been the subject of careful observation. It was first observed by Carles (*Ph.* [3] 3, 643) that though quinine exists in all portions of the bark, it is contained in much larger proportion in the external and cortical layers than in the internal liber layers, and his observation has been confirmed by other observers.

On the other hand, the corky epidermis found in some barks, specially in certain varieties of officinalis, such as the knotty bark of Jussieu does not contain alkaloid.

Alkaloids begin to form in the bark even when very young, and increase in quantity until the bark is mature, the maximum yield being attained at ages varying with the species and circumstances of growth—from five to fifteen years, or even later. The relative proportion of the different alkaloids also varies greatly in the same tree.

The increase of the dextrogyrate alkaloids, quinidine and cinchonine, in the root barks is remarkable. This is specially the case in stunted or unhealthy trees in which the root bark is often exceptionally rich in alkaloid. As a rule a luxuriant growth of the plant is required to give the maximum of alkaloid, and therefore it is natural that manures should have a beneficial effect. Valuable experiments on this subject have been carried out by Mr. Broughton at the Government Plantation at Ootacamund (*Ph.* [3] 3, 521). He found that a great improvement in the yield of quinine was caused by the use of guano, a greater by the use of ammonia salts, but most of all by the use of farmyard manure. A series of experiments on renewed bark of *C. succirubra* in Ceylon, on the other hand, showed a maximum of improvement from the use of bones; ammonia and cattle manure producing less improvement, the different result being, no doubt, owing to a different condition of the soil. In some soils a very great improvement is caused by dressings of lime. This question is one deserving of much more investigation than it has yet received. D. H.

CINCHONA BASES.—Quinine, Cinchonine, Cinchonidine, and Aricine are described in separate articles. The existence of many of the following bases requires confirmation. In the names of these alkaloids *qu* is used before *i*, and *ch* before any other vowel.

Chairamine $C_{22}H_{26}N_2O_4$ aq. [140°]. [233° when dry] $[\alpha]_D$ = about + 100°. In the bark of *Remijia Purdieana* (Hesse, *A.* 225, 243). Named from χαίρω, because Hesse 'rejoiced' at discovering it. Slender needles (containing aq) (from dilute alcohol). Sol. ether and chloroform. Its alcoholic solution is alkaline to litmus. H_2SO_4, with or without MoO_3, forms a colourless solution, turning dark green.

Salts.—B′HCl aq. Needles.—$B'_2H_2SO_4$ 8aq. —$(B'HCl)_2PtCl_4$ 2aq.

Conchairamine $C_{22}H_{26}N_2O_4$aqEtOH. [82°-86°]; B′aq [c. 110°]; B′ [c. 120°] $[\alpha]_D$ (for B′) = +68·4 in 2 p.c. alcoholic solution. In the bark of *Remijia Purdieana* (Hesse, *A.* 225, 246). It has three melting-points according as it is dry, with water of crystallisation, or with alcohol of crystallisation also. Colourless prisms (containing aqEtOH) (from alcohol). Sol. ether and chloroform. Conc. H_2SO_4, with or without MoO_3, forms a brown solution turning green.

Salts. — B′HCl. — $(B'HCl)_2PtCl_4$ 5aq. — B′HI aq.—B′HSNC aq.—$B'_2H_2SO_4$ 9aq.

Methylo-iodide.—B′MeI aq. Red crystals. B′MeI 3aq. Colourless crystals.

Methylo-chloride.—B′MeCl 2aq. Platino-chloride.—$(B'MeCl)_3HCl(PtCl_4)_2$ 14aq.

Chairamidine $C_{22}H_{26}N_2O_4$ aq. [c. 128° when dry]. $[\alpha]_D = +7{\cdot}3°$ in 3 p.c. alcoholic solution. In the bark of *Remijia Purdieana* (Hesse, *A.* 225, 253). Amorphous powder, insol. water, sol. ether, alcohol, benzene, and chloroform; solution in conc. H_2SO_4 slowly turns green. Animal charcoal removes it from solution in acetic acid.

Salts.—$(B'HCl)_2PtCl_4$ 5aq.—Sulphate is gelatinous.

Conchairamidine $C_{20}H_{26}N_2O_4$ aq. [115° when dry]. $[\alpha]_D = -60°$ in a 3 p.c. alcoholic solution. In the bark of *Remijia Purdieana* (O. Hesse, *A.* 225, 256). Crystalline. V. sol. ether, alcohol, chloroform, benzene, and acetone. Its alcoholic solution is neutral to litmus. In conc. H_2SO_4, with or without MoO_3, the solution is dark green.

Salts. — Well crystallised. — B′HCl 3aq. — $(B'HCl)_2PtCl_4$ 5aq.—$B'_2H_2SO_4$ 14aq.

Cinchamidine $C_{20}H_{26}N_2O$. [230°]. $[\alpha]^D = -98{\cdot}4$. Occurs in the mother-liquors from homocinchonidine (Hesse, *B.* 14, 1683; *cf.* Forst a. Böhringer, *B.* 14, 1270; 15, 520). Colourless plates, needles, or prisms. Sol. alcohol and chloroform, sl. sol. ether, insol. water. Has an alkaline reaction.

Salts. — B′HCl 2aq: trimetric prisms. — $(B'HCl)_2PtCl_4$ 3aq: yellow amorphous pp. — $B'H_2Cl_2PtCl_4$: orange plates. — Tartrate $B'_2C_4H_6O_6$ 2aq: colourless prisms, sl. sol. cold water.

Cinchonamine $C_{19}H_{24}N_2O$. [194°] (A.); [185°] (H.). $[\alpha]_D = +121°$ (1 pt. base in 50 pts. of 97 p.c. alcohol at 15°).

Occurrence.—In *Cinchona Purdieana* (Arnaud, *C. R.* 93, 593; 97, 174; Hesse, *A.* 225, 218; Planchon, *J. Ph.* [5] 5, 352).

Properties.—Colourless hexagonal prisms (Friedel, *C. R.* 105, 985). Sol. alcohol, ether, chloroform, CS_2 and benzene; sl. sol. petroleum or water. Highly poisonous. Its alcoholic solution is alkaline and gives no colour with Fe_2Cl_6 or Cl and NH_3. In conc. H_2SO_4 forms reddish-yellow solution, in conc. HNO_3 a bright yellow solution. In HCl it is insoluble, and on heating at 150° it gives no MeCl.

Salts.—B'HCl.—B'HCl aq.—$(B'HCl)_2PtCl_4$.—B'HBr.—B'HI.—B'HSCN.—$B'HNO_3$. S. ·2 at 15°.—$B'_2H_2SO_4$. $[\alpha]_D = +36{\cdot}7°$ at 15° in 2 p.c. solution (H.); ,, = +43·5 at 15° (A.). V. sol. water. $B'H_2SO_4$ $[\alpha]_D = 34{\cdot}6°$.—$B'H_2S_2O_3$.—Tartrate $B'_2H_6C_4O_6$. S. 1·15 at 15°.—Malate $B'C_4H_6O_5aq$: S. 1 at 15°.—Citrate: prisms. S. 1·95 at 16°.

Acetyl derivative $C_{19}H_{23}AcN_2O$. [80°–90°]. Amorphous. Sol. acetic acid, ether, alcohol, and chloroform, sparingly so in dilute HCl. In conc. H_2SO_4 it forms a purple solution, turned yellow by heat. Not saponified by alcoholic potash.

Di-nitro-cinchonamine $C_{19}H_{22}(NO_2)_2N_2O$. [118°]. Formed by treatment with HNO_3 of S.G. 1·06. Explosive. Flocculent pp., sol. acetic acid, ether, chloroform, and alcohol, and in dilute HCl.—$(C_{19}H_{22}(NO_2)_2N_2OHCl)_2PtCl_4$.

Methylo-iodide B'MeIaq.

Methylochloride B'MeCl.—$(B'MeCl)_2PtCl_4$. The hydrate B'MeOH gives methyl-cinchonamine on boiling with water.

Methyl-cinchonamine $C_{19}H_{23}MeN_2O$. [139°]. Amorphous powder, v. sol. alcohol, ether, and chloroform, insol. water. Sulphomolybdic acid is slowly turned dark blue by it. Forms a flocculent platino-chloride $(C_{19}H_{23}MeN_2OHCl)_2PtCl_4$ 4aq.

Ethylo-iodide B'EtI. Insol. water. When treated with AgCl and $PtCl_4$ successively it gives $(B'EtCl)_2PtCl_4$ 2aq. And with Ag_2SO_4 it gives $(B'Et)_2SO_4$. When an alcoholic solution of B'EtI is boiled with addition of a little NaOH, ethyl-cinchonamine is formed.

Ethyl-cinchonamine $C_{19}H_{23}EtN_2O$,aq. [75°–78°]; when dry it melts at [c. 140°]. Amorphous, resembling methyl-cinchonamine. Platino-chloride: $(C_{19}H_{23}EtN_2OHCl)_2PtCl_4$ 3aq.

Cincholine. An oily alkaloid which accompanies quinine (Hesse, *B.* 15, 858).

Hydrocinchonidine $C_{19}H_{24}N_2O$. [229°–230°] $[\alpha]_D = 98{\cdot}4$ (in 97 p.c. alcohol, $p = 2$) (Forst a. Böhringer, *B.* 14, 1270; 15, 520; O. Hesse, *B.* 14, 1893; *A.* 214, 1). Found in the mother-liquors from which cinchonidine sulphate or homo-cinchonidine sulphate has crystallised. Six-sided plates (from hot dilute alcohol) or short prisms (from strong alcohol). Less sol. alcohol than cinchonidine or homo-cinchonidine. V. sl. sol. chloroform, ether, or water. Freshly ppd. sl. sol. ether, quickly separating again in six-sided plates. Alcoholic solution is alkaline and bitter.

Reactions.—1. Its sulphate does not at once bleach $KMnO_4$ and shows no fluorescence.—2. *Ammonia* gives, in solutions of its salts, a flocculent pp. becoming crystalline; in very dilute solutions a crystalline pp. after some time.—3. *Chlorine* and NH_3 give no colour.—4. Conc. H_2SO_4 dissolves it without colour.—5. Insoluble in KOH, baryta or lime.—6. HCl (S.G. 1·125) at 160° has no action.

Salts.—(Hesse.) B'HCl 2aq.—B'CNSH.—$B'_2H_2PtCl_6$ 3aq.—$B'H_2PtCl_6$.—$B'C_7H_{12}O_6$ (quinate).—$B'_2H_2C_2O_4$.—$B'_2C_4H_6O_6$ (tartrate).—$B'_2H_2S_2O_3$ aq.—$B'H_2SO_4$ 4aq.—$B'_2H_2SO_4$ 7aq. S. 1·75 at 10°. $[\alpha]_D = -75{\cdot}2°$ (in water, $p = 2$); $-93{\cdot}8°$ (in 97 p.c. alcohol).—$B'_2C_6H_4(OH)SO_3H$ 5aq.

Acetyl derivative $C_{19}H_{23}AcN_2O$. [42°]. $[\alpha]_D = -29{\cdot}5°$ (in 97 p.c. alcohol, $p = 2$); $-50{\cdot}9°$ (in water with 3HCl, $p = 2$). Amorphous hygroscopic mass. V. sol. alcohol. Saponified by alcoholic KOH. Soluble in acids forming salts, *e.g.* $C_{19}H_{23}AcN_2OH_2PtCl_6$ 2aq.

Amorphous hydrocinchonidine $[\alpha]_D = -12°$ (in water with 3HCl, $p = 2$). Is formed by fusing the sulphate at 140°, and adding aqueous NaOH to the product. It is a brownish amorphous base, isomeric with hydrocinchonidine. It is v. sol. ether, alcohol, chloroform, or acids. Its salts are amorphous, *e.g.* $B'H_2PtCl_6$ 2aq.

Di-cinchonine $C_{38}H_{44}N_4O_2$. [40°]. $[\alpha]_D = +66°$. Occurs in the bark of *Cinchona rosulenta* and of *C. succirubra* especially. Not present in the bark of *C. Calisaya, var. Boliviana*, and *var. Ledgeriana, C. Tucujensis* or *C. Pelletierana*, or of *Remijia pedunculata* or *R. Purdicana* (O. Hesse, *A.* 227, 153).

Properties.—Yellowish amorphous base. V. sol. ether, acetone, alcohol, chloroform, and benzene, less sol. water and light petroleum, insol. in aqueous NaOH. Its alcoholic solution is strongly alkaline and tastes bitter, gives no colour with Cl and NH_3, and is dextrorotatory.

Salts.—The base dissolves in dilute acids and is reppd. by NH_3 or NaOH as a resinous pp.—B''2HCl.—$B''2HCl.PtCl_4$.

Reaction.—HCl at 150° converts it into di-apocinchonine, which is also formed from cinchonine under similar conditions.

Hydrocinchonine $C_{19}H_{24}N_2O$. [256°]. Occurs in *C. cuprea* (Hesse, *B.* 15, 855).—$B''H_2PtCl_6$ 2aq.

Cinchotine $C_{19}H_{24}N_2O$. [277° cor.]. S. ·07 at 20°; S. (ether) ·19 at 20°. Occurs in crude cinchonine sulphate (Willm a. Caventou, *A. Suppl.* 7, 218; Forst a. Bohringer, *B.* 14, 436; 1267; 15, 519; Skraup, *A.* 197, 352; *C. C.* 1877, 629). Slender prisms and scales. Dextrorotatory. On oxidation it gives cinchonic acid.

Salts.—$B'_2H_2SO_4$ 12aq: fine needles or prisms. S. 3·28 at 13°.—$B'HNO_3$ aq: tables.—B'HCl 2aq: fine needles.—$B'H_2Cl_2$.—B'HCl 2aq: S. 2·12 at 0°.—B'HBr 2aq.—$B'H_2Br_2$: prisms.—B'HI aq.—Sulphocyanide B'CNSH: long needles, sl. sol. water.—Oxalate $B'_2H_2C_2O_4$ aq: needles; S. 1·16 at 10°.—Tartrates $B'C_4H_6O_6$ 4aq: needles, sol. hot water.—$B'_2C_4H_6O_6$ 2aq: prisms.—Benzoate $B'C_7H_6O_2$: needles, sl. sol. cold water.

Quinamine $C_{19}H_{24}N_2O_2$. [172°]. $[\alpha]_D = 93{\cdot}5°$ (in a 2 p.c. chloroform solution), $[\alpha]_D = 104{\cdot}5°$ (in a 2 p.c. alcoholic solution). S. ·064 at 16°. S. (ether) 2 at 16°. Occurs in the bark of *Cinchona succirubra*, and of many other species of cinchona (Hesse, *A.* 166, 266; 182, 163; 199, 335; 207, 288; De Vrij, *Ph.* [3] 4, 609; *J.* 1874, 874). Obtained from the mother-liquor after quinine and cinchonine have been ppd. as tartrates. Long prisms (from dilute alcohol). Dextrorotatory. Its alcoholic solution is alkaline to litmus. $AuCl_3$ gives a yellowish pp. which soon turns purple. Paper moistened with an acid solution of the sulphate is turned green, and finally blue, by Cl_2O_4.

Salts.—$B'HCl$ aq: prisms.—$B'H_2PtCl_6$ 2aq.—$B'HClO_4$.—$B'HBr$ aq.—$B'HI$. S. 1·4 at 16°.—$B'HNO_3$.

Quinamidine $C_{19}H_{24}N_2O_2$. [93°]. $[\alpha]_D = 4·5°$ (in a 2 p.c. alcoholic solution). Formed by the action of acids upon quinamine (Hesse, *A*. 207, 299). Nodules; v. e. sol. alcohol. Not ppd. by NH_3 from acid solutions, but ppd. by NaOH. $AuCl_3$ gives a purple colour in solutions of its hydrochloride.—$B'HCl$ aq.—$B'_2H_2PtCl_6$ 6aq.—$B'HBr$ aq.—Oxalate $B'_2H_2C_2O_4$ 4aq.

Quinamicine $C_{19}H_{24}N_2O_2$. [109°]. $[\alpha]_D = 3·8°$ (in a 2 p.c. alcoholic solution). Formed by heating quinamine with dilute acids at 130° (Hesse, *A*. 207, 303). Amorphous, but gradually becomes crystalline. V. e. sol. alcohol. Dextrorotatory.—$B'_2H_2PtCl_6$ 3aq.

Protoquinamicine $C_{17}H_{20}N_2O_2$. Formed by heating dry quinamine acid sulphate at 130° (Hesse, *A*. 207, 305). Amorphous brown base.—$B'_2H_2PtCl_6$.

Apoquinamine $C_{19}H_{22}N_2O$. [114°]. Formed by boiling quinamine with excess of HCl (S.G. 1·125) for 3 minutes (Hesse, *A*. 207, 294). The alcoholic solution is inactive and neutral to litmus: the hydrochloride is lævorotatory.—$B'HCl$ ½aq.—$B'_2H_2PtCl_6$ 2aq.—$B'HNO_3$.—Oxalate $B'_2H_2C_2O_4$ aq.—Tartrate $B'_2C_4H_6O_6$ *x*aq.

Acetyl derivative $C_{19}H_{21}AcN_2O$. Amorphous.—$B'_2H_2PtCl_6$ 2aq.

Conquinamine $C_{19}H_{24}N_2O_2$. [123°]. $[\alpha]_D = 205°$ (in a 2 p.c. alcoholic solution). S. (91 p.c. alcohol) 13·5 at 19°; S. (ether) 13·5 at 15°; S. (benzene) 24·4 at 18°; S. (CS_2) 6·05 at 18°. Occurs in the bark of *C. succirubra* and *rosulenta*. It is best separated from quinamine through the greater solubility of its salts (Oudemans, *A*. 209, 38; Hesse, *A*. 209, 62).

Properties.—Long prisms or pyramids. It resembles quinamine in its reactions with H_2SO_4 and HNO_3. Gold chloride gives a golden pp. followed by a purple colouration. Heating with HCl forms apoquinamine $C_{19}H_{22}N_2$.

Salts.—$B'HCl$: octahedra, m. sol. water; $[\alpha]_D = 205°$.—$B'H_2PtCl_6$ 3aq (O.).—$B'H_2PtCl_6$ aq (H.).—$B'HClO_3$.—$B'HClO_4$.—$B'HBr$.—$B'HI$. S. 9·4 at 16°.—$B'HNO_3$.—$B'_2H_2SO_4$.—Formate $B'CH_2O_2$: monoclinic crystals.—Acetate $B'HOAc$: dimetric crystals.—Oxalate $B'_2H_2C_2O_4$ 3aq.—Quinate $B'C_7H_{12}O_6$ 2aq: prisms.

Quinidine $C_{20}H_{24}N_2O_2$. *Conquinine.* [168°]. $[\alpha]_D = 236·8 - 3p$ (in a *p* p.c. alcoholic solution). S. ·05 at 15°; S. (ether) 3 at 10°. Occurs in the bark of *Cinchona Calisaya*, *C. pitayensis*, and other species of *Cinchona* (van Heijningen, *A*. 72, 302; Pasteur, *C. R.* 36, 26; Stenhouse, *A*. 129, 15; Hesse, *A*. 146, 357; 166, 232; 174, 338; 176, 225; 182, 163; *B*. 10, 2154; 12, 425; Oudemans, *A*. 182, 53). By adding NaOH to the mother-liquors from which quinine sulphate has separated crude quinidine is ppd. Pure quinidine may be isolated from this by means of its iodide. Prisms (containing 2½aq) (from alcohol), rhombohedra (containing 2aq) (from ether), or laminæ (containing 1½aq) (from water). Its solution in dilute H_2SO_4 fluoresces blue. Chlorine-water and NH_3 give a green colour. Dilute H_2SO_4 at 100° changes it to quinicine. Conc. HCl converts it on heating into apoquinidine and apoquinidine chlorohydride. It is a febrifuge. It crystallises in trimetric forms with various alcohols: $B'MeOH$; $B'EtOH$; $B'PrOH$; $B'C_4H_9OH$; and $B'_2C_2H_4(OH)_2$ (Mylius, *B*. 19, 1773).

Salts.—$B'HCl$ aq. S. 1·6 at 10°; $[\alpha]_D = 212 - 2·56\,p$ (in a *p* p.c. alcoholic solution).—$B'H_2Cl_2$ aq: $[\alpha]_D = 250°$ in a 2 p.c. aqueous solution.—$B'H_2ZnCl_4$.—$B'_2H_2ZnCl_4$.—$B'_2H_2HgCl_4$.—$B'H_2PtCl_6$ aq.—$B'_2H_2PtCl_6$ 3aq.—$B'H_2AuCl_5$.—$B'HBr$. S. ·5 at 14° (de Vrij, *J. Ph.* [3] 32, 328).—$B'HI$. S. ·08 at 15°.—$B'H_2I_2$ 3aq. S. 1·1 at 15°.—$B'HNO_3$. S. 1·2 at 15°.—$B'AgNO_3$.—$B'_2H_2SO_4$ 2aq. S. 1 at 15°. $[\alpha]_D = 184°$ in a 3 p.c. solution in chloroform.—$B'H_2SO_4$ 4aq. S. 11·5 at 10°.—$B'_2H_2SO_4H_2I_6$ (Jörgensen, *J. pr.* [2] 14, 356; 15, 67).—$B'_4(H_2SO_4)_3H_2I_{10}$.—$B'_2H_2SeO_4H_2I_6$.—$B'_4(H_2SeO_4)_4H_2I_{12}$.—$B'_2H_2S_2O_3$ 2aq.—$B'H_3PO_4$.—$B'_2H_2CrO_4$ 6aq: large yellow plates (Hesse, *A*. 243, 144).—Oxalate $B'_2H_2C_2O_4$ aq. S. ·66 at 15°.—Succinate $B'_2C_4H_6O_4$ 2aq.—Tartrate $B'_2C_4H_6O_6$ aq. S. 2·6 at 15°.—Acid tartrate $B'C_4H_6O_6$ 3aq. S. ·25 at 10°.—$B'C_4H_5(SbO)O_6$ 4aq. S. ·18 at 10°.

Acetyl derivative $C_{20}H_{23}AcN_2O_2$. $[\alpha]_D = 128°$ in a 2 p.c. alcoholic solution at 15°. Amorphous.—$B'H_2PtCl_6$ 3aq.—$B'H_2Au_2Cl_8$ 2aq.

Methylo-iodide $C_{20}H_{24}N_2O_2MeI$: needles (Stahlschmidt, *A*. 90, 221).—$B'MeI_3$ [165°] (Jörgensen, *J. pr.* [2] 3, 153).

Ethylo-iodide $C_{20}H_{24}N_2O_2EtI$ (Stenhouse, *A*. 129, 20).—$B'EtI$ aq (Howard, *C. J.* 26, 1183).—$B'EtCl$ aq.—$B'EtHPtCl_6$.—$B'_2Et_2I_6H_2SO_4$.

Quinidine chloride $C_{20}H_{23}N_2OCl$. *Conquinine chloride.* [132°]. Formed by the action of PCl_5 upon the hydrochloride of quinidine (conquinine) (Comstock a. Königs, *B*. 18, 1223). Colourless crystals. V. sol. alcohol, benzene, and chloroform, sl. sol. ligroïn and dry ether. By boiling with alcoholic KOH it is converted into quiniëne $C_{20}H_{22}N_2O$.

Apoquinidine $C_{19}H_{22}N_2O_2$. *Apoconquinine.* [137°]. $[\alpha]_D = 155°$ (in a 2 p.c. alcoholic solution). Formed, together with MeCl, by heating quinidine with conc. HCl. White, amorphous powder (containing 2aq). Sol. alcohol and ether, $[\alpha]_D = 153·3$ $p = 2$, $t = 15°$ in 97 p.c. alcohol. The solution in dilute H_2SO_4 does not fluoresce, and gives no green colour with Cl and NH_3 (Hesse, *A*. 205, 326).

Hydrochloride: acicular crystals, v. sol. water.—$B'H_2PtCl_6$ 3aq: yellow flocculent pp.

Diacetyl derivative $C_{19}H_{20}Ac_2N_2O_2$. $[\alpha]_D = 40·4°$ in a 2 p.c. solution in 97 p.c. alcohol at 15°. Its sulphate fluoresces blue, and gives a green colour with Cl and NH_3.—$B'H_2PtCl_6$ 2aq: golden crystalline pp.

Apoquinidine chlorohydride $C_{19}H_{23}ClN_2O_2$. Formed by heating quinidine or apoquinidine with fuming HCl at 150°. Crystalline (with 2aq) or amorphous when anhydrous [164°]. Sol. ether and alcohol. $[\alpha]_D = 203·7°$ ($p = 2$, $t = 15$·97 v. p.c. alcohol). Does not give a green colour with Cl and NH_3.—$B'2HCl$.—$B'H_2PtCl_6$ 4aq.

Diacetyl derivative $C_{19}H_{21}Ac_2ClN_2O_2$. [168°]. Gives no green colour with Cl and NH_3. $[\alpha]_D = 95°$ in a 2 p.c. solution in dilute HCl.—$B'H_2PtCl_6$ 3aq.

Iso-quinidine $C_{20}H_{24}N_2O_2$. Formed by dissolving quinidine in conc. H_2SO_4 (Hesse, *A.* 243, 149). Long needles (from ether).—$B'_2H_2SO_4$ 8aq: needles.—$B'H_2PtCl_6$ 3aq: yellow flocculent pp.

Quiniëne $C_{20}H_{22}N_2O$. *Quinene.* [81°]. Formed by treatment of quinine or quinidine with PCl_5 followed by alcoholic KOH (Comstock a. Königs, *B.* 17, 1989; 18, 1223). Trimetric crystals (containing 2aq), $a:b:c = {\cdot}5322:1:{\cdot}6642$. The solution in dilute H_2SO_4 shows a greenish-blue fluorescence. By heating with HBr (or HCl) it is converted into apoquiniene $C_{18}H_{17}NO_2$.

Salts.—$B''H_2Cl_2ZnCl_2$ 2aq: trimetric prisms, $a:b:c = {\cdot}3424:1:{\cdot}4964$.—The tartrate is sl. sol. cold water, and well crystallised.

Dibromide $C_{20}H_{22}Br_2N_2O$. Obtained by addition of bromine to quiniëne. By boiling with alcoholic KOH it is converted into dehydroquiniëne $C_{20}H_{20}N_2O$. The *hydrobromide* $B''H_2Br_2$ 2aq forms yellow crystals, sl. sol. alcohol, aqueous HBr, or cold water (Comstock a. Königs, *B.* 20, 2516).

Dehydroquiniëne $C_{20}H_{20}N_2O$. Formed by boiling quiniëne-di-bromide with alcoholic KOH. Colourless crystals (with 3aq). V. sol. alcohol and ether, nearly insol. water. Dissolves in very dilute H_2SO_4 with a strong green-blue fluorescence. Gives the quinine reaction with chlorine and ammonia (Comstock a. Königs, *B.* 20, 2517).

Quinicine $C_{20}H_{24}N_2O_2$. [60°]. $[\alpha]_D = 44°$ (in a 2 p.c. chloroform solution). Occurs in cinchona bark (Howard, *C. J.* 24, 61; 25, 101). Formed by heating the sulphate of quinine or quinidine with H_2SO_4 at 130° (Pasteur, *C. R.* 37, 110; Hesse, *A.* 178, 245). Formed also by heating quinine or quinidine with glycerin at 200° (Hesse, *A.* 166, 277). Oil, which slowly solidifies. Sl. sol. water, v. sol. alcohol and ether. Its alcoholic solution is alkaline to litmus. Cl and NH_3 give a green colour. Its solution in dilute H_2SO_4 is not fluorescent.

Salts.—$B'H_2PtCl_6$ 2aq. — B'HI aq. — $B'_2H_2SO_4$ 3aq.—Oxalate $B'_2H_2C_2O_4$ 9aq. S. ·4 at 16°.—Acid tartrate $B'C_4H_6O_6$ 6aq. [100°]. Sulphocyanide B'HSCy ½aq.

Apoquiniëne $C_{18}H_{17}NO_2$. *Apoconquinine.* [246°]. Formed by heating quiniene with aqueous HBr (S.G. 1·5) at about 180° (Comstock a. Konigs, *B.* 18, 1226). Colourless crystals. V. sol. alcohol, sl. sol. water, ether, and benzene. It dissolves in aqueous acids and alkalis, forming yellow solutions. The sulphate is sparingly soluble. The hydrobromide forms small yellow crystals.

Cupreïne $C_{19}H_{22}N_2O_2$. [198°]. (Paul a. Cownley, *Ph.* [3] 15, 221; Hesse, *A.* 230, 55). Occurs in cuprea bark. The crude quinine sulphate from such bark is dissolved in aqueous H_2SO_4, excess of NaOH is added, and the ppd. quinine shaken out with ether. The aqueous liquid is warmed and neutralised with H_2SO_4. Cupreïne sulphate then separates (Hesse, *A.* 226, 240; 230, 57).

Properties.—Concentric prisms, containing 2aq (from ether). From alcohol it separates in the dry form. V. sl. sol. ether or chloroform, more sol. alcohol. The alcoholic solution is alkaline to litmus, gives a dark reddish brown colour with Fe_2Cl_6, and a deep green with chlorine water, followed by ammonia. The solution in dilute H_2SO_4 does not fluoresce, but gives with NH_3 a pp. slightly soluble in excess of NH_3, and easily soluble in NaOH. Ether extracts the base from the ammoniacal solution, but not from the solution in NaOH. It rotates light to the right almost as strongly as quinine. Its neutral salts form yellow solutions; its acid salts are colourless. HCl (S.G. 1·125) at 140° converts cupreïne into apoquinine, no MeCl being evolved.

Salts.—(Hesse, *A.* 230, 59.) $B''_2H_2SO_4$ 6aq. $B''H_2SO_4$ aq. — $B''HCl$ aq. — $B''(HCl)_2$. — $(B''HCl)_2PtCl_4$ 4aq. — $B''(HCl)_2PtCl_4$ aq. — $B''_2H_4C_6O_6$ 2aq. The base combines with NaOH and KOH (1 mol.), but not with NH_3. It also forms calcium, lead, and silver compounds.

Diacetyl derivative $C_{19}H_{20}Ac_2N_2O_2$ [88°]. Salt.—$C_{19}H_{20}Ac_2N_2O_2H_2PtCl_6$ 3aq.

Mono-methylo-compounds.—B''MeI. Is thrown down on adding MeI to alcoholic cupreïne solution. Colourless needles, very sparingly soluble in alcohol or water, insoluble in ether. Very soluble both in acids and alkalis.—B''MeCl.—$B''MeCl.HCl.PtCl_4$ 2aq.—$(B''Me)_2SO_4$. On adding baryta to a solution of the methylo-sulphate, and evaporating the filtrate, the hydroxide, (B''Me)OH, remains as a yellow amorphous residue. It has a bitter taste, is insoluble in ether, but very soluble in water. With a little bleaching-powder and ammonia it gives a green colour; if more bleaching-powder is used the colour is red.

Di-methylo-compounds B''2MeI 5aq forms orange plates (from water), soluble in acids, alkalis, and alcohol (though not in water). The corresponding hydroxide is only known in solution.

Hydrocupreïne $C_{19}H_{24}N_2O_2$. [169°]. Formed by heating hydroquinine sulphate with HClAq (S.G. 1·125) (Hesse, *A.* 241, 279). Microcrystalline powder (containing 2aq). Alkaline to litmus. A solution of its sulphate does not fluoresce—$B'_2H_2SO_4$: small needles, v. sl. sol. water and alcohol.—$B'_2C_4H_6O_6$ 2aq.—$B'H_2Cl_2$ aq. — $B'H_2PtCl_6$.

Homoquinine. This substance, obtained from *China cuprea* (the bark of *Remijia pedunculata*) (Howard a. Hodgkin, *C. J.* 41, 66), is also formed by adding sodium cupreine to quinine hydrochloride (Hesse, *A.* 230, 70). It is therefore a molecular compound of quinine and cupreine, $C_{20}H_{24}N_2O_2, C_{19}H_{22}N_2O_2$ 4aq.

Cuscamine. [218°]. An alkaloid in the bark of *Cinchona Pelletierana* (Hesse, *A.* 200, 304). Prisms; v. sol. ether, m. sol. alcohol.

Cusconine $C_{23}H_{26}N_2O_4$ 2aq. [110°]. S. (ether) 3 at 18°. $[\alpha]_D = -54°$ (in a 2 p.c. alcoholic solution). Occurs together with aricine in the bark of *C. cuprea* (Hesse, *A.* 185, 320; Paul a. Cownley, *Ph.* [3] 12, 497). Plates (containing 2aq) (from ether). Its acid solutions do not fluoresce. Lævorotatory. Conc. HNO_3 turns it dark green. $B'HHgCl_3$ 2aq. — $B'_2H_2PtCl_6$ 5aq: amorphous.—$B'_2H_2SO_4$ *x*aq.—B'HSCy 2aq: yellow powder.

Concusconine $C_{23}H_{26}N_2O_4$ aq. [144°]. When dry [c. 208°]. $[\alpha]_D = +40{\cdot}8°$ at 15° in 2 per cent. alcoholic solution. In bark of *Remijia Purdieana* (cuprea bark) (O. Hesse, *A.* 225, 234). Monoclinic crystals (containing aq). Sl. sol. alcohol, but ppd. by water from that solution. V. sol. benzene, ether, and chloroform; sl. sol. petroleum. Its alcoholic solution is neutral to litmus. At 150° it partly changes to an amorphous variety. It forms no acetyl derivative with Ac_2O. Conc.

HNO$_3$ added to its solution in acetic acid or HCl gives a splendid dark-green colour. Conc. H$_2$SO$_4$ forms a blue-green solution, turned olive-green on warming.

Salts.—Mostly gelatinous.—(B'HCl)$_2$PtCl$_4$ 5aq.—B'$_2$H$_2$C$_2$O$_4$.B'$_2$H$_2$SO$_4$. Prisms.

(α)-*Methylo-iodide* B'MeI. Crystalline powder: hardly sol. alcohol, sol. boiling water. From it may be obtained: B'MeCl, needles; (B'MeCl)$_2$PtCl$_4$, amorphous; (B'Me)$_2$SO$_4$; and B'MeOH, which when dry melts at [202°].

(β)-*Methylo-iodide* B'MeI. Gelatinous. V. sol. alcohol. From it may be obtained: B'MeCl, amorphous; (B'MeCl)$_2$PtCl$_4$5aq, amorphous; (B'Me)$_2$SO$_4$; and B'MeOH $2\frac{1}{2}$aq.

Cusconidine. An amorphous alkaloid in Cusco bark (Hesse, *A.* 200, 303).

Concusconidine C$_{23}$H$_{26}$N$_2$O$_4$. [124°]. A slightly dextrorotatory amorphous alkaloid, said to occur in cuprea bark (Hesse, *B.* 16, 62).—B''$_2$H$_2$PtCl$_6$.

Hydroquinine C$_{20}$H$_{26}$N$_2$O$_2$. [168°]. $[\alpha]_D = -142\cdot2°$ ($p = 2\cdot4$ in 95 p.c. alcohol at 20°, but $[\alpha]_D = -227\cdot1°$ in dil. HCl. Discovered by Hesse (*B.* 15, 856) in mother-liquors of quinine sulphate.

Preparation (Hesse, *A.* 241, 255).—The mother-liquor from quinine monosulphate is treated with successive quantities of sulphuric acid until a neutral salt is obtained containing over 30 p.c. of hydroquinine sulphate. The quinine is then removed with KMnO$_4$, and after neutralisation with NaOHAq the hydroquinine is extracted with ether, benzene, or chloroform.

Properties.—Can be obtained by neutralising the solution in dilute acid with NaOHAq as an amorphous pp. having the composition C$_{20}$H$_{26}$N$_2$O$_2$ 2aq. Crystallises from chloroform in concentric grouped needles. V. sol. alcohol, chloroform, ether, benzene, and CS$_2$, m. sol. ammonia, sl. sol. water, insol. NaOHAq. Solution in dilute H$_2$SO$_4$ shows blue fluorescence, and gives the same reactions as quinine with Cl and ammonia, but decolourises KMnO$_4$ very slowly. Alkaline reaction, bitter taste. Heated with HCl it yields hydrocupreine.

Salts.—B'$_2$H$_2$SO$_4$6aq: short white prisms; v. sol. alcohol and hot water, sl. sol. cold water, insol. ether. S. ·287 at 15°. $[\alpha]_D = -193\cdot1°$.—B'H$_2$SO$_4$ 3aq: long thin needles; v. sol. water and alcohol, m. sol. acetone. Heated to 120° it gives off water, and to 140° yields hydroquinicin sulphate.—B'$_2$H$_2$S$_2$O$_3$ 2aq.—B'HCl 2aq: long flat prisms; v. sol. water and alcohol, insol. ether.—B'$_2$PtCl$_6$H$_2$ 3aq: yellow amorphous pp.; v. sl. sol. water and alcohol.—B'PtCl$_6$H$_2$ 2aq.—B'2AuCl$_4$H 2aq(?): yellow amorphous pp.—B'2HClHgCl$_2$: small colourless flat needles.—B'BrH 2aq.—B'(BrH)$_2$ 3aq: B'HI: oil, becoming solid but not crystallising.—B'(IH)$_2$ 4aq: shining yellow needles.—B'H$_2$I$_6$ $x$aq: metallic, dichroic flat needles.—B'HCNS: a resin; m. sol. water.—B'C$_2$H$_4$O$_2$5aq. [100°]: small colourless needles; v. sol. water and alcohol.—Benzoate B'C$_7$H$_6$O$_2$: small needles; v. sol. alcohol, sl. sol. water.—Salicylate B'C$_7$H$_6$O$_3$: small colourless needles; v. sl. sol. cold water, m. sol. hot water, v. sol. alcohol.—Piperonylate B'C$_8$H$_6$O$_4$.—B'$_2$C$_2$O$_4$H$_2$ 6aq: long shining needles; insol. ether, v. sol. hot, sl. sol. cold, water, v. sol. alcohol. S. ·213 at 15°.—B'$_2$C$_4$H$_6$O$_6$ 2aq: thick colourless prisms; m. sol. hot water, alcohol, v. sol. chloroform-alcohol, sl. sol. water. S. ·183 at 17°. $[\alpha]_D = -176\cdot35°$ (*cf. Ph.* [3] 16, 1025).—Citrate B'$_3$C$_6$H$_8$O$_7$ 10aq: small white needles; v. sol. boiling, sl. sol. cold, water.—B'$_2$PO$_4$H$_3$ 7aq: small white needles; sl. sol. water.—B'$_3$(AsO$_4$H$_3$)$_2$ 10aq: long white needles.—B'$_2$CrO$_4$H$_2$ 6aq: long golden needles; m. sol. hot, sl. sol. cold, water, v. sl. sol. chloroform.

Combinations.—1. With cupreïne C$_{20}$H$_{26}$N$_2$O$_2$.C$_{19}$H$_{22}$N$_2$O$_2$ 2aq; long shining needles grouped concentrically.—2. With quinidine C$_{20}$H$_{26}$N$_2$O$_2$.C$_{20}$H$_{24}$N$_2$O$_2$ $2\frac{1}{2}$aq; white needles.—3. With anethol (C$_{20}$H$_{26}$N$_2$O$_2$)$_2$C$_{10}$H$_{12}$O 2aq. Large shining dimetric prisms. V. sol. hot alcohol, ether; sl. sol. cold alcohol; insol. water. Decomposes at 120° into hydroquinine, anethol, and water.—4. Also forms compounds with hydroquinidine, cinchonidine, hydrocinchonidine, and homocinchonidine, but not with cinchonine or hydrocinchonine.

Methylo-compounds B'MeIEtOH. Pale yellow prisms. [218°]. V. sol. hot, m. sol. cold alcohol, insol. water.—B'MeCl 2aq [168°].—B'MeHPtCl$_6$ 2aq: orange-red needles.—B'$_2$Me$_2$PtCl$_6$: pale-yellow needles; m. sol. alcohol and water.—B'MeOH: resin; insol. ether and chloroform; v. sol. alcohol and water. Absorbs CO$_2$.

Acetyl derivative C$_{20}$H$_{25}$N$_2$O$_2$Ac. [c. 40°]. V. sol. ether, alcohol, benzene, acetone, and acids; sl. sol. water, and NH$_3$. $[\alpha]_D = -73\cdot9°$. in 3 molecules HClAq $p = 3$, $t = 15°$.—(C$_{20}$H$_{25}$AcN$_2$O$_2$)PtCl$_6$H$_2$ 2aq: powdery pp.; sl. sol. dil. HCl and water.—(C$_{20}$H$_{25}$AcN$_2$O$_2$)$_2$SO$_4$H$_2$ 9aq: long needles; v. sol. hot water, alcohol, sl. sol. cold water, insol. ether.

Sulphonic acid.—Strong H$_2$SO$_4$ at ordinary temperatures forms hydroquinine sulphonic acid C$_{20}$H$_{25}$N$_2$O$_2$.SO$_3$H aq [239°]; insol. ether, chloroform; sl. sol. NH$_3$ and NaOHAq.—(C$_{20}$H$_{25}$N$_2$O$_2$.SO$_3$H)PtCl$_6$H$_2$ 8aq: pale-yellow needles.

Hydroquinicine C$_{20}$H$_{26}$N$_2$O$_2$. Formed by fusing hydroquinine sulphate at 140° (Hesse, *A.* 241, 273). Yellow resin. V. sol. ether, alcohol, chloroform and dilute acids. Solution in dilute H$_2$SO$_4$ is intensely yellow, addition of chlorine-water and ammonia gives a yellowish green colouration. More easily acted on by KMnO$_4$ than hydroquinine.—Salts.—Neutral sulphate; white needles, v. e. sol. alcohol and water.—B'PtCl$_6$H$_2$ aq: pale yellow flocculent pp. changing to orange-coloured crystals insol. water, sl. sol. dilute HCl.

Hydroquinidine C$_{20}$H$_{26}$N$_2$O$_2$. *Hydroconquinine.* [167°]. Occurs in crude quinidine, and obtained therefrom by treatment in acid solution with KMnO$_4$ which does not attack hydroquinidine (Forst a. Böhringer, *B.* 14, 1954; 15, 519, 1656; Hesse, *B.* 15, 854). Needles or tables. M. sol. ether, v. sol. alcohol and chloroform. The alcoholic solution is alkaline to litmus. Its solution in dilute H$_2$SO$_4$ shows blue fluorescence. It is dextrorotatory. Chlorine-water and NH$_3$ give a green colour. Chromic mixture forms quinic acid.

Salts.—B'HCl: soluble prismatic tables.—B'HBr: plates, sl. sol. cold water.—B'H$_2$PtCl$_6$ 2aq. B'$_2$H$_2$SO$_4$ 12aq.—B'HI.—B'H$_2$I$_2$ 3aq: large orange soluble crystals.—Tartrate B'$_2$C$_4$H$_6$O$_6$ 2aq: glistening soluble prisms.—Acid tartrate

$B'C_4H_6O_6$ 3aq: thin white needles, sl. sol. cold water.—Benzoate $B'C_7H_6O_2$: colourless tables.—Salicylate $B'C_7H_6O_3$: six-sided tables.

Hydrocinchonidine. Identical with CINCHAMIDINE (*v.* CINCHONA BASES).

Homocinchonidine $C_{19}H_{22}N_2O$. [206°]. S. (alcohol) 4·9 at 13°; S. (ether) ·46 at 15°. $[\alpha]_D = -107^\circ$ in a 2 p.c. alcoholic solution at 5°. Occurs in very small quantity in many cinchona barks, especially that of *C. rosulenta* (Hesse, *B.* 14, 46, 1891; *A.* 205, 203; 207, 310; *cf.* Skraup, *A.* 199, 365). Obtained by recrystallisation of crude cinchonidine sulphate. Prisms or plates. Lævorotatory. Its alcoholic solution is alkaline to litmus. Its solution in H_2SO_4 does not fluoresce. It gives no green colour with Cl and NH_3. Conc. HCl at 150° gives apocinchonidine and apocinchonidine chlorohydride. $KMnO_4$ forms formic acid and cinchotenidine.

Salts.—B'HCl aq.—B'HCl 2aq. $[\alpha]_D = -139^\circ$.—$B'H_2PtCl_6$ aq.—$B'_2H_2PtCl_6$ 2aq.—$B'HNO_3$ aq.—$B'_2H_2S_2O_3$ 2aq. S. ·5 at 13°.—$B'_2H_2SO_4$ 6aq. S. 1·15 at 22°. $[\alpha]_D = -138^\circ$ in an 8 p.c. aqueous solution.—B'HSCy.—Tartrate $B'C_4H_6O_6$ 2aq. S. ·075 at 10°.—Quinate $B'C_7H_{12}O_6$.—Phenyl sulphate B'_2HSO_4Ph 5aq.

Acetyl derivative $C_{19}H_{21}AcN_2O$. $[\alpha]_D = -34^\circ$ in a 2 p.c. alcoholic solution at 15°.—$B'H_2PtCl_6$ 2aq.—$B'(HAuCl_4)_2$ aq.

Cinchotenidine $C_{18}H_{20}N_2O_3$. [256° cor.]. S. (alcohol) ·13 at 78°. Formed by oxidation of homocinchonidine or cinchonidine (Skraup a. Vortmann, *A.* 197, 235; Hesse, *B.* 14, 1892). Needles or prisms (containing 3aq). Its solution in dilute H_2SO_4 does not fluoresce. Its solution in HClAq is lævorotatory. $[\alpha]_D = -201^\circ$.—$B'_2H_2PtCl_6$.—$B'_2H_2SO_4$ 2½aq; v. e. sol. water.

Diconquinine $C_{40}H_{46}N_4O_3$. An amorphous alkaloid occurring in most cinchona barks (Hesse, *B.* 10, 2155). Is the chief constituent of commercial 'quinoidine.' Dextrorotatory. Gives a green colour with Cl and NH_3. The solution in dilute H_2SO_4 is fluorescent. Its salts are amorphous.

Paricine $C_{16}H_{18}N_2O$. [130°]. Found by Winkler (*B. J.* 27, 338) in a false cinchona bark. Occurs in the bark of *C. lutea*, and *C. succirubra* of Darjeeling (Hesse, *A.* 166, 263; *Ph.* [3] 9, 839). The aqueous solution of the mixed sulphates of quinine, cinchonine, paricine, &c. is treated with conc. HNO_3 which throws down paricine nitrate. Paricine may also be ppd. from the mixed sulphates by adding Na_2CO_3 to feeble alkaline reaction. Yellow powder. V. e. sol. alcohol and ether. The alcoholic solution is alkaline to litmus and is inactive.—$B'_2H_2PtCl_6$ 4aq.

Javanine. Occurs in the bark of *C. Calisaya javanica* (Hesse, *B.* 10, 2162). Plates (from water). Its solution in dilute H_2SO_4 is intensely yellow.

CINCHONIC ACID *v.* QUINOLINE-(*Py.* 1)-CARBOXYLIC ACID.

CINCHONIDINE $C_{19}H_{22}N_2O$. [200°] (H.); [210° cor.] (S. a. V.). S. ·06 at 10°. S. (ether) ·53 at 15°; S. (97 p.c. alcohol) 6·1 at 13°. $[\alpha]_D = -70^\circ$ in a 4 p.c. solution in alcohol-chloroform. Discovered by Winkler (*Repert. Pharm.* [2] 48, 384; 49, 1) and occurs in most cinchona barks (Leers, *A.* 82, 147; Pasteur, *C. R.* 37, 110; *C. J.* 6, 275; Bussy a. Guibourt, *J. Ph.* [3] 22, 401; Hesse, *A.* 135, 333; 166, 240; 176, 203; 181, 50; 182, 160; 205, 196; 207, 310; Skraup a. Vortmann, *A.* 197, 226). Separated from quinine and other bases by repeated extraction with ether. It is then converted into the hydrochloride and ppd. by hydrosodic tartrate. The base, liberated from the tartrate, is then crystallised from alcohol.

Properties.—Gives no green colour with chlorine water and ammonia. Its solution in dilute H_2SO_4 does not fluoresce.

Reactions.—1. HNO_3 gives the same products as with cinchonine. CrO_3 does the same.—2. H_2SO_4 at 130° or glycerin at 200° converts it into cinchonicine.—3. Heating with HCl gives apocinchonidine, (β)-cinchonidine, and apocinchonidine chloro-hydride.—4. Oxidised by $KMnO_4$ to pyridine tri-carboxylic acid. [257°] (Ramsay a. Dobbie, *C. J.* 35, 189).—5. PCl_5 converts it into cinchonidine-chloride $C_{19}H_{21}N_2Cl$, which by boiling with alcoholic KOH gives cinchene $C_{19}H_{20}N_2$, and this by heating with HCl at 220° is converted into apocinchene $C_{18}H_{17}NO$ (Comstock a. Konigs, *B.* 17, 1986).

Salts.—B'HCl aq: monoclinic crystals. S. 3·3 at 10°. S. (ether) ·3 at 10°. Lævorotatory. $[\alpha]_D$ varies from −24° (in chloroform) to −152° (in dilute HClAq).—B'HCl 2aq: prisms.—$B'H_2Cl_2$ aq.—$B'H_2HgCl_4$: scales.—$B'H_2PtCl_6$ aq. $B'H_2PtCl_6$ 2aq.—$B'H_2AuCl_5$.—$B'H_2I_2$ aq.—$B'HNO_3$ aq. S. 1·4 at 10°.—$B'_2H_2SO_4$ 6aq. S. 1 at 12°; 1·5 at 22°: prisms. $[\alpha]_D = -111^\circ$ (in water).—$B'H_2SO_4$ 5aq: striated prisms, v. sol. water and alcohol.—$B'(H_2SO_4)_2$ 2aq: short prisms, sl. sol. cold water.—$B'H_2S_2O_3$ 2aq. S. ·45 at 10°.—$B'_{12}(H_2SO_4)_9H_8I_{32}$ 8aq: golden plates (Herapath, *C. J.* 9, 130; Jörgensen, *J. pr.* [2] 14, 371).—$B'_4(H_2SO_4)_2H_3I_9$ 4aq.—$B'_8(H_2SO_4)_5H_6I_{18}$ 6aq. $B'_2H_2SO_4HI_5$ aq.—$B'_{12}(H_2SeO_4)_9H_8I_{32}$ 8aq.—$B'_2H_2SeO_4HI_5$ aq.—$B'_3(H_3PO_4)_2$ 12aq.—$B'_2(H_3PO_4)_2HI_5$.—$B'_2(H_3AsO_4)_2$.—B'HSCy. S. ·5 at 20°. Acetate B'HOAc aq.—Benzoate $B'C_7H_6O_2$. S. ·3 at 10°.—Oxalate $B'_2H_2C_2O_4$ 6aq. S. ·4 at 10°. $[\alpha]_D = -99^\circ$.—$B'_2H_2C_2O_4H_2I_6$.—Succinate $B'_2C_4H_6O_4$ 2aq. S. ·17 at 10°. Tartrate $B'_2C_4H_6O_6$ 2aq: crystalline pp.; insol. aqueous sodio-potassium tartrate. S. ·04 at 10° (tartrate of cinchonine is far more soluble).—$B'_2C_4H_6O_6HI_3$.—Acid tartrate $B'(C_4H_6O_6)_2$ 3aq.—Salicylate $B'C_7H_6O_3$. S. ·13 at 18°.

Combinations with Phenol.—B'_2HOPh. Prisms. Formed by mixing alcoholic solutions of phenol and cinchonidine.—$B'_2(HOPh)_4$: unstable crystals.—B'HClHOPh aq: crystalline grains, formed by adding phenol to an aqueous solution of cinchonidine hydrochloride.—B'_2SO_4HOPh 5aq. Formed by mixing hot aqueous solutions of phenol and cinchonidine sulphate. Prisms. S. ·235 at 15°.

Acetyl derivative $C_{19}H_{21}AcN_2O$. [42°]. $[\alpha]_D = -38^\circ$ in a 2 p.c. alcoholic solution at 15°; $= -81^\circ$ in a solution in dilute HCl. Brittle mass.—$B'H_2PtCl_6$ 2aq.—$B'(HAuCl_4)_2$ aq.

Methyl-cinchonidine $C_{19}H_{21}MeN_2O$. [76°]. From the iodide by treatment with aqueous KOH (Stahlschmidt, *A.* 90, 218; Claus a. Bock, *B.* 13, 2191; Hesse, *B.* 14, 45). Needles or tables (containing aq). Its salts are mostly deliquescent. Iodide $C_{19}H_{21}MeN_2OHI$. [248°]. From cinchonidine and MeI. Slender needles.—

Chloride B'HCl. [158°]. Slender needles (containing aq).—$B'H_2PtCl_6$ 3aq.

Methylo-iodide $C_{19}H_{21}MeN_2O.MeI$ 2aq: crystals.

Methylo-di-iodide $C_{19}H_{21}MeN_2O.HI.MeI$: large prisms.

Ethyl-cinchonidine $C_{22}H_{28}N_2O$. [90°]. Colourless needles. V. sol. alcohol and ether, insol. water. Prepared by the action of aqueous KOH on the iodide (Claus a. Dannenbaum, *B.* 18, 2189).

Salts.—B'HCl 3aq: cubes; v. sol. water and alcohol (Howard, *C. J.* 26, 1181; Claus, *B.* 14, 1922). Lævorotatory.—B'HBr aq.—B'HI. [261°]. From cinchonidine and EtI. Needles. $B'HI_3$.—B'HCy. [140°]. Slender needles, v. sol. water (Claus a. Merck, *B.* 16, 2745).—$B''H_2Cl_2PtCl_4$ aq: crystalline pp.

Methylo-iodide BMeI. Colourless needles. Decomposes at 257°.

Ethylo-iodide BEtI. Resembles the methylo-iodide; on treatment with KOH it gives a di-ethyl-cinchonidine.

Ethylo-di-iodide $C_{19}H_{21}EtN_2OHEtI_2$aq. [255°]. Golden crystals.

Isoamyl-cinchonidine $C_{19}H_{21}(C_5H_{11})N_2O$. Resin.—$B'H_2PtCl_6$ *x*aq (Claus a. Weller, *B.* 14, 1922).

Di-bromo-cinchonidine $C_{19}H_{20}Br_2N_2O$. From cinchonidine in CS_2 and Br (Skalweit, *A.* 172, 103).—$B'H_2Br_2$: needles, v. sol. alcohol.

Di-oxy-cinchonidine $C_{19}H_{20}(OH)_2N_2O$. From the preceding by long boiling with alcoholic KOH (S.). Ramified crystals.—$B'_2H_2SO_4$2aq: plates.—$B'H_2SO_4$.—$B'H_2PtCl_6$.

Apocinchonidine $C_{19}H_{22}N_2O$. [225°]. $[\alpha]_D = -129°$ in a $\frac{3}{5}$ p.c. alcoholic solution at 15°. Formed by heating cinchonidine with HCl (6 pts. of S.G. 1·105) at 150° (Hesse, *A.* 205, 327). Small plates (from alcohol). Lævorotatory. Its acid solutions do not fluoresce.—$B'H_2PtCl_6$2aq.

Acetyl derivative $C_{19}H_{21}AcN_2O$. $[\alpha]_D = -62°$ in a 2 p.c. alcoholic solution at 15°.—$B'H_2PtCl_6$2aq.—$B'(HAuCl_4)_2$ aq.

Apocinchonidine chlorohydride $C_{19}H_{23}ClN_2O$. [200°]. $[\alpha]_D = -142°$ in a 2 p.c. solution of dilute HCl (containing 3HCl). From apocinchonidine and fuming HCl at 150° (Zorn, *J. pr.* [2] 8, 283; Hesse, *A.* 205, 346). Plates (from alcohol). Lævorotatory.—$B'H_2Cl_2$.—$B'H_2PtCl_6$2aq.

Acetyl derivative $C_{19}H_{22}AcClN_2O$. [150°]. Prisms (from ether). Lævorotatory.—$B'H_2PtCl_6$2aq.

(β)-Cinchonidine $C_{19}H_{22}N_2O$. [207°]. $[\alpha]_D = -181°$ in a $1\frac{1}{4}$ p.c. solution in dilute HCl at 15°. Formed, together with apocinchonidine, by heating cinchonidine with HCl (S.G. 1·105) at 140°. Separated from apocinchonidine through the insolubility of its tartrate (Hesse, *A.* 205, 327). Short prisms or plates. Lævorotatory. The neutral **tartrate** is v. sl. sol. water. By heating with HCl for a long time it changes to apocinchonidine.—$B'H_2PtCl_6$aq.

Iso-cinchonidine $C_{19}H_{22}N_2O$. [235°]. Formed by dissolving cinchonidine in conc. H_2SO_4 (Hesse, *A.* 243, 149). Colourless plates. V. sl. sol. ether, v. sol. alcohol and chloroform.

CINCHONINE $C_{19}H_{22}N_2O$. [236°] (when slowly heated); [248°–252°] (when quickly heated) (Hesse); [260°] (Skraup). $[\alpha]_D = 226°$ in a 1 p.c. alcoholic solution; $= 255°$ in dilute H_2SO_4; $= 268°$ in a 10 p.c. solution containing 1 mol. H_2SO_4 at 15° (Hesse; *cf.* Oudemans, *Ar. Néerl.* 10, 193). S. ·262 at 10°; S. (alcohol of S.G. ·852) ·71 at 10°; S. (ether) ·27 at 10°; S. ($CHCl_3$) ·28. Occurs, together with quinine, in most of the true cinchona barks (Fourcroy, *Ann. Chim.* 8, 113; 9, 7; Vauquelin, *Ann. Chim.* 59, 30, 148; Gomez, *Edinb. Med. and Surg. Journal*, 1811, 420; Pfaff, *Schw. J.* 10, 365; Pelletier a. Caventou, *A. Ch.* 15, 291, 337; Pelletier a. Dumas, *A. Ch.* 24, 169; Gerhardt, *Revue scient.* 10, 886; *Traité*, 4, 105; Laurent, *A. Ch.* [3] 19, 363; Regnault, *A. Ch.* 68, 113; *A.* 26, 15; Liebig, *A.* 26, 49; Hlasiwetz, *A.* 77, 49; Weidel, *A.* 173, 76; Hesse, *A.* 122, 226; 135, 326; 166, 217; 205, 211; Skraup, *A.* 197, 353; Oudemans *A.* 182, 44).

Preparation.—The bark is extracted with dilute acid. The alkaloids are ppd. by lime, Na_2CO_3, or NaOH, and crystallised from alcohol (85 p.c.). Cinchonine crystallises out before quinine, unless the quantity of the latter present be relatively large, in which case a portion of the quinine is first removed by crystallisation of the sulphates. Quinine may be separated from cinchonine by ether, which dissolves quinine most readily.

Properties.—Prisms (from alcohol). When ppd. by ammonia from aqueous solutions of its salts it is amorphous, but rapidly becomes crystalline. Tastes bitter. Its solutions are alkaline to litmus and dextro-rotatory. Its solution in dilute H_2SO_4 does not fluoresce. It does not give a green colour with chlorine-water and ammonia. It gives a yellow pp. with chloride of iodine.

Reactions.—1. Oxidised by $KMnO_4$ to pyridine tri-carboxylic acid (Dobbie a. Ramsay, *C. J.* 35, 189). 10 g. cinchonine dissolved in 4·5 g. H_2SO_4, diluted with water to 100 c.c., and treated gradually with 285 c.c. of a 5 p.c. solution of $KMnO_4$ gives cinchotine, cinchotenine, and quinoline carboxylic acid (Skraup, *A.* 201, 294). In the syrupy oxidation products of cinchonine are a monobasic acid $C_8H_{13}NO_4$, a base $C_9H_{17}NO_2$, yielding an ethyl-pyridine identical with that of Wyschnegradsky, C_9H_7NO, identical with Schmideberg a. Kretschy's base kynurine, and an amorphous product $C_{13}H_{13}NO_2$ (Skraup, *M.* 7, 517, 518). Alkaline $KMnO_4$ gives off 41 p.c. of the nitrogen as NH_3 (Hoogewerff a. Van Dorp, *A.* 204, 90).—2. H_2SO_4 and PbO_2 give a red substance, cinchonetin (Marchand, *J. Chim. Med.* 10, 362).—3. Boiling HNO_3 (S.G. 1·4) forms quinoline carboxylic (cinchonic) acid, quinolic acid $C_9H_6N_2O_6$, pyridine dicarboxylic (cinchomeronic) acid, pyridine tri-carboxylic acid and a base $C_{16}H_{18}N_2O_5$ (Weidel, *A.* 173, 76).—4. CrO_3 gives quinoline carboxylic acid and some formic acid, which perhaps indicates a methoxyl group (Skraup, *A.* 201, 294).—5. PCl_5 converts it into cinchonine-chloride $C_{19}H_{21}N_2Cl$ [52°], which by boiling with alcoholic KOH gives cinchene $C_{19}H_{20}N_2$, and this by heating with HCl at 220°–230° is converted into apocinchene $C_{18}H_{17}NO$ by splitting off MeCl and NH_3 and taking up H_2O (Comstock a. Königs, *B.* 17, 1984).—6. Treatment with CuO and KOH gives quinoline and a resin whence oxidation produces pyridine dicarboxylic acid (Wyschnegradsky, *B.* 13, 2318). 7. Distillation with solid *potash* yields methylamine, (α) **and** (β) di-methyl-pyridine, (α) and (β) tri-methyl-pyridine, quinoline, and quinoline tetrahydride (Oechsner de Coninck, *A. Ch.* [5] 27, 453; *C. R.* 94, 87).—8. Aqueous KOH gives quinoline and a solid body (Butlerow, *J. R.* 10, 244); in presence of superheated steam KOH forms also methyl-quinoline (Krakau, *Bl.* [2] 45, 248).—9. H_2SO_4 and a little water at 130° forms the isomeric cinchonicine; this body is also formed by fusing the acid sulphate of cinchonine. According to Jungfleisch a. Léger (*C. R.* 105, 1255) pure sulphate of cinchonine dissolved in a mixture of equal parts of water and pure H_2SO_4 yields a colourless liquid, which when heated for some time to 120° and then rendered alkaline yields a pp. of six bases: cinchonibine ($\alpha_D = +175\cdot8°$ in a $\frac{3}{4}$ p.c. alcoholic solution), cinchonifine ($\alpha_D = +195°$), cinchonigine ($\alpha_D = -60°$), cinchoniline ($\alpha_D = +53°$), all having the formula $C_{38}H_{22}N_2O_2$, and the two oxycinchonines ($\alpha_D = +182\cdot56°$ and $\alpha_D = +187\cdot14°$) of the formula $C_{38}H_{22}N_2O_4$. Fuming H_2SO_4 forms cinchonine sulphonic acid.—10. HCl at 150° forms successively apocinchonine, diapocinchonine, and finally apocinchonine chlorohydride.—11. The product of the action of *sodium ethylate* on cinchonine, after distilling with steam, yields $C_{20}H_{26}N_2$, a heavy reddish yellow viscous oil smelling like quinoline. The constitution of this base is probably $C_{18}H_{21}N_2(C_2H_5)$ (Michael, *Am.* 7, 182).—12. Conc. HBrAq forms apocinchonine bromohydride $C_{19}H_{21}BrN_2O$ and the hydrobromide of that body $C_{19}H_{23}BrN_2OH_2Br_2$ (Skraup, *A.* 201, 324).

Salts.—$B'HCl$2aq. S. 4·2 at 10°; S. (alcohol) 77 at 16°; S. (ether) ·35. $[\alpha]_D = 163°$ in a 1 p.c. aqueous solution; = 212° in presence of 2 mol. HCl (Hesse; *cf.* Schwabe, *J. Ph.* [3] 38, 389).—$B'H_2Cl_2$.—$B'HCl$.—$B'H_2F_2$ $\frac{1}{2}$aq (Elderhorst, *A.* 74, 80).—$B'H_2HgCl_4$: formed by mixing alcoholic solutions of cinchonine hydrochloride and of $HgCl_2$ (Hinterberger, *A.* 77, 201). Needles.—$B'H_2ZnCl_4$ aq.—$B'_2H_6ZnCl_8$ 3aq.—$B'_2H_6ZnCl_8$ aq.—$B'H_2SnCl_4$.—$B'H_2PtCl_6$: amorphous pp.—$B'H_2PtCl_6$ aq.—$B'H_2PtCl_6$ 2aq.—$B'H_2AuCl_5$.—$B'HClO_3$: bulky crystalline tufts (Serullas, *A. Ch.* [2] 45, 278).—$B'(HClO_4)_2$ aq (Bödecker, *A.* 71, 59; Dauber, *A.* 71, 66).—$B'H_2Br_2$.—$B'HI$ aq.—$B'H_2I_2$ aq.—$B'HI_3$ (Bauer, *Ar. Ph.* [3] 5, 289; *cf.* Pelletier, *A. Ch.* [2] 63, 181).—$B'HI_3$ aq [92°]; trimetric brown tables (from alcohol) (Jörgensen, *J. pr.* [2] 3, 145; 15, 82).—$B'HClH_3I_7$ [97°].—$B'H_2HgI_4$ (Caillot, *B. J.* 10, 193).—$B'_8(H_2SO_4)_6H_6I_{16}$2aq. [140°-145°] (Jörgensen, *J. pr.* [2] 14, 356; *cf.* Herapath, *C. J.* 9, 151).—$B'_4(H_2SO_4)_2H_4I_{14}$.—$B'_2H_2SO_4H_2I_8$. $B'_2H_2SeO_4H_2I_8$.—$B'(H_2C_2O_4)_2H_4I_{14}$.—$B'HIO_3$. Explodes at 120°.—$B'H_4FeCy_6$ 2aq: formed by mixing alcoholic solutions of cinchonine and H_4FeCy_6; lemon-yellow pp.; v. sl. sol. alcohol (Dollfus, *A.* 65, 224).—$B'H_3FeCy_6$ 2aq: orange pp., formed by adding aqueous K_3FeCy_6 to aqueous cinchonine hydrochloride—$B'HSCy$.—$B'HNO_3$ aq: prisms, v. sol. water. $[\alpha]_D = 172°$ Bouchardat).—$B'_2H_2SO_4$ 2aq. Hard prisms. S. 1·5 at 13°. $[\alpha]_D = 169°$ in a 1 p.c. aqueous solution; = 193° in a 1 p.c. alcoholic solution (Hesse). $[\alpha]_D \div [\alpha]_0 = 1\cdot268$ (Grimbert, *J. Ph.* [5] 16, 295). $B'H_2SO_4$ 3aq: trimetric octahedra (Baup, *A. Ch.* [2] 27, 323).—$B'H_2SO_4$ 4aq.—$B'_2H_2S_2O_3$ 2aq.—$B'_2H_2S_2O_8$ aq.—$B'_2H_2Cr_2O_7$.—$B'_2H_3PO_4$ 12aq.—$B'_2H_3AsO_4$ 12aq.—**Oxalate** $B'H_2C_2O_4$ 2aq. S. 1 at 16° (Pasteur, *J.* 1853, 419).—**Lævotartrate** $B'C_4H_6O_6$ aq. S. (alcohol) ·3 at 19°; v. sl. sol. water.—**Citrate** $B'_3C_6H_8O_7$ 4aq. S. 2·1 at 12°. **Acid citrate** $B'_2C_6H_8O_7$ 4aq. S. 1·8 at 15°.—**Urate** $B'C_5H_4N_4O_3$ 4aq.—**Picrate** $B'_2(C_6H_2(NO_2)_3(OH))_2$.—**Benzoate** $B'HOBz$. S. ·6 at 15°.

Acetyl derivative $C_{19}H_{21}AcN_2O$. $[\alpha]_D = 114°$ in a 2 p.c. alcoholic solution. Amorphous; v. sol. alcohol and ether.—$B'H_2PtCl_6$ aq. $B'(HAuCl_4)_2$ aq.

Benzoyl derivative $C_{19}H_{21}BzN_2O$. Amorphous (Schützenberger, *A.* 108, 351).—$B'H_2PtCl_6$ *x*aq.

Methyl-cinchonine $C_{19}H_{21}MeN_2O$. [74°]. From cinchonine by successive treatment with MeBr and aqueous KOH (Claus, *B.* 13, 2286; *cf.* Stahlschmidt, *A.* 90, 218). Tables (from ether). $B'HBr$ aq. *Cinchonine methylo-bromide.* [248°]. From cinchonine and MeBr. Said not to be identical with the compound of methyl-cinchonine with HBr.—$B'HI$ [254°].—$B'HI_3$ [162°].—$B'H_2PtCl_6$ aq.—$B'HMeBr_2$ [235°]. From cinchonine (1 mol.) and MeBr (2 mols.) at 150°. $B'MeI$. [201°]; needles.—$B'Me_2I_2$. [235°].

Ethyl-cinchonine $C_{22}H_{28}N_2O$. [50°]. Crystalline solid. Prepared by the action of alcoholic KOH on cinchonine-ethylo-iodide (Claus a. Kemperdick, *B.* 13, 2286; *cf.* Howard, *C. J.* 26, 1183).

Salts.—$B'HI$. [260°]. *Cinchonine ethylo-iodide.* White needles. From cinchonine and EtI.—$B'HCl$ aq.—$B'HBr$.—$B'HI_3$ [142°] (Jörgensen, *J. pr.* [2] 3, 152).—$B'H_2Cl_2PtCl_4$ 2aq: yellow pp. The gold double chloride forms small yellow plates.

Ethylo-iodide $B'EtI$. [242°]. From ethyl-cinchonine and EtI. Fine white needles. With KOH it gives di-ethyl-cinchonine. $B'HEtI_2$. *Cinchonine di-ethylo-iodide*: $B'Et_2I_2$ aq. [264°]. Yellow prisms sol. water.

Benzyl-cinchonine $C_{26}H_{28}N_2O$. [117°]. Colourless needles. Prepared by the action of KOH on cinchonine-benzylo-chloride (Claus a. Treupel, *B.* 13, 2294).—$B'HCl$. *Cinchonine benzylo-chloride.* [248°]. From cinchonine and C_7H_7Cl in alcohol. Needles, sol. hot water and alcohol. Ag_2O converts it into $C_{19}H_{21}(C_7H_7)N_2O$ aq said not to be identical with the isomeride got by the action of KOH (Claus).—**Carbonate** [115°].—$B'H_2Cl_2PtCl_4$ 2aq: yellow crystalline pp.

Benzylo-chloride $B'C_7H_7Cl$: [255°]; colourless needles.

Di-chloro-cinchonine $C_{19}H_{20}Cl_2N_2O$. The hydrochloride is ppd. by passing chlorine into a conc. solution of cinchonine hydrochloride (Laurent, *A. Ch.* [3] 24, 302). Crystalline.—$B'H_2Cl_2$. S. (alcohol) 2.—$B'H_2PtCl_6$ aq.—$B'H_2Br_2$.

Bromo-cinchonine $C_{19}H_{21}BrN_2O$. Formed by adding Br to an alcoholic solution of cinchonine (Laurent, *A. Ch.* [3] 24, 302; A. Kopp, *Ar. Ph.* [3] 9, 34). Boiling alcoholic KOH gives 'oxy-cinchonine' [205°].—$B'H_2Cl_2$.

Di-bromo-cinchonine $C_{19}H_{20}Br_2N_2O$. Formed by bromination of cinchonine (Comstock a. Königs, *B.* 17, 1995; *cf.* Laurent, *Compt. chim.*

1849, 311). Colourless crystals containing aq. Sl. sol. alcohol, insol. water. Alcoholic KOH is said by H. Strecker (*A.* 123, 380) to convert it into an oxycinchonine which crystallises from alcohol in plates.

Cinchonine-(α)-di-bromide $C_{19}H_{22}N_2Br_2O$. Formed by the action of bromine upon cinchonine dissolved in a mixture of chloroform and spirit. Crystallises with aq. Boiled with alcoholic KOH it is converted into dehydrocinchonine $C_{19}H_{20}N_2O$. — $C_{19}H_{22}N_2Br_2O,H_2Br_2$ (Comstock a. Königs, *B.* 19, 2851; 20, 2510).

Cinchonine-(β)-di-bromide $C_{19}H_{22}N_2Br_2O$. Formed at the same time as the preceding, from which it differs in crystallising in an anhydrous condition.

Cinchonine-di-bromide-sulphuric acid. Formed by several hours' standing at the ordinary temperature of a solution of cinchonine-di-bromide in 7–8 parts of conc. H_2SO_4. Crystalline solid. Sl. sol. cold water, v. sol. aqueous alkalis, an excess of which precipitates the alkaline salts of the acid. By heating with dilute HBr at c. 130° it is split up again into cinchonine-di-bromide and H_2SO_4 (Comstock a. Königs, *B.* 19, 2855).

Cinchonine-chloro-hydride $C_{19}H_{23}ClN_2O$. *Hydrochlorcinchonine.* [213°]. Formed by allowing a solution of cinchonine in fuming HCl (saturated at −17°) to stand at the ordinary temperature for several weeks. Colourless crystals (from alcohol). By boiling with alcoholic KOH it yields isocinchonine and a little cinchonine. The *hydrochloride* $C_{19}H_{23}ClN_2O,H_2Cl_2$ crystallises in prisms (Comstock a. Konigs, *B.* 20, 2519).

Cinchonine-bromo-hydride $C_{19}H_{23}BrN_2O$. *Hydrobromcinchonine.* '*Bromcinchonide*' of Skraup. Formed by the action of fuming HBr (saturated at −17°) upon cinchonine at the ordinary temperature or at 100°. Boiled with alcoholic KOH it gives a mixture of cinchonine and isocinchonine. — $C_{19}H_{23}BrN_2O,H_2Br_2$ (Comstock a. Königs, *B.* 20, 2520).

Cinchonine-chloride $C_{19}H_{21}N_2Cl$. [72°]. Formed by heating the hydrochloride of cinchonine with $POCl_3$ and PCl_5. Trimetric prisms. By boiling with alcoholic KOH it yields cinchene $C_{19}H_{20}N_2$ (Comstock a. Königs, *B.* 14, 1854; 17, 1984).

Dehydro-cinchonine $C_{19}H_{20}N_2O$. [203°]. Formed by heating cinchonine-di-bromide with alcoholic KOH. Colourless needles. Sublimable. V. sol. alcohol, acetone, and chloroform, m. sol. ether and hot benzene, v. sl. sol. ligroin and water. — B'HBr: colourless prisms. — B'HCl: very soluble long silky needles (Comstock a. Königs, *B.* 19, 2856).

Dehydro-cinchonine-bromo-hydride $C_{19}H_{21}BrN_2O$. *Hydrobromdehydrocinchonine. Bromo-cinchonine.* [c. 2[illegible]5°]. Crystalline. Formed by allowing a solution of dehydrocinchonine in very conc. HBr to stand for 8 days at the ordinary temperature (Comstock a. Königs, *B.* 20, 2524).

'**Dehydrocinchonine-chloride**' $C_{19}H_{19}N_2Cl$. [149°]. Formed by the action of PCl_5 upon dehydrocinchonine. Colourless crystals. V. sol. alcohol, ether, acetone, chloroform, and benzene, nearly insol. ligroïn. By boiling with alcoholic KOH it is converted into dehydrocinchene $C_{19}H_{18}N_2$ (Comstock a. Königs, *B.* 19, 2857).

Di-hydro-di-cinchonine $(C_{19}H_{23}N_2O)_2$. [258°]. Formed by treating an acid solution of cinchonine with sodium-amalgam or with zinc and H_2SO_4 (Zorn, *J. pr.* [2] 8, 293; Howard, *C. J.* 26, 1179; Skraup, *B.* 11, 312). Scales (from alcohol).— $B'H_2SO_4$.

Hydrocinchonine $C_{19}H_{24}N_2O$. Formed at the same time as the above. Amorphous. When Cl is passed into an aqueous solution of its chloride there is formed hexa-chloro-hydrocinchonine $C_{19}H_{18}Cl_6N_2O$ and tetra-chloro-dispoline $C_{11}H_7Cl_4N$. HNO_3 converts hydrocinchonine into amorphous tetra-nitro-hydrocinchonine $C_{19}H_{20}(NO_2)_4N_2O$.

Cinchonibine $C_{19}H_{22}N_2O$. [259°]. $[\alpha]_D = 176°$ (in alcohol); $= 220°$ (in HClAq). Insol. water and ether. Alkaline to litmus, but not to phenol-phthalein. — B'MeI. — $B'Me_2I_2$ 1½aq. — B'EtI.—$B'Et_2I_2$ (Jungfleisch a. Léger, *C. R.* 106, 1410).

Cinchonigine $C_{19}H_{22}N_2O$. [128°]. $[\alpha]_D = -60°$. The bases formed from cinchonine by heating with sulphuric acid can be separated by ether. From the ethereal extract HCl pps. cinchonigine hydrochloride and the mother-liquor on concentration, addition of soda and re-extraction with ether gives with HI cinchoniline hydro-iodide. The bases insoluble in ether are 4 in number, and are separated by weak alcohol, in which cinchonibine and cinchonifine are insoluble, while (α) and (β) oxycinchonine dissolve (Jungfleisch a. Leger, *C. R.* 106, 68, 357).

Properties.—Colourless prisms, volatile, distils under reduced pressure, sol. alcohol and dilute HCl. Sl. sol. water; v. sol. chloroform, benzene, and acetone; less sol. dry ether. Probably identical with the base obtained by Caventou a. Girard (*C. R.* 106, 71) by heating cinchonine with oxalic acid and H_2SO_4.

Salts.—B'HCl aq; [213°].—B'2HCl aq.—B'HBr aq.—B'HI aq.—B'2HI aq.—$B'_2C_2H_2O_4$; needles.—$B'C_4H_6O_6$ 3½aq.—B'MeI [253°]; colourless needles.— B'EtI aq [232°]; large prisms from alcohol.—B'EtBr aq.—$B'H_2PtCl_6$ aq (Jungfleisch a. Leger, *C. R.* 106, 357).

Cinchoniline $C_{19}H_{22}N_2O$. [130°]. $[\alpha]_D = +53{\cdot}22°$ in alcohol. Prepared as above. Rhombic prisms, dextrorotatory. Sl. sol. water, v. sol. most solvents. Its aqueous solution is turned blue by litmus and red by phenol-phthalein. Reduced in the cold by $KMnO_4$. Yields the same products as cinchonine on heating.

Salts.—B'HCl 3aq [226°]; v. sol. water $[\alpha]_D = +5°$.—$B'2HClPtCl_4$ aq; yellow prisms.—$B'2HClAuCl_3$ ½aq; prisms.—B'HBr 3aq; prisms, less soluble than the chloride.—B'HI aq; B'2HI; B'HCNS aq.

Methyl and ethyl compounds B'MeI [235°]; B'EtI; B'EtBr are all three v. sol. most solvents (Jungfleisch a. Leger, *C. R.* 106, 657).

Cinchotenine $C_{18}H_{20}N_2O_3$. [198°]. $[\alpha]_D = 135°$ in a 2 p.c. alcoholic solution. The chief product of the action of $KMnO_4$ on cinchonine dissolved in dilute H_2SO_4 (Skraup, *B.* 11, 311; *A.* 197, 376). Needles or plates (containing 3aq). Dextrorotatory. Not attacked by cold $KMnO_4$.—$B'H_2PtCl_6$; prisms.—$B'(HAuCl_4)_2$; needles.

Cinchotenicine $C_{18}H_{20}N_2O_3$. [153°]. The sulphate is formed by fusing cinchotenine sulphate

It is feebly dextrorotatory, and forms an amorphous platinochloride.

Cinchonicine $C_{19}H_{22}N_2O$. $(\alpha)_D = 46{\cdot}5°$ in a 2 p.c. solution in chloroform. Formed by heating the acid sulphate of cinchonine or cinchonidine (Pasteur, *C. R.* 37, 110; Hesse, *A.* 178, 253). Formed also by heating the tartrate or acid tartrate of cinchonine, and by heating cinchonine, cinchonidine, or cinchonine sulphate with glycerin (Howard, *C. J.* 25, 102; Hesse, *A.* 147, 242; 166, 277). Slightly yellowish viscid mass, which becomes a mobile liquid at 50°. V. sol. alcohol and ether. Its alcoholic solution tastes bitter and is alkaline to litmus. Cl and NH_3 give no green colour. Bleaching-powder gives a white pp. in a solution of its hydrochloride (difference from cinchonine and cinchonidine). Dextrorotatory.

Salts.—$B'HI$: prisms, m. sol. cold water.—$B'_4H_3Cl_3(PtCl_4)_2$4aq (?).—$B'H_2PtCl_6$ aq.—Oxalate $B'_2H_2C_2O_4$ 4aq: slender prisms.—Acid tartrate $B'C_4H_6O_6$ aq.

Apocinchonine $C_{19}H_{22}N_2O$. [209°]. $[\alpha]_D = 160°$ in a 1 p.c. alcoholic solution at 16° (Hesse, *A.* 205, 330; Oudemans, *R. T. C.* 1, 173). Formed, together with diapocinchonine, by heating cinchonine with HCl (S.G. 1·125) at 150°. The product is nearly neutralised with ammonia, alcohol is added, and the solution heated to boiling; excess of NH_3 now pps. apocinchonine. Prisms, sl. sol. ether, insol. water.

Salts.—The salts are dextrorotatory, for the neutral salt $[\alpha]_D$ varies from 180° to 215°; for the basic salts from 164° to 176°.—$B'HCl$2aq.—$B'H_2PtCl_6$ 2aq.—$B'HBr$ aq.—$B'HI$ aq.—$B'_2H_2SO_4$2aq (H.).—$B'_2H_2SO_4$3aq (O.).—$B'HClO_3$. $B'HClO_4$ aq. $B'_2H_2C_2O_4$ 2aq.

Acetyl derivative $C_{19}H_{21}AcN_2O$. $[\alpha]_D = 71°$ in a 2 p.c. alcoholic solution at 15°.—$B'H_2PtCl_6$ 2aq.

Apocinchonine chlorohydride $C_{19}H_{23}ClN_2O$. [197°]. $[\alpha]_D = 211°$ (Oudemans), –205° (Hesse) in a $\frac{1}{2}$ p.c. alcoholic solution at 16°. Formed by heating cinchonine or apocinchonine with saturated HClAq at 150° (Zorn, *J. pr.* [2] 8, 280; Hesse, *A.* 205, 348). Needles; v. sl. sol. water; sl. sol. ether and alcohol. Dextrorotatory. In the case of the neutral salts $[\alpha]_D$ varies from 215° to 229°; for the basic salts it lies between 192·5° and 195° (O.).—$B'H_2Cl_2$.—$B'HCl$ aq.—$B'H_2Br_2$.—$B'H_2PtCl_6$ 2aq.—$B'_2H_2SO_4$ 3aq.—$B'HNO_3$.—$B'HClO_3$.—$B'HClO_4$ *x*aq.—$B'H_2C_2O_4$ *x*aq.

Acetyl derivative $C_{19}H_{22}AcClN_2O$. $[\alpha]_D = 108°$ in a 2 p.c. alcoholic solution at 15°. Amorphous; v. sol. alcohol and ether.

Apocinchonine bromohydride $C_{19}H_{23}BrN_2O$. From cinchonine and conc. HBrAq at 100° (Skraup, *A.* 201, 324). Scales (from alcohol).—$B'H_2Br_2$: crystals.

Apocinchonicine $C_{19}H_{22}N_2O$. A resinous base, formed by heating apocinchonine acid sulphate at 140°. Inactive; v. sol. alcohol and ether.—$B'H_2PtCl_6$ 2aq.

Di-apocinchonine $(C_{19}H_{22}N_2O)_2$. $[\alpha]_D = 20°$ in a 2 p.c. alcoholic solution at 15°. Formed by the prolonged action of HCl on apocinchonine. Amorphous powder, v. sol. alcohol and ether. Dextrorotatory.—$B'H_2PtCl_6$ 4aq: amorphous.

Acetyl derivative $C_{38}H_{42}Ac_2N_4O_2$. $[\alpha]_D = 26°$ in a 2 p.c. alcoholic solution. Yellow amorphous mass.—$B'H_2PtCl_6$ 4aq; amorphous pp.—$B'(HAuCl_4)_4$ 2aq.

Iso-cinchonine $C_{19}H_{22}N_2O$. [127°]. Crystalline. Formed together with cinchonine by boiling cinchonine-chloro- or bromo-hydride ($C_{19}H_{23}ClN_2O$ or $C_{19}H_{23}BrN_2O$) with alcoholic KOH. V. e. sol. alcohol, ether, benzene, chloroform, acetic ether, and CS_2, sl. sol. ligroïn, nearly insol. water. It forms easily soluble salts. The zinc double chloride $C_{19}H_{22}N_2O, ZnCl_2, H_2Cl_2$ forms small needles (Comstock a. Königs, *B.* 20, 2521). A substance called isocinchonine has also been obtained by Hesse (*A.* 243, 149) among the products of the action of conc. H_2SO_4 on cinchonine.

CINCHOTENICINE *v.* CINCHONINE.

CINCHOTENIDINE *v.* CINCHONINE.

CINCHOTENINE *v.* CINCHONINE.

CINCHOTINE *v.* CINCHONA BASES.

CINCHOVATINE *v.* ARICINE.

CINENE $C_{10}H_{16}$. *Cynene.* (181°–182°). S.G. $\underline{16}$ ·854 (Wallach a. Brass, *A.* 225, 309).

Formation.—1. By passing HCl into boiling oleum cinæ (worm-seed oil) or cineol (*cf.* Volckel, *A.* 89, 358).—2. From cineol and BzCl.—3. From $C_{10}H_{18}I_2$ (got from cineol and HI) and aniline.—4. Among the products of the distillation of caoutchouc (when it is called caoutchin).—5. By heating isoprene at 260°.

Properties.—Oil, with pleasant odour of lemon.

Reactions.—1. *Bromine* added to its cold solution in alcohol or ether forms the tetrabromide $C_{10}H_{16}Br_4$ [125°].—2. Conc. H_2SO_4 converts it into cymene, giving off SO_2. P_2S_5 behaves similarly. (*V.* also TERPENES.)

Dihydrochloride $C_{10}H_{18}Cl_2$. [50°].

Dihydrobromide $C_{10}H_{18}Br_2$. [64°]. White silky plates. Formed by the action of HBr gas upon worm-seed oil. It is slowly decomposed on standing in contact with alcohol. On heating or by boiling with water or dilute alkalis it loses HBr giving cinene. It decomposes on keeping in the course of several weeks (Hell a. Ritter, *B.* 17, 2609).

Dihydroiodide $C_{10}H_{18}I_2$ [77°]. White felted needles. Formed by the action of gaseous HI upon worm-seed oil. It decomposes on keeping in the course of a few days, and quickly in contact with alcohol. By zinc-dust and water it is reduced to cynene-di-hydride $C_{10}H_{18}$ (Hell a. Ritter, *B.* 17, 2611).

Dihydride $C_{10}H_{18}$. (166°). V.D. = 5 (obs.). Colourless liquid, of ethereal odour. Formed by boiling cinene-di-hydrochloride or cinene-di-hydroiodide with zinc-dust and water (Hell a. Ritter, *B.* 17, 2612).

CINEOL $C_{10}H_{18}O$. (176°). S.G. $\underline{20}$ ·927. $\mu_D = 1{\cdot}458$. V.D. 5·12 (Wallach a. Brass, *A.* 225, 295; 245, 195; Gladstone, *C. J.* 49, 621). The chief constituent of oleum cinæ and of oil of cajeput; occurs also in oil of rosemary (Weber, 238, 89). Liquid, smelling like camphor, inactive. Boiling HNO_3 (S.G. 1·15) forms oxalic acid only.

Reactions.—1. HCl passed into its solution in ligroin forms crystals of $(C_{10}H_{18}O)_2HCl$, a body which is decomposed by water, reproducing cineol, but when heated alone produces cinene: $(C_{10}H_{18}O)_2HCl = 2H_2O + HCl + C_{10}H_{16}$.—2. HI passed into oleum cinæ ultimately converts it into a crystalline mass of $C_{10}H_{18}I_2$. Crystallised from light petroleum, this forms trimetric tablets: *a*:*b*:*c* = ·7588:1: ·7074 [78·5°]. Alcoholic KOH converts it into cinene.—3. Excess of *Bromine* added at 0° to a solution of cineol in light petroleum forms red crystals of $C_{10}H_{18}OBr_2$. These crystals decompose on keeping, forming cinene tetrabromide and water: $2C_{10}H_{18}OBr_2 = C_{10}H_{16}Br_4 + 2H_2O + C_{10}H_{16}$. When a smaller quantity of Br is added to a solution of cineol in light petroleum, needles of $(C_{10}H_{18}O)_2Br_2$ are formed (Wallach, *A.* 230, 228).—4. Cineol also combines with *iodine* forming crystals of $(C_{10}H_{18}O)_2I_2$.

Constitution.—Sodium, PCl_5 in the cold, and BzCl at 120° do not act on cineol. Hence it appears not to contain hydroxyl. At 150° BzCl removes H_2O. Hydroxylamine and phenylhydrazine do not act on cineol. Brühl (*B.* 21, 461) gives cineol the constitution  since it is optically inactive and on passing HCl through it it is converted into optically inactive .

Isomerides of Cineol are described under BORNEOL; *v.* also CAMPHORS, vol. i. p. 672. The matter will be less complicated if we can assume the existence of only two compounds of the formula $C_{10}H_{17}OH$ with rotatory power +38° and −38° respectively, the others being mixtures of these in varying proportions. Thus the lævorotatory camphols ($[\alpha]_D = -38°$) derived from *Blumea balsamifera* (N'gai camphor and also, from the same tree, Bang Phiên), Martico camphor, the camphor from oil of valerian, and that from madder, are in all respects identical (Haller, *C. R.* 103, 64, 151). Ordinary borneol is a cineol of rotatory power +38°. Camphol from amber appears to be partly of the racemic character (*i.e.* an inactive compound of camphols of rotatory power +38° and −38°) and partly of dextrorotatory borneol (Haller, *C. R.* 104, 66). By dissolving a camphol (50 g.) in toluene (150 g.), heating with sodium (6 g.) and passing in cyanogen a product is got whence water extracts a camphyl carbamate $C_{10}H_{17}.O.CO.NH_2$. The product derived from dextrorotatory camphol is described (vol. i. p. 523) as bornyl carbamate. It is dextrorotatory and forms dextro-hemihedral crystals. Lævorotatory camphol forms an isomeride [127°] which is lævorotatory ($[\alpha]_D = -29·90°$), and crystallises in lævo-hemihedral forms. In each preparation, camphyl carbonate $(C_{10}H_{17})_2CO_3$ is a by-product; the carbonate from borneol is dextrorotatory while that from lævorotatory camphol is lævorotatory. Both melt at 215° (Haller, *C. R.* 98, 578).

CINNAMEIN *v. Benzyl ether* of CINNAMIC ACID.

CINNAMENE *v.* STYRENE.

CINNAMENYL COMPOUNDS $C_6H_5.CH:CH-X$ *v.* STYRYL COMPOUNDS.

CINNAMENYL-AMIDO-PHENYL-MERCAPTAN $C_{15}H_{11}NS$ *i.e.*

$C_6H_4\langle{}^{N}_{S}\rangle C.CH:CH.C_6H_5$ [111°]. Prepared by the action of cinnamic acid on amido-phenyl-mercaptan (Hofmann, *B.* 13, 1235). Colourless prisms. Sol. alcohol. Weak base. On fusion with KOH it is split up into cinnamic acid (which is further converted into benzoic acid) and amido-phenyl-mercaptan.

Salts.—B'HCl: unstable salt.—$(B'HCl)_2PtCl_4$: yellow needles.

CINNAMIC ACID $C_9H_8O_2$ *i.e.* $C_6H_5.CH:CH.CO_2H$. *Phenyl-acrylic acid. Benzylidene acetic acid.* Mol. w. 148. [133°] (Kraut, *A.* 133, 93; 147, 112). (300°). S.G. $\frac{4}{}$ 1·248 (Schröder, *B.* 12, 1612). S. ·03 at 17°; S. (alcohol) 2·3 at 20°; S. ($CHCl_3$) 6 at 15°; S. (CS_2) ·9 at 15°. *Electrical conductivity*: Ostwald, *J. pr.* [2] 32, 365.

Occurrence.—1. In oil of cinnamon (Dumas a. Péligot, *A. Ch.* 57, 311; Herzog, *Ar. Ph.* 17, 72; 20, 159).—2. In liquid storax which contains styrene, cinnamic acid, and styryl cinnamate (styracin) (E. Simon, *A.* 31, 265; D. Howard, *C. J.* 13, 135; Beilstein a. Kuhlberg, *Z.* [2] 7, 489).—3. In balsam of Peru, which contains benzyl cinnamate, benzoic acid, and cinnamic acid (E. Kopp, *Compt. chim.* 1847, 198; 1849, 146; 1850, 140; Kraut, *B.* 2, 180; Delafontaine, *Z.* 1869, 156).—4. In balsam of Tolu, which is similar in composition to that of Peru (Frémy, *A.* 30, 338; Deville, *A.* 44, 304; E. Kopp, *A.* 60, 269; Busse, *B.* 9, 830).—5. In gum benzoin from Sumatra (Kolbe a. Lautemann, *A.* 119, 136). 6. In the leaves and stalks of *Globularia vulgaris* (Heckel a. Schlagdenhauffen, *A. Ch.* [5] 28, 69). 7. In the leaves of *Eukianthus japonicus* (Eykman, *R. T. C.* 5, 297).

Formation.—1. By heating benzoic aldehyde with AcCl for 24 hrs. at 125° (Bertagnini, *Cimento*, 4, 46; *A.* 100, 126).—2. By heating benzoic aldehyde with HOAc and $ZnCl_2$ at 160° (Schiff, *B.* 3, 412; *Z.* [2] 6, 700).—3. By heating benzoic aldehyde (2 pts.), Ac_2O (3 pts.), and NaOAc (1 pt.) at 145° (Perkin, *C. J.* 31, 389; Slocum, *A.* 227, 58). This reaction, commonly known as Perkin's synthesis, is discussed under ALDEHYDES (vol. i. p. 108).—4. By the action of benzoic aldehyde on sodium malonate in presence of Ac_2O in the cold, CO_2 being evolved: $Ph.CHO + CH_2(CO_2H)_2 = PhCH:C(CO_2H)_2 + H_2O = PhCH:CH.CO_2H + CO_2 + H_2O$ (Stuart, *C. J.* 43, 404).—5. By heating benzoic aldehyde with malonic acid at 130° (Michael, *Am.* 5, 205).—6. By the action of KOH on benzyl-chloro-malonic ether (Conrad, *B.* 13, 2160).

Properties.—Monoclinic prisms (from alcohol) (Schabus, *Sitz. W.* 1850, ii. 206). When quickly distilled it is but little decomposed, but when slowly distilled it splits up into CO_2 and styrene (Howard, *C. J.* 13, 135). Volatile with steam. V. sl. sol. water, v. sol. alcohol, v. e. sol. ether; v. sl. sol. cold ligroïn.

Reactions.—1. Distillation with *lime* gives styrene and benzene.—2. *Potash-fusion* gives potassium acetate and benzoate (Chiozza, *A. Ch.* [3] 39, 439; Kraut, *A.* 147, 113). Fusion with NaOH gives CO_2 and benzene (50 p.c. of theoretical) (Barth a. Schreder, *B.* 12, 1257).—3. SO_3 forms sulphobenzoic acid. Boiling with H_2SO_4

diluted with 1 to 1¼ vols. water forms an oil, consisting of distyrene $C_{16}H_{16}$ and distyrenic acid $C_{17}H_{16}O_2$.—4. Conc. HNO_3 gives nitro-benzoic acid, but a more dilute acid gives benzoic aldehyde.—5. Boiling with PbO_2 in aqueous solution forms benzoic aldehyde and lead benzoate (Stenhouse, *A.* 55, 1; 57, 79).—6. *Chromic mixture* also forms benzoic aldehyde (Simon). $KMnO_4$ in feebly alkaline solution acts in the same way (A. Bauer, *A.* 220, 37). $KMnO_4$ in very dilute neutral solution at 0° oxidises cinnamic acid to $PhCH(OH).CH(OH).CO_2H$ (Fittig, *B.* 21, 919).—7. Br gives di-bromo-phenyl-propionic acid (A. Schmitt, *A.* 127, 319).—8. Fuming HBr gives bromo-phenyl-propionic acid. HI acts in a similar way.—9. *Sodium amalgam* reduces it to phenyl-propionic acid (Erlenmeyer, *A.* 137, 327). Conc. HIAq does the same (Popoff, *Z.* [2] 1, 111). 10. HClO gives chloro-oxy-phenyl-propionic acid (Glaser, *A.* 147, 78; *Z.* [2] 3, 65; 4, 131).—11. Boiling aqueous K_2SO_3 gives sulpho-phenyl-propionic acid.—12. Chlorine acts on aqueous sodic cinnamate in two ways, viz.:

$$\begin{aligned}&(1)\ Ph.CH{:}CH.CO_2Na + Cl_2\\ &= Ph.CHCl.CHCl.CO_2Na\\ &= \underbrace{Ph.CH.CHCl.CO.O}_{} + NaCl\\ &= Ph.CH{:}CHCl + CO_2 + NaCl\\ &(2)\ Ph.CH{:}CH.CO_2Na + Cl_2 + H_2O\\ &= Ph.CH{:}CH.CO_2H + HClO + NaCl\\ &= Ph.CH(OH).CHCl.CO_2H + NaCl\end{aligned}$$

producing ω-chloro-styrene and chloro-oxy-phenyl-propionic acid (Erlenmeyer a. Lipp, *A.* 219, 184).—13. *Diphenylamine* and $ZnCl_2$ at 250° form phenyl-acridine (Bernthsen, *B.* 20, 1552).—14. *m-Oxy-benzoic acid* and H_2SO_4 form a body $C_{16}H_8O_3$ or

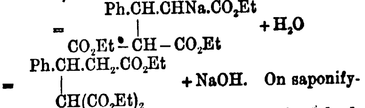
$$C_6H_4\!<\!\begin{array}{l}C\!/\!\!/\!CH.CO\\ CO\end{array}\!\!>\!C_6H_3\!>\!O$$

[260°] (Kostanecki, *B.* 20, 3137). It forms a diacetyl derivative [260°]. 15. *s-Di-oxy-benzoic acid* and H_2SO_4 give the oxy-derivative of the preceding [325°] which forms a crystalline acetyl derivative $C_{16}H_7AcO_4$ [255°] (K.).—16. Gallic acid and H_2SO_4 at 50° form, in the same way, 'styrogallol,' a dioxy-derivative of the above $C_{16}H_8O_5$, which crystallises in minute yellow needles, melting above 350° (Jacobsen a. Julius, *B.* 20, 2588). Its di-acetyl derivative melts at 260°.

Salts (Herzog, *J. pr.* 29, 51; E. Kopp, *C. R.* 53, 634).—NH_4A' ½aq: sl. sol. cold water.—KA' ½aq: monoclinic crystals; v. sol. water, m. sol. alcohol.—NaA' ½aq: needles (from dilute NaOHAq).—$NaHA'_2$ (Perkin, *C. J.* 31, 388).—AgA': curdy pp. insol. boiling water.—BaA'_2 aq (Herzog).—BaA'_2 2aq: pearly plates (Kopp).—BaA'_2 3aq: iridescent leaflets or striated prisms (Rebuffat, *G.* 11, 160).—CaA'_2 2aq (H.; R.).—CaA'_2 3aq (K.). S. ·16 at 17°.—SrA'_2 4aq: nacreous needles.—MgA'_2 3aq: white needles.—$CuA'_2(CuO_2H_2)x$: greenish-blue pp.—PbA'_2: crystalline powder or flattened needles.—CdA'_2 2aq.—MnA'_2 2aq.—ZnA'_2 2aq: prismatic needles (from hot water).

Methyl ether MeA'. [34°]. (263° i.V.). S.G. $\frac{36}{0}$ 1·0415. Formed by the action of the ethyl ether on methyl alcohol in presence of NaOMe (Purdie, *C. J.* 51, 628; *cf.* E. Kopp, *C. R.* 21, 1376; Anschütz a. Kinnicutt, *B.* 11, 1220; Weger, *A.* 221, 74). With Br it forms $C_6H_5.CHBr.CHBr.CO_2Me$ [117°].

Ethyl ether EtA'. [12°] (Friedländer, *A.* 221, 75). (268°) at 741 mm. (Brühl, *A.* 235, 19). (271° i. V.)(A. a. K.). S.G. $\frac{20}{4}$ 1·0490. μ_D 1·560 (B.). *Preparation.*—Cinnamic acid (500 g.) is dissolved in dry alcohol (1 litre) and HCl is passed in to saturation. After 3 hrs. the product is poured into ice-cold water. The oil is washed, dissolved in ether, and shaken with aqueous sodic carbonate, dried over $CaCl_2$, and the ether evaporated (Perkin, jun., *C. J.* 45, 172; *cf.* Herzog, *Ar. Ph.* [2] 17, 72; Marchand, *A.* 32, 269; E. Kopp, *J. pr. Pharm.* [3] 11, 72; Plantamour, *A.* 30, 345). *Reactions.*—1. With *bromine* it forms $C_6H_5.CHBr.CHBr.CO_2Et$ [69°].—2. *Sodium-aceto-acetic ether* in presence of alcohol at 100° forms an acid $C_{15}H_{16}O_4$ [140°]. Its silver salt, AgA', forms radiating prisms, insol. water (Michael, *J. pr.* [2] 35, 354).—3. With *sodium malonic ether* at 100° in presence of alcohol it forms an oil $C_{18}H_{24}O_6$ (305°–310°) or (215° at 15 mm.). $Ph.CH{:}CH.CO_2Et + NaHC(CO_2Et)_2$



$$= \begin{array}{l}Ph.CH.CHNa.CO_2Et\\ \quad\quad |\\ CO_2Et-CH-CO_2Et\end{array} + H_2O = \begin{array}{l}Ph.CH.CH_2.CO_2Et\\ \quad |\\ CH(CO_2Et)_2\end{array} + NaOH.$$

On saponifying and heating the resulting acid CO_2 is evolved, and there results phenyl-glutaric acid

$$\begin{array}{l}Ph.CH.CH_2.CO_2H\\ |\\ CH.CO_2H\end{array}$$

[138°]. Its silver salt, AgA', is amorphous (Michael, *J. pr.* [2] 35, 349; *Am.* 9, 118).

n-Propyl ether PrA'. (283°–284° i.V.) (A. a. K.). S.G. $\frac{0}{0}$ 1·0435 (Weger, *A.* 221, 76).

Benzyl ether $C_6H_5.CH{:}CH.CO.OCH_2C_6H_5$. *Cinnameïn.* [39°]. Discovered by Plantamour (*A.* 27, 329; 30, 341) in balsam of Peru (Frémy, *A. Ch.* 70, 184; E. Kopp, *Compt. chim.* 1850, 140; Scharling, *A.* 74, 230; 97, 184; Kraut, *A.* 107, 208; Grimaux, *Z.* [2] 5, 157). Formed also by boiling dry sodium cinnamate with alcohol and benzyl chloride for some hours. Short prisms (from alcohol).

Phenyl ether $C_6H_5.C_2H_2.CO_2C_6H_5$: [73°]; (206°) at 15 mm. Formed by the action of cinnamoyl chloride upon phenol. By slow distillation it loses carbonic acid, giving stilbene $C_6H_5.C_2H_2.C_6H_5$ (Anschütz, *B.* 18, 1945; *C. J.* 47, 898).

p-Tolyl ether $C_6H_5.C_2H_2.CO_2C_7H_7$: [101°]; (230°) at 15 mm. (A.). By slow distillation it yields *s*-phenyl-tolyl-ethylene (A.).

Phenylpropyl ether $C_6H_5.C_2H_2.CO_2.CH_2.CH_2.CH_2.C_6H_5$. Occurs in storax (Miller, *A.* 189, 353), and is also formed by treating styracin bromide with zinc and H_2SO_4.

Thymyl ether $C_6H_5.C_2H_2.CO_2C_{10}H_{13}$: [70°]; (240°) at 15 mm. (A.).

(β)-Naphthyl ether $C_6H_5.C_2H_2.CO_2C_{10}H_7$: [102°]. By distillation CO_2 is split off with formation of *s*-phenyl-naphthyl-ethylene (A.).

Cinnamyl ether $C_6H_5.CH{:}CH.CO.O.CH_2.CH{:}CH.C_6H_5$. *Styracin.* [44°]. S. (ether) 33; S. (alcohol of S.G. ·825) 33 at 78°; 5 at 15°. Occurs in liquid storax (Bonastre, *J. Ph.* 1831, 338; E. Simon, *A.* 31, 265; E. Kopp, *Compt. chim.* 1850, 140; Toel, *A.* 70, 1; Strecker, *A.* 70, 10; 74, 112; Wolff, *A.* 75, 297; Plantamour, *A.* 27, 329; 30, 341; Gössmann, *A.* 99, 376; Scharling, *A.* 97, 90, 174; W. v. Miller, *N. Rep. Pharm.* 24, 1; *A.* 188, 200; 189, 344). Needles or prisms (from alcohol). Chlorine forms a viscid tetra-chloro- derivative $C_{18}H_{12}Cl_4O_2$. Br forms $C_{18}H_{16}Br_2O_2$ [151°] and $C_{18}H_{16}Br_4O_2$.

Chloride $C_6H_5.CH:CH.CO.Cl.$ [36°]. (170°) at 58 mm. Prisms (Cahours, *A. Ch.* [3] 23, 341; Rostoski, *A.* 178, 214 (Claisen a. Antweiler, *B.* 13, 2123).

Cyanide $C_6H_5.CH:CH.CO.CN.$ [115°]. Prisms. Sol. ether, $CHCl_3$, C_6H_6, and CS_2; v. sl. sol. water. Prepared from the chloride by the action of silver cyanide. On saponification it gives cinnamoyl-formic acid.

Anhydride $(C_6H_5.CH:CH.CO)_2O.$ [127°]. (Gerhardt, *A. Ch.* [3] 37, 285; *A.* 87, 76). Crystalline.

Amide $C_6H_5.CH:CH.CO.NH_2.$ [142°]. (v. Rossum, *Z.* 1866, 362). — $(C_6H_5.C_2H_2.CO.NH)_2Hg.$

Anilide $C_6H_5.CH:CH.CO.NPhH$ (Cahours, *A.* 70, 43). Slender needles.

Diphenylamide $C_6H_5.CH:CH.CO.NPh_2.$ [153°] (Bernthsen, *B.* 20, 1554). Needles.

Nitrile $C_6H_5.CH:CH.CN.$ [11°]. (255°). From the amide and PCl_5. Also from cinnamic acid and lead sulphocyanide at 190° (Kruss, *B.* 17, 1768).

Cinnamic acid dibromide *v.* DI-BROMO-PHENYL-PROPIONIC ACID.

Cinnamic acid hydrobromide *v.* BROMO-PHENYL-PROPIONIC ACID.

Cinnamic-acid-di-nitrite $C_6H_5.C_2H_2(NO_2)_2.CO_2H.$ *Phenyl-di-nitro-propionic acid.* Colourless crystals. Formed by direct combination of cinnamic acid with N_2O_4. Very unstable. By treatment with water or alcohol it evolves CO_2 and yields phenyl-nitro-ethylene $C_6H_5.CH:CH(NO_2)$ (Gabriel, *B.* 18, 2438).

p-**Aldehydo-cinnamic acid** $C_6H_4(CHO)(CH:CH.CO_2H).$ [247°]. From terephthalic aldehyde, NaOAc, and Ac_2O by Perkin's reaction (Löw, *A.* 231, 374). Flat prisms or needles. Sl. sol. hot water, ether, or chloroform, more sol. glacial acetic acid. When sublimed it forms large plates. Salt.—AgA.

Ethyl ether EtA'. Reduces ammoniacal $AgNO_3$. Gives by Perkin's reaction

$$C_6H_4(CH:CH.CO_2H)(CH:CH.CO_2Et)$$

(*v.* PHENYLENE-DI-ACRYLIC ACID). *Reactions.* — 1. Reduces ammoniacal $AgNO_3$ with difficulty.— 2. Does not react with NaOAc and Ac_2O.—3. On nitration gives nitro-aldehydo-cinnamic acid (*q. v.*).

Di-bromide $C_6H_4(CHO).CHBr.CHBr.CO_2H.$ [176°] (with decomposition). Prisms (from methyl alcohol). Insol. water; v. sol. ether, chloroform, and alcohol.

p-**Carboxy-cinnamic acid** $C_6H_4(CO_2H)(CH:CH.CO_2H)$ [1:4]. Got by saponifying its ether. Powder, will not melt, but may be sublimed. Nearly insoluble in solvents. Does not combine with bromine in the cold. Forms a nitro- derivative.

Dibromide $C_6H_4(CO_2H)(CHBr.CHBr.CO_2H).$ *Di-bromo-carboxy-phenyl-propionic acid.* Formed at 100°. Will not melt. Sol. methyl alcohol, from which it may be crystallised.

Mono-ethyl ether $C_6H_4(CO_2Et)(CH:CH.CO_2H)$ [220°]. From *p*-aldehydo-terephthalic ether, NaOAc, and Ac_2O by Perkin's reaction (Löw, *A.* 231, 369). Prisms (from ether).

Other derivatives of cinnamic acid are described as AMIDO-, BROMO-, CHLORO-, HYDRAZIDO-, NITRO-, SULPHIDO-, SULPHYDRO-, and SULPHO-CINNAMIC ACID. Oxy-cinnamic acid is described as COUMARIC ACID.

CINNAMIC ALDEHYDE C_9H_8O *i.e.* $C_6H_5.C_2H_2.CHO.$ Mol. w. 132. (129°). S.G. $\frac{20}{4}$ 1·0497 (Brühl, *A.* 235, 18). $\mu_D = 1·619.$ $\mu_\gamma = 1·683.$

Occurrence.—In oil of cassia and oil of cinnamon, whence it may be extracted by shaking with $NaHSO_3$ and distilling the resulting crystalline compound with aqueous Na_2CO_3 (Perkin, *C. J.* 31, 403; *cf.* Mulder, *A.* 34, 147; Bertagnini, *A.* 85, 271).

Formation.—1. By oxidising cinnamyl alcohol with the aid of platinum black (Strecker, *A.* 93, 370).—2. By distilling calcium formate with calcium cinnamate (Piria, *A.* 100, 105).

Preparation.—A mixture of benzoic aldehyde (10 pts.), acetic aldehyde (15 pts.), 10 pts. of 10 p.c. aqueous NaOH, and 900 pts. of water is allowed to stand for 8 or 10 days with frequent shaking at about 30°, the cinnamic aldehyde being finally extracted with ether (Chiozza, *A.* 97, 350; Peine, *B.* 17, 2109).

Properties.—Oil. Forms crystalline compounds with HCl, HNO_3, $NaHSO_3$, $KHSO_3$, and NH_4HSO_3 (Dumas a. Péligot, *A.* 14, 65).

Reactions.—With alcoholic NH_3 it gives hydrocinnamide $C_{27}H_{24}N_2$ [106°]. With HCN it yields the nitrile of *a*-oxy-phenyl-crotonic acid. With resorcin and dilute HCl it gives a resin in the cold (Michael a. Ryder, *Am.* 9, 134). HCl passed into a mixture of cinnamic aldehyde with phenyl mercaptan forms $C_6H_5C_2H_2CH(SPh)_2$ [81°] (Baumann, *B.* 18, 885). With carbamic ether it forms $Ph.C_2H_2.CH(NH.CO_2Et)_2$ [135°-143°] (Bischoff, *B.* 7, 1079).

Phenyl hydrazide $C_6H_5.C_2H_2.CH:N_2HC_6H_5$: [168°], yellow plates (Fischer, *B.* 17, 575).

Anilide $C_6H_5.C_2H_2.CH:NC_6H_5$: [109°], yellow glistening plates. Very stable towards HCl. Forms crystallisable salts with acids (Doebner a. Miller, *B.* 16, 1665; Peine, *B.* 17, 2109).

Di-methyl-amido-anilide $C_6H_5.C_2H_2.CH:N.C_6H_4(NMe_2)$: [141°]; yellow needles; sol. alcohol, sl. sol. cold ether (Nuth, *B.* 18, 574).

Ethylene-di-amide $(C_6H_5.C_2H_2.CH:N)_2C_2H_4$: [110°]; tables, m. sol. ether (Mason, *B.* 20, 267).

Di-bromide *v.* *aβ*-DI-BROMO-PHENYL-PROPIONIC ALDEHYDE.

CINNAMIC ALDOXIM $C_6H_5.CH:CH.CH:NOH.$ *Phenyl-acrylic aldoxim.* [136°]. Fine silky needles. V. sol. alcohol, ether, acids, and alkalis, nearly insol. cold water and ligroïn.

Benzoyl derivative $C_6H_5.C_2H_2.CH:NOBz.$ [125°]. White needles; sl. sol. cold alcohol and benzene, insol. water and ligroïn (Bornemann, *B.* 19, 1512).

CINNAMIC-CARBOXYLIC ACID *v. Carboxy-*CINNAMIC ACID.

CINNAMIDOXIM $C_9H_{10}N_2O$ *i.e.* $C_6H_5.CH:CH.C(NOH)NH_2$. *Phenyl-allenyl-amidoxim.* [93°]. Formed by direct combination of cinnamonitrile with hydroxylamine. Rod-like prisms. Sol. hot, less sol. cold water, v. sol. alcohol, ether, and benzene, sl. sol. ligroïn. Decomposed by long boiling with water.

Salts.— B'HCl: [155°], flat concentric prisms.—$B'_2H_2Cl_2PtCl_4$: concentric needles, sol. alcohol.

Methyl ether $C_8H_7.C(NH_2)NOMe$: [98°]; prisms; volatile with steam; v. sol. alcohol, ether, &c., nearly insol. cold water, more readily in hot.

Ethyl ether $C_8H_7.C(NH_2)NOEt$: [83°]; like the preceding.

Benzoyl derivative $C_8H_7.C(NH_2)NOBz$: [160°]; fine needles; v. sol. alcohol, more sparingly sol. benzene, chloroform, and ether, insol. cold water. On boiling with water it loses 1 mol. H_2O, giving phenyl-allenyl-azoxim-benzenyl (Wolff, *B.* 19, 1507).

CINNAMO-LACTONE *v.* COUMARIN.

CINNAMONE *v.* DI-BENZYLIDENE-ACETONE.

CINNAMOYL-ACETO-ACETIC ETHER $C_{15}H_{16}O_4$ *i.e.* $Ph.CH:CH.CO.CHAc.CO_2Et$. [40°]. From sodium aceto-acetic ether and cinnamoyl chloride (Fischer a. Kuzel, *B.* 16, 166). Crystalline grains (from ligroin).

α-CINNAMOYL-BUTYRIC ETHER *v. Benzylidene-ethyl-*ACETO-ACETIC ETHER, vol. i. p. 24.

CINNAMOYL-FORMIC ACID *v.* STYRYL-GLYOXYLIC ACID.

CINNAMYL ALCOHOL $C_9H_{10}O$ *i.e.* $C_6H_5.CH:CH.CH_2OH$. *Styrone.* Mol. w. 134. [33°]. (254°) at 747 mm. S.G. $\frac{20}{4}$ 1·0440. μ_D 1·582 at 20° (Brühl, *A.* 235, 16). R_∞ 69 7 (in a 9 p.c. alcoholic solution) (Kanonnikoff; Nasini a. Bernheimer, *G.* 14, 153). Obtained by distilling styracin (cinnamyl cinnamate) with aqueous potash (Simon, *A.* 31, 274; Ramdohr, *Z. Pharm.* 1858, 113; *J.* 1858, 446; Tol, *A.* 70, 3). Long thin needles, smelling like hyacinths. Sl. sol. cold water, v. e. sol. alcohol and ether.

Reactions.—1. *Oxidised* by air and platinum black to cinnamic aldehyde; and by chromic acid mixture to cinnamic acid and benzoic aldehyde.—2. Boiling with aqueous KOH and PbO_2 gives benzoic aldehyde.—3. Reduced by *sodium amalgam* in presence of much water to phenyl-propyl alcohol (Rugheimer, *A.* 172, 122). Reduced by (15 p.c.) sodium amalgam by heating with a little water for 3 days at 100° it forms styrene C_8H_8 and methyl alcohol, as follows:

$$PhCH:CH.CH_2OH + H_2 = Ph.CH:CH_2 + CH_3OH$$

(Hatton a. Hodgkinson, *C. J.* 39, 319).—4. Aqueous HI (S.G. 1·96) at 190° gives toluene and allyl-benzene (Tiemann, *B.* 11, 671).—5. Fuming H_2SO_4 forms $C_9H_{11}SO_3H$ (?) (Jacobsen, *A.* 146, 90).—6. B_2O_3 forms cinnamyl oxide $(C_9H_9)_2O$, a heavy oil.

Acetyl derivative C_9H_9OAc. (245°).

CINNAMYLAMINE $C_9H_{11}N$ *i.e.* $C_6H_5.CH:CH.CH_2.NH_2$. (100°). From cinnamyl chloride and alcoholic NH_3 at 100° (Ramdohr, *Z. Pharm.* 1858, 113; *J.* 1858, 448). According to Malbot (*C. R.* 105, 574) the chief product is di-cinnamyl-amine.—B'HCl: stellate groups of crystals.—$B'_2H_2PtCl_6$: sl. sol. cold water.

CINNAMYL CHLORIDE C_9H_9Cl *i.e.* $C_6H_5.CH:CH.CH_2Cl$. A liquid, obtained by passing HCl into cinnamyl alcohol. NaOEt converts it into oily C_9H_9OEt (Ramdohr, *Z. Pharm.* 1858, 113; *J.* 1858, 448). K_2S forms oily $(C_9H_9)_2S$.

CINNAMYLIDENE - DIACETONAMINE *v.* vol. i. p. 28.

CINNAMYLIDENE - DI - THIO - GLYCOLLIC ACID $Ph.CH:CH.CH:(SCH_2CO_2H)_2$. [143°]. Formed by the action of cinnamic aldehyde on thio-glycollic acid (Bongartz, *B.* 21, 481). White plates (from hot water). By the action of zinc-dust in an alkaline solution cinnamyl thio-glycollic acid is formed.

CINNAMYL IODIDE C_9H_9I. From cinnamyl alcohol and PI_2. Oil. Converted by alcoholic KCy into oily C_9H_9Cy.

DI-CINNAMYL KETONE *v.* DI-BENZYLIDENE-ACETONE.

CINNAMYL-METHYL KETONE *v.* BENZYLIDENE ACETONE.

CINNAMYL-PHENYL-KETONE *v.* PHENYL-CINNAMYL-KETONE.

CINNAMYL-THIO-GLYCOLLIC ACID $Ph.CH:CH.CH_2.S.CH_2.CO_2H$. [77°]. The compound obtained by the action of cinnamic aldehyde on thioglycollic acid when treated with zinc-dust in an alkaline solution yields this substance (Bongartz, *B.* 21, 481). White plates (from dilute alcohol).

CINNOLINE $C_8H_6N_2$ *i.e.*  $C_6H_4\left\langle\begin{array}{l}CH:CH\\ \quad\;\;|\\ N:N\end{array}\right.$. This base has not been isolated. The first of its derivatives prepared was oxy-cinnoline carboxylic acid  $C_6H_4\left\langle\begin{array}{l}C(OH):C.CO_2H\\ \qquad\quad|\\ N\;=\;N\end{array}\right.$ obtained by warming *o*-diazo-phenyl-propiolic acid with water (Richter, *B.* 16, 677; *v.* also Widman, *B.* 17, 722).

CINNYL. A name sometimes applied to the radicle cinnamyl $Ph.CH:CH.CH_2$.

CIRCULAR POLARISATION *v.* PHYSICAL METHODS.

CITRACETIC ACID $C_6H_6O_6$. An acid said to be formed, together with aceconitic acid, by treating bromo-acetic ether with sodium (Baeyer, *A.* 135, 306).—$Ba_3A'''_2 2aq$: gummy.—$Pb_3A'''_2 2aq$.

CITRA-DI-BROMO-PYROTARTARIC ACID *v.* DI-BROMO-PYROTARTARIC ACID.

CITRA - CHLORO - PYROTARTARIC ACID *v.* CHLORO-PYROTARTARIC ACID.

CITRACONANIL *v. Phenylimide of* CITRACONIC ACID.

CITRACONIC ACID $C_5H_6O_4$. Mol. w. 130. [80°]. S.G. 1·6. S. 238. R_∞ 44·68 (in a 7 p.c. aqueous solution) (Kanonnikoff, *J. pr.* [2] 32, 497). H.C. 477867 (Louguinine, *C. R.* 106, 1291). *Heat of solution*: 2793 (Gal a. Werner, *Bl.* [2] 47, 159). *Heat of neutralisation*: 27082 (G. a. W.).

Formation.—1. The anhydride is the chief portion of the distillate obtained by heating citric acid. It rapidly combines with water (Lassaigne, *A. Ch.* [2] 21, 100; Robiquet, *A. Ch.* 75, 78; Liebig, *A.* 26, 119, 152; Gottlieb, *A.* 77, 265; Baup, *A. Ch.* [3] 33, 192; Kämmerer, *A.* 170, 191; Wilm, *A.* 141, 28).—2. By the distillation of itaconic acid (Crasso, *A.* 34, 68), of lactic acid (Engelhardt, *A.* 70, 246), of citramalic acid (Carius, *A.* 129, 160), and of oxypyrotartaric acid (Demarçay, *C. R.* 82, 1337).

Properties.—Monoclinic four-sided prisms. Deliquescent. V. sol. water, alcohol, and ether. Volatile with steam. *By* dry distillation it is partially resolved into its anhydride.

Reactions.—1. *Sodium amalgam* in presence of water reduces it to pyrotartaric acid.—2. *Bromine* unites with it in the cold, forming citra-di-bromo-pyrotartaric acid (Kekulé, *J.* 1862, 818).—3. Fuming *hydric bromide* unites with it even in the cold, forming citra-bromo-pyrotartaric acid.—4. *Electrolysis* of the potassium salt forms allylene $CH_3.C:CH$.—5. *Water* at 120° changes it to the isomeric itaconic acid.—6. Boiling dilute HNO_3 forms mesaconic acid.—7. *Chlorine* acting on sodium citraconate in aqueous solution forms chloro-citramalic, chloro-methacrylic, and tri-chloro-isobutyric acids and tri-chloro-acetone (Gottlieb, *J. pr.* [2] 12, 1; Morawski, *J. pr.* [2] 12, 369).

Salts.—NH_4HA''.—CaA''aq.—$CaH_2A''_2$ 3aq. CaA'' 5aq (Kämmerer, *A.* 148, 326). — $SrH_2A''_2$ 3aq. — $BaH_2A''_2$ aq: silky needles. — BaA'' 2⅓aq (Kämmerer, *A.* 170, 191; Petri, *B.* 14, 1634). — $PbH_2A''_2$. — PbA''. — PbA'' 2aq. — $PbA''PbO$.—$AgHA''$.—Ag_2A''.—Ag_2A'' aq: hexagonal crystals.

The acid **aniline** salt $HA''NH_3Ph$ loses H_2O when its aqueous solution is allowed to stand for a few days, and deposits crystals of the acid anilide $CO_2H.C_3H_4.CO.NPhH$.

The neutral aniline salt when boiled with water gives the phenyl-imide $C_3H_4(C_2O_2)NPh$.

The **ethyl-aniline** and **methyl-aniline** salts do not give anilides when heated. The same is the case with $C_6H_5.NMe_2$ and $C_6H_5.NEt_2$ salts.

The ethyl derivatives of *p*-**toluidine** behave exactly like the corresponding aniline compounds.

Di-phenyl-amine citraconate is only formed at 100°, since the Ph_2NH separates completely on cooling (Michael, *Am.* 9, 194).

Methyl ether Me_2A''. (212° i. V.). S. 3 at 15°. S.G. $\frac{15}{15}$ 1·1168; $\frac{30}{30}$ 1·1050. μ_D 1·4442; μ_H 1·4721 at 15·5°. From citraconic acid, methyl alcohol, and HCl (Perkin, *C. J.* 39, 555). From silver citraconate and MeI. Oil; pleasant odour.

Ethyl ether Et_2A''. (232° i. V.). S.G. $\frac{15}{15}$ 1·051; $\frac{30}{30}$ 1·038. M.M. 10·499 (Perkin, *C. J. Proc.* 3, 99). μ_D 1·4397; μ_H 1·4659 at 16·5° (Gladstone). An alcoholic solution with sodium-aceto-acetic ether at 100° forms an oil $C_{15}H_{24}O_7$ (174°) at 26 mm. (Michael, *J. pr.* [2] 35, 354; *Am.* 9, 118).

Chloride $C_3H_4(COCl)_2$. (95°) at 17·5 mm. S.G. $\frac{16·4}{}$ 1·408. From the acid and PCl_5 (Strecker, *B.* 15, 1640).

Anhydride $C_3H_4C_2O_3$. [7°]. (214° i. V.). S.G. ^{14} 1·241 (Anschütz, *B.* 13, 1542; 14, 2788). Partially converted by distillation into xeronic anhydride (Fittig, *A.* 188, 64). Thiourea at 130° converts it into $NH_2.CS.NH.CO.C_3H_4.CO_2H$ [223°] (Pike, *B.* 6, 1106).

Amide $C_5H_4O_2(NH_2)_2$. Thin colourless tables, sol. water, decomposes at about 186° (Strecker, *B.* 15, 1640).

Imide $C_5H_4O_2(NH)$. [110°]. Formed by distilling acid ammonium citraconate (Gottlieb, *A.* 77, 274; Ciamician a. Dennstedt, *G.* 12, 501). Needles (from water). Br forms $C_5H_3BrO_2(NH)$ [c.181°] and $C_5H_2Br_2O_2(NH)$ [c.144°]. $C_5H_4O_2NAg$ (Mendini, *G.* 15, 184).

Anilide $C_5H_4O_2(NHPh)_2$: [176°], long flat needles, sol. alcohol and ether, slightly in water (Strecker, *B.* 15, 1639).

Acid anilide $CO_2H.C_3H_4.CO.NHPh$. *Citraconanilic acid.* Formed spontaneously by allowing the aqueous solution of the acid aniline salt to stand for a few days. Large trimetric prisms or long needles.

Phenylimide $C_3H_4{<}\begin{smallmatrix}CO\\CO\end{smallmatrix}{>}NPh$. *Citraconanil*: [98°], formed by boiling aniline and citraconic acid in aqueous solution (Michael a. Palmer, *B.* 19, 1375; *Am.* 9, 180).

p-Chloro-phenylimide $C_3H_4:C_2O_2:NC_6H_4Cl$. [114°]. From the preceding and Cl (Morawski a. Klaudy, *M.* 8, 399).

Bromo-phenylimide $C_5H_4O_2.N.C_6H_4Br$, [118°]. From the phenylimide and Br (M. a. K.).

Di-nitro-phenylimide $C_3H_4:C_2O_2:N.C_6H_3(NO_2)_2$. [120°]. From the preceding, HNO_3 and H_2SO_4 (Gottlieb, *A.* 85, 21).

Acid toluide $CO_2H.C_3H_4.CO.NHC_7H_7$ [166°]. Formed by warming an aqueous solution of acid *p*-toluidine citraconate.

p-Tolylimide $C_3H_4:C_2O_2:NC_6H_4Me$. [115°].

(α)-***Naphthylimide*** $C_5H_4O_2NC_{10}H_7$. [142°]. (360°). Yellow plates, sol. most solvents, insol. conc. HClAq (Morawski a. Gläser, *M.* 9, 286).

(β)-***Naphthylimide*** $C_{15}H_{11}O_2N$. [110°]. From citraconic acid and (β)-naphthylamine at 175° (M. a. G.). Pale yellow needles.

m-Carboxy-phenylimide $C_3H_4{<}\begin{smallmatrix}CO\\CO\end{smallmatrix}{>}N.C_6H_4.CO_2H$. [218°]. Formed by boiling *m*-amido-benzoic acid with an aqueous solution of citraconic acid. Prismatic needles, sol. hot alcohol and water, sol. dilute alkalis.

Phenyl-hydrazide $C_3H_4{<}\begin{smallmatrix}CO\\CO\end{smallmatrix}{>}N_2HPh$. [160°]. Bright yellow needles; sl. sol. cold, v. sol. hot, water.

Isomerides of Citraconic Acid *v.* ITACONIC ACID, MESACONIC ACID, CROTACONIC ACID, and ETHYLIDENE-MALONIC ACID.

Constitution of Citraconic acid.—Citraconic acid stands to mesaconic acid in the same relation that maleic acid does to fumaric acid. The formation of allylene by the electrolysis of citraconic and mesaconic acids indicates the presence of a methyl group, so that citraconic acid is methyl-maleic acid, while mesaconic acid is methyl-fumaric acid. On the other hand, itaconic acid is said to give isoallylene $CH_2:C:CH_2$ on electrolysis.

Citraconic and maleic acids differ from the *allo*-isomerides in combining vigorously with halogens and HBr. The ethers of citraconic and maleic acids have higher boiling-points than those of mesaconic and fumaric acids, the difference being much greater between the methyl than the ethyl ethers.

On the other hand, (α)-coumaric ethers have *lower* boiling-points than (β)-coumaric ethers.

Citraconic acid with PCl_5 gives mesaconyl chloride, (α)-coumaric acid with PCl_5 gives (β)-coumaryl chloride (Petri, *B.* 14, 1634).

The indices of refraction of the citraconic and mesaconic ethers are nearly the same for the red end of the spectrum, but the mesaconic ethers refract the violet rays more powerfully.

The ethers of citraconic, maleic, and (a)-coumaric acids contract in volume on changing to the more stable isomerides. The acid aniline salts of citraconic and maleic acids readily change, especially when their solution is evaporated at 100°, into phenylimides; the corresponding salts of mesaconic and fumaric acids are not affected (Perkin, *C. J.* 39, 561).

The initial velocity of etherification is 29·3 for itaconic acid, 37·9 for mesaconic acid, and 47·4 for citraconic acid (Menschutkin, *J. R.* 13, 527; *B.* 14, 2630).

CITRAMALIC ACID *v.* OXY-PYROTARTARIC ACID.

CITRANILIC ACID *v. Phenylimide of* CITRIC ACID.

CITRATARTARIC ACID *v.* DI-OXY-PYROTARTARIC ACID.

CITRAZIC ACID *v.* DI-OXY-PYRIDINE-CARBOXYLIC ACID.

CITRENE *v.* TERPENES.

CITRIC ACID $C_6H_8O_7$ *i.e.* $CO_2H.CH_2.C(OH)(CO_2H).CH_2.CO_2H$. [147°] (Grimaux a. Adam). S.G. 1·54. S. 125 at 15°; 200 at 100°. S. (of $C_6H_8O_7$aq in 80 p.c. alcohol) 87 at 15°; S. (of $C_6H_8O_7$ in absolute alcohol) 75·9 at 15°; S. (of $C_6H_8O_7$ in ether) 2·26 (Bourgoin, *Bl.* [2] 29, 244); S. (of $C_6H_8O_7$ in ether) 9·1 (Lippmann, *B.* 12, 1650). H.F. 354,000 (v. Rechenberg).

Occurrence.—In lemons, oranges, cranberries, cowberries, and sundew (*Drosera intermedia*); together with malic acid in red currants, gooseberries, whortleberries, raspberries, and cloudberries (*Rubus Chamæmorus*); together with both malic and tartaric acids in tamarinds and mountain ash berries (Scheele, *Opuscula*, 2, 181; Berzelius, *A. Ch.* 94, 171; [2] 52, 424, 432; 67, 303; 70, 215; Robiquet, *A. Ch.* [2] 65, 68; Liebig, *A.* 5, 134; 26, 119, 152; 44, 57; Marchand, *J. pr.* 23, 60; Cahours, *A. Ch.* [3] 19, 488; Pebal, *A.* 82, 78; 98, 67; Tilley, *J. Ph.* 13, 305; Perret, *Bl.* [2] 5, 42; Warrington, *C. J.* 28, 925; Stein, *B.* 12, 1603; Kossovic, *C. C.* 1887, 1157). Occurs also in certain plants, *e.g.* celandine (Haitinger, *M.* 2, 485), leaves of the wild cherry (Rochleder, *Z.* [2] 6, 176), *Lupinus luteus*, *Vicia sativa* (vetch), *Vicia Faba*, *Pisum sativum* (peas) and white beans (*Phaseolus*) (Ritthausen, *J. pr.* [2] 29, 357). Occurs as lime and potash salt in tobacco, and in the juice of lettuce. Occurs in the root and leaves of madder (Rochleder, *A.* 80, 322; Willigk, *A.* 82, 343), in beetroot (Michaelis, *J.* 1851, 394; *J. pr.* 54, 184; Schrader, *A.* 121, 370), and in young vines (Wittstein, *J.* 1857, 520; *Vier. pr. Pharm.* 6, 192).

Synthesis.—s-Di-chloro-acetone combines with hydrogen cyanide forming $(CH_2Cl)_2C(OH).CN$ which is converted by saponification into $(CH_2Cl)_2C(OH).CO_2H$, whence KCy readily forms $(CN.CH_2)_2C(OH).CO_2H$ which is converted by treatment with HCl into citric acid (Grimaux a. Adam, *A. Ch.* [5] 23, 356; *C. R.* 90, 1252).

Preparation.—Lemon juice is allowed to undergo incipient fermentation, and is then boiled with chalk and lime. The ppd. calcium citrate is decomposed by an equivalent quantity of H_2SO_4.

Properties.—Usually crystallises in efflorescent trimetric prisms (containing aq) *a:b:c* = ·6068:1:·4106. Different specimens of crystallised citric acid when powdered and left over H_2SO_4 lose water at very different rates (Grosjean, *C. J.* 43, 331). From boiling solutions citric acid separates in anhydrous crystals (Sarandinaki, *B.* 5, 1101). Crystals containing 2aq may sometimes be obtained (Cloez). Lime water produces little or no pp. in the cold, but calcium citrate is ppd. on boiling. Calcium citrate is insoluble in KOH; it dissolves in NH_4Cl, but is reppd. on boiling. Citric acid differs also from tartaric acid in not forming an insoluble acid potassium salt. Boiling, strongly alkaline, permanganate is reduced by citric acid to manganate only, the liquid becoming green, whereas in the case of tartaric acid the reduction proceeds further, the liquid becoming brown (Chapman a. Smith, *Laboratory*, 1, 39; *cf.* Wimmel, *Z.* [2] 5, 286). $FeCl_3$ gives a light yellow pp. in a hot solution of an alkaline citrate; the pp. dissolves in excess of the citrate (Kämmerer, *Fr.* 8, 298). Silver citrate dissolves in hot water without blackening. Conc. $K_2Cr_2O_7$Aq is blackened in the cold by tartaric acid but not by citric acid.

Estimation (in lemon juice).—The juice is neutralised with Na_2CO_3, $CaCl_2$ is added, and the liquid boiled. The pp. is collected and washed. The filtrate and washings are treated with NH_3 and evaporated to a small bulk. Some more calcic citrate then separates (Grosjean, *C. J.* 43, 332; *cf.* Fleischer, *Ar. Ph.* [3] 5, 97; Allen, *C. N.* 32, 277; Creuse, *Ph.* [3] 2, 547). A second concentration may then be effected, when a third quantity sometimes separates. Turmeric is better than litmus as an indicator in alkalimetric experiments with citric acid (F. Watts, *S. C. I.* 5, 214).

Reactions.—1. By *heat* it is split up at 175° into H_2O and aconitic acid $C_6H_6O_6$, which on dry distillation again splits up into CO_2 itaconic acid $C_5H_6O_4$, citraconic anhydride $C_5H_4O_3$, and acetone.—2. By heating with *water* (10 pts.) at 160° it is split up into itaconic acid and CO_2 (Markownikoff a. Purgold, *Z.* [2] 3, 264).—3. Citric acid (100 g.) heated with *water* (50 g.) and sulphuric acid (100 g.) for 5 hours gives aconitic acid which separates on cooling (Hentschel, *J. pr.* [2] 35, 206). 100 g. citric acid heated with 100 g. water and 5 g. H_2SO_4 at 170° give aconitic and itaconic acids (Pawolleck, *A.* 178, 152).—4. Conc. H_2SO_4 at 40° gives off CO, CO_2, and acetone, and forms an acid whose acid barium salt is $(C_5H_7SO_5)_2Ba$, and is converted by baryta-water into $(C_8H_5SO_4)_2Ba$ (Wilde, *A.* 127, 170).—5. On dry distillation with glycerin, it gives, besides acetone, acroleïn, CO, and CO_2, a distillate containing the pyruvic ether of glycide

$CH_2.CH.CH_2.O.CO.CO.CH_3$ (the two CH_2/CH joined through O). [82°]. (241°)

(De Clermont a. Chautard, *C. R.* 105, 520).—6. Conc. HClAq at 150° gives aconitic acid; at 200° it also forms diconic acid $C_9H_{10}O_6$, and gives off CO and CO_2 (Hergt, *J. pr.* [2] 8, 373).—7. An aqueous solution mixed with yeast and chalk and exposed to the air at 25° forms acetic and butyric acids (How, *C. J.* 5, 1, Personne, *C. R.* 36, 197).—8. *Chlorine* acting on a conc. aqueous solution of sodium citrate forms hexa-chloroacetone and chloroform. Br acts in the same way (Cloez, *C. R.* 53, 1120).—9. *Potash-fusion* gives oxalic and acetic acids (Liebig, *A.* 26, 158). 10. Acetone is formed by distilling sodium citrate with lime (Freidl, *M.* 4, 151).—11. Anhydrous citric acid is converted by a mixture of fuming HNO_3 (1 pt.) and H_2SO_4 (2 pts.) into the **nitrate** $C_3H_4(ONO_2)(CO_2H)_3$ erroneously called nitro-citric acid. It is insol. ether, and forms insoluble salts $Ba_3A'''_2$ and $Pb_3A'''_2$ (Champion a. Pellet, *Bl.* [2] 24, 448).—12. Citric acid (1 mol.) heated with *glycerin* (1 mol.) at 100° forms glyceryl citrate $C_3H_5.C_6H_5O_7$ a glassy mass, insol. water (Bemmelen, *J. pr.* 69, 84). Excess of glycerin at 170° gives so-called **citro-diglycerin** $C_{12}H_{18}O_{10}$(?).—13. Citric acid (1 mol.) heated with *mannite* (1 mol.) at 140° forms **citromannitan** $C_{12}H_{14}O_9$ (Bemmelen, *J.* 1858, 435). Excess of citric acid (2 mols.) heated with mannite at 150° forms **dicitromannitan** $C_{18}H_{20}O_{15}$. Both bodies are amorphous.

Salts.—NH_4H_2A''': triclinic crystals.—$(NH_4)_2HA''$. S.G. $\frac{22}{4}$ 1·479 (Clarke, *Am.* 2, 174).—$(NH_4)_3A'''$ aq: deliquescent. Ferric and aluminium oxides, freshly precipitated, dissolve in a solution of ammonium citrate, and from the solutions when evaporated salts of the general type $C_6H_5O_7H(NH_4)_2(C_6H_5O_7(NH_4)_2)_3M2H_2O$ crystallise out. Similarly magnesium, manganese, nickel, cobalt, zinc, copper, and mercuric oxides dissolve in ammonium citrate to form salts of general type $[C_6H_5O_7(NH_4)_2]_2M$ generally with 1 mol. H_2O. Solutions of these salts are not precipitated by ammonia, the alkaline hydroxides and carbonates, but completely precipitated by H_2S or ammonium sulphide. The oxides and carbonates of Ba, Sr, and Ca decompose boiling solutions of ammonium citrate forming insoluble pps. of the corresponding salts $Ca_3A'''_2$, &c. (Landrin, *A. Ch.* [5] 25, 233; *C. R.* 86, 1336).—$(NH_4)_3H_3A'''_2$ (Heusser, *P.* 88, 121).—Li_3A''' (?) (Thomson, *Ph.* [3] 13, 783).—NaH_2A''' aq.—Na_2HA''' aq: needles.—Na_3A''' 5½aq. S.G. $\frac{23·8}{4}$ 1·858 (Clarke, *Am.* 2, 174; Kämmerer, *A.* 148, 294; 170, 176). Trimetric prisms or groups of silky needles. — Na_3A''' 2aq (Heldt, *A.* 47, 157). — KH_2A''' 2aq. — K_2HA'''. — K_3A''' aq.—$K_2(NH_4)_2HA'''_2$.—$K_2(NH_4)A'''$.—$K_3Na_3A'''_2$ 6½aq. $K_3Na_3A'''_2$ 11aq.—Tl_3A''' (Kuhlmann, *C. R.* 55, 607).—$Ba_3A'''_2$ 7aq: amorphous pp.—$Ba_3A'''_2$ 5aq: groups of minute needles, formed by boiling the above with water.—$Ba_3A'''_2$ 3½aq: minute monoclinic prisms, formed by treating either of the two preceding salts with ammonia.—$Sr_3A'''_2$ 5aq: minute silky needles.—$Sr_3A'''_2$ 2aq. $Sr_7H_2(C_6H_4O_7)_4$ 11aq. — $Sr_7H_2(C_6H_4O_7)_4$ 2½aq.—$Ca_3A'''_2$ 4aq. From Na_3A''' and $CaCl_2$: pp. changed in water at 100° into minute transparent needles. $Ca_3A'''_2$ 7aq.—$CaH_2A'''_2$ aq.—$Mg_5H_2(C_6H_4O_7)_3$ 8aq. $Mg_3A'''_2$ 9aq. — $Mg_3A'''_2$ 5½aq. —$Mg_3A'''_2$ 7aq. — $Mg_{11}H_7(C_6H_4O_7)_6$ 13aq. — $Mg_9H_4(C_6H_4O_7)_5$ 3aq. — $Mg_3A'''_2$ 14aq.—$Mg(NH_4)_4A'''_2$ 2aq (Landrin, *C. R.* 86, 1336). — $Zn_3A'''_2$ 2aq. — $Zn_8H_4(C_6H_4O_7)_6$. — $Zn_5H_2A'''_4$ 2aq.—$Zn(NH_4)_4A'''_2$.—$Cd_3A'''_2$ ½aq.—$Cd_3A'''_2$ 10aq.—$Cd_9H_2(C_6H_4O_7)_5$ 18aq: needles.—$Cd_9H_2(C_6H_4O_7)_5$ 27aq. — $Cu_2C_6H_4O_7$ 2½aq: *green crystalline precipitate which is obtained by boiling a solution of cupric carbonate in citric acid.*—$Cu_5H_2(C_6H_4O_7)_3$ 15aq: greenish pp. got by adding alcohol to the above solution.—$Cu(NH_4)_4A'''_2$ aq (Landrin, *C. R.* 86, 1336).—$Pb_3A'''_2$ 3aq: crystalline pp. from lead nitrate and Na_3A'''. — $Pb_2C_6H_4O_7$ 2aq: amorphous; got by heating the preceding with ammonia.—$Pb_3A'''_2$ aq: amorphous pp. from alcoholic $Pb(OAc)_2$ and citric acid. — $PbHA'''$: crystals, v. sol. water. — $Pb_3A'''_2Pb_2O_2$ 3aq (at 100°) (Otto, *A.* 127, 175).—$Pb_3A'''_2Pb_4O_4$. — $Hg(NH_4)_4A'''_2$. — $Co_3A'''_2$ 14aq: amorphous.— $Co(NH_4)_4A'''_2$ 4aq — $Ni_3A'''_2$ 14aq: amorphous. — $Ni(NH_4)_4A'''_2$ 4aq. —$Mn_3A'''_2$ 2aq: crystalline powder formed by boiling citric acid with $MnCO_3$ (Heldt); the following salts are formed at the same time (K.). Sodium citrate does not precipitate salts of manganese. — $MnHA'''$ aq.—$Mn_3A'''_2$ 9aq: trimetric prisms.—$Mn_5H_2(C_6H_4O_7)_3$ 15aq.—$Mn_7H_2(C_6H_4O_7)_4$ 18aq.—$Mn(NH_4)_4A'''_2$.—$FeHA'''$ aq: crystalline powder formed by boiling iron with aqueous citric acid.—$FeNaA'''$: apple-green scales (Rother, *Ph.* [3] 13, 629).—$Fe(OH)Na_2A'''$: amorphous grass-green powder. — $FeNa_2H_2A'''_2$. — $FeNa_2H_2(PO_4)A'''$. — FeA''' 1½aq: got by dissolving $Fe(OH)_3$ in citric acid. Light brown film.—$Fe(OH)HA'''$ 2aq (Schiff, *A.* 125, 147).—$Fe(NH_4)_3A'''_2$: greenish-yellow mass.—$Fe(NH_4)_2HA'''_2$.—$Fe(NH_4)H_2A'''_2$. $(FeO)_2(NH_4)A'''$ 4aq. — $FeA'''(NH_3)_3$ 3aq. — $Fe_2(NH_4)_2(C_6H_4O_7)_2$ 3aq (Méhu, *J.* 1873, 570). — $Fe(OH)(NH_4)_4A'''_2$ 2aq. — $Al(OH)(NH_4)_4A'''_2$. — SmA''' 6aq: amorphous pp. sol. ammonia. The ammoniacal solution does not become turbid on heating (Clève, *Bl.* [2] 43, 172).—$Y_3A'''_2$ 14aq.—LaA''' 3½aq (Czudnowicz, *J.* 1860, 128; *J. pr.* 80, 31). — CeA''' 3½aq. — $K_3SbA'''_2$ 2½aq: hard prisms grouped in tufts.—BiA''': granular pp. obtained by boiling bismuth nitrate with citric acid (Rother, *Ph.* [3] 6, 764; Cavazzi, *G.* 14, 289). —$(BiO)(NH_4)_2A'''$: obtained, together with the following body, by boiling the preceding with ammonia. — $(BiO)(NH_4)HA'''$. — $BiA'''4Bi(OH)_3$: gelatinous pp.—$BiA'''(NH_3)$ 3aq (Bartlett, *C. N.* 11, 28).—$FeA'''BiA'''(NH_3)_3$ 3aq.—Ag_3A''': powder; crystallises from water in needles. — Ag_2HA''' (Rönnefahrt, *J.* 1876, 562).—$Ag_3A'''(NH_3)$ 1½aq (Wöhler, *A.* 97, 18).—Ag_6A''' (?) (W.): got by heating Ag_3A''' at 100° in a current of hydrogen. — $Ag_2CaC_6H_4O_7$. — **Telluro-citrate.** $K_2A'''_2TeOH_2$ aq: leaflets, v. sol. water; formed by adding citric acid to a solution of potassium tellurite and evaporating (Klein, *C. R.* 102, 47).—**Boro-citrates.** Boro-citric acid $H_6A'''_2HBO_2$ at 80° is formed by dissolving boric acid (1 mol.) in a solution of citric acid (2 mols.). It is a deliquescent mass. The boro-citrates are formed by dissolving boric acid in solutions of the citrates. The magnesium borocitrates do not crystallise.—$Na_3A'''3HBO_2$.—$Na_2HA'''2HBO_2$.—$NaH_2A'''HBO_2$.—$K_2HA'''2HBO_2$.—$K_3A'''3HBO_2$. $KH_2A'''HBO_2$.—$KH_5A'''_22HBO_2$.—$LiH_2A'''HBO_2$.—$Li_2HA'''2HBO_2$.—$Li_3A'''3HBO_2$. $MgH_4A'''_2HBO_2$.—$Mg_2H_2A'''_24HBO_2$.—$Mg_3A'''_26HBO_2$ (Scheibe, *Ph.* [3] 11, 389).—**Aniline salt** $NPhH_3C_6H_8O_7$. Needles (Pebal, *A.* 82, 91). At 145° it changes to the phenylimide. **ψ-Cumidine salt** $C_6H_2Me_3NH_2H_3A'''$ [133°] (Schneider, *B.* 21, 660).

Methyl ether MeH_2A''' (Demondesir, *A.* 80, 302).

Di-methyl ether Me_2HA''' (St. Evre, *A.* 60 325).

Tri-methyl ether Me_3A'''. [79°]. (c. 285°); (176° at 16 mm.). Formed, together with the two preceding bodies, by passing HCl into a solution of citric acid in MeOH (St. Evre, *C. R.* 21, 1441). Triclinic crystals. Partly split up on distillation into H_2O and tri-methyl aconitate (271°). PCl_5 gives oily $C_3H_4Cl(CO_2Me)_3$.

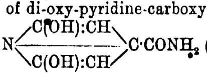
Acetyl-trimethyl ether $C_3H_4(OAc)(CO_2Me)_3$. (281°); (171° at 15 mm.).

Mono-ethyl ether EtH_2A'''. Formed by the action of sodium amalgam upon wet Et_3A''' (Claus a. Roennefahrt, *B.* 8, 866). Formed also by boiling citric acid with acetic ether (Kreitmair, *B.* 8, 737). Thin prisms; v. sol. water, alcohol, and ether.—Na_2EtA''' (at 100°); prisms.—Ag_2EtA'''.

Di-ethyl ether Et_2HA'''. (218°) at 60 mm. Formed, together with the preceding, by the action of sodium amalgam on wet citric ether.—$NaEt_2A'''$: deliquescent. *Formation.*—(Conen, *B.* 12, 1653; Ruhemann, *C. J.* 51, 404).

Tri-ethyl ether Et_3A'''. (218° at 60 mm.) (Ruhemann, *B.* 20, 799; *C. J.* 51, 404); (213° at 35 mm.); (263° at 300 mm.) (Conen, *B.* 12, 1653). S.G. $\frac{20}{4}$ 1·137 (C.). μ_β 1·4513. R_∞ 105·09 (Brühl). Formed by heating citric acid with alcohol and H_2SO_4, or, better, by saturating an alcoholic solution of citric acid with HCl (Thénard, *Mém. d'Arcueil*, 2, 12; Malaguti, *A. Ch.* 63, 197; Dumas, *C. R.* 8, 528; Marchand, *J. pr.* 20, 318; Heldt, *A.* 47, 157; Demondesir, *C. R.* 33, 227; Pebal, *A.* 98, 67; Claus, *B.* 8, 867). Oil; v. sol. alcohol and ether. It boils with decomposition at 280°.

Acetyl-tri-ethyl-ether $C_3H_4(OAc)(CO_2Et)_3$: (288°); (229° at 100 mm.), (214° at 40 mm.); S.G. $\frac{15}{15}$ 1·1459. By the action of strong aqueous NH_3 it is converted into the amide of di-oxy-pyridine-carboxylic acid (citrazimide)



$N\Big\langle\begin{matrix}C(OH):CH\\ \rule{4em}{0.4pt}\\ C(OH):CH\end{matrix}\Big\rangle C\cdot CONH_2$ (Ruhemann, *B.* 20, 799; *C. J.* 51, 404; *cf.* Wislicenus, *A.* 129, 175). Yields a phenyl-hydrazide [128°].

Tetra-ethyl ether $C_3H_4(OEt)(CO_2Et)_3$. S.G. $\frac{20}{4}$ 1·1022. μ_β 1·4548. R_∞ 119·97 (Brühl). Thick liquid. Bitter taste. (238° at 150 mm., and about 290° at 760 mm.). With PCl_5 it gives aconitic ether (Conen, *B.* 12, 1653).

Tri-n-propyl ether $C_3H_4(OH)(CO_2Pr)_3$. (198°) at 13 mm.

Acetyl-tri-n-propyl ether $C_3H_4(OAc)(CO_2C_3H_7)_3$. (205° at 13 mm.). When heated to 250°–280° the acetyl ethers readily split off acetic acid, yielding the corresponding ethers of aconitic acid (Anschütz a. Klingemann, *B.* 18, 1953).

Mono-isoamyl ether $C_5H_{11}H_2A'''$ (Breunlin, *A.* 91, 318). — $(NH_4)_2(C_5H_{11})A'''$. — $NaH(C_5H_{11})A'''$.—$KH(C_5H_{11})A'''$.—$Pb_3(C_{11}H_{15}O_7)_2$. $CaH_2(C_5H_{11})_2A'''_2$ *x*aq: laminæ.

Ethyl isoamyl ether $C_5H_{11}EtHA'''$. Oil.

Tri-phenyl ether $C_3H_5O(CO_2Ph)_3$. [125°]. From citric acid, phenol and $POCl_3$ (Seifert, *J. pr.* [2] 31, 470).

Mono-amide $C_3H_5O(CO_2H)_2CONH_2$. *Citromonamic acid.* [188°]. Colourless crystals; extremely sol. water, less sol. alcohol, insol. ether and ligroïn. Formed as a by-product in the preparation of the tri-amide. By boiling with HCl, or by heating with 75 p.c. H_2SO_4, it is converted into citrazinic acid $C_6H_5NO_4$.—**Salt.** $C_6H_7O_3NAg_2$: white pp.

Di-amide $C_3H_5O(CO_2H)(CONH_2)_2$: *citro-di-amic-acid*: [158°]; white plates; v. sol. water, nearly insol. alcohol and ether. Formed as a by-product in the preparation of the tri-amide. By boiling with HCl, or by heating with 75 p.c. H_2SO_4, it is converted into citrazinic acid.—$C_6H_9O_5N_2Ag$: crystalline pp.

Tri-amide $C_3H_5O(CONH_2)_3$: [210°–215°]; colourless crystals; S. (at 18°) = 2·7; (at 100°) = 33·3; insol. alcohol, ether, &c. Prepared by the action of strong aqueous NH_3 (·88) in the cold upon the tri-methyl ether of citric acid. By heating with HCl or with 75 p.c. H_2SO_4 it is converted into citrazinic acid (Behrmann a. Hofmann, *B.* 17, 2682).

Tri-methyl-amide $C_3H_4(OH)(CO.NHMe)_3$: [124°]; white prisms, v sol. cold water.

Phenylimide $C_3H_4(OH)(CO_2H)(C_2O_2NPh)$. *Citranilic acid.* Formed by heating citric acid (1 mol.) with aniline (1 mol.) at 150° (Pebal, *A.* 82, 92). Crystalline spherules (from water).—$AgC_{12}H_{10}NO_5$.—$NPhH_2C_{12}H_{11}NO_5$.

Dianilide $C_3H_4(OH)(CO_2H)(CONPhH)_2$. [150°]. Formed by boiling the di-phenyl-amide-imide with ammonia. Concentric groups of silky needles (from alcohol).

Di-phenyl-amide-imide $C_3H_4(OH)(CONPhH)(C_2O_2NPh)$. Formed by heating the aniline salt of the phenylimide. Hexagonal plates; sol. alcohol.

Tri-anilide $C_3H_4(OH)(CONPhH)_3$. Formed by heating normal aniline citrate. Prisms (from alcohol). Insol. alkalis.

p-Tolyl-imide $C_3H_4(OH)(CO_2H)\Big\langle\begin{matrix}CO\\CO\end{matrix}\Big\rangle NC_7H_7$: [173°]; small white crystals; v. sol. alcohol, ether, and hot water, sl. sol. cold water. Formed by heating mono-*p*-toluidine citrate at 160°–170°.

Di-p-tolyl-amide-imide $C_3H_4(OH)(CO.NHC_7H_7)\Big\langle\begin{matrix}CO\\CO\end{matrix}\Big\rangle NC_7H_7$: [205°]; small granular crystals; m. sol. alcohol and ether, insol. water. Formed by heating 1 mol. of citric acid and 2 mols. of *p*-toluidine for three hours at 160°–170°.

Di-p-tolyl-di-amide $C_3H_4(OH)(CO.NHC_7H_7)_2(CO_2H)$: [161°]; small needles; sol. alcohol and ether, insol. water. Formed by heating the preceding compound with aqueous NH_3.

Tri-p-tolyl-tri-amide $C_3H_4(OH)(CO.NHC_7H_7)_3$: [189°]; silky white microscopic needles; sl. sol. alcohol, insol. water. Formed by heating 1 mol. of citric acid and 3 mols. of *p*-toluidine at 140°–145° (Gill, *B.* 19, 2352).

Di-ψ-cumyl-amide-imide $C_3H_4(OH)(CO.NHC_6H_2Me_3)(C_2O_2NC_6H_2Me_3)$. [173°]. The chief product of the action of ψ-cumidine (2 mols.) on citric acid (1 mol.) at 160° (Schneider, *B.* 21, 660). Prisms; v. sol. alcohol.

Di-ψ-cumidide $C_3H_4(OH)(CO_2H)(CO.NH.C_6H_2Me_3)_2$. [194°]. Formed by treating the preceding with alkalis.—NaA'. [236°].

Tri-ψ-cumidide
$C_3H_4(OH)(CO.NH.C_6H_2Me_2)_3$: [185°]; white powder, sl. sol. alcohol. Formed by heating citric acid (1 mol.) with ψ-cumidine (3 mols.).

Benzidide

$$C_3H_4(OH)(CO_2H)\left\langle\begin{array}{l}CO.NH.C_6H_4\\ \qquad\qquad\;|\\ CO.NH.C_6H_4\end{array}\right.$$

. From benzidine and citric acid at 150°. Carbonises above 300°. Crystalline powder.

Tolylene-diamide

$$C_3H_4(OH)\left\langle\begin{array}{c}C_2O_2{:}N\\CO.NH\end{array}\right\rangle C_6H_3Me.$$

[187°]. From citric acid and tolylene-diamine. [99°] at 130°. Minute crystals.

Tri-nitro-anilide
$C_3H_4(OH)(CO.NH.C_6H_4NO_2)_3$. [108°]. Formed by nitrating the anilide.

Di-(β)-naphthyl-amide-imide

$$C_3H_4(OH)(CO.NHC_{10}H_7)\left\langle\begin{array}{c}CO\\CO\end{array}\right\rangle NC_{10}H_7:$$

[233°]. Formed by heating 1 mol. of citric acid with 2 mols. of (β)-naphthylamine at 140°–150°. White six-sided plates. Sl. sol. alcohol, insol. water.

Di-(β)-naphthyl-di-amide
$C_3H_4(OH)(CO_2H)(CO.NHC_{10}H_7)_2$: [172°]. Formed by digesting the preceding body with conc. aqueous NH_3 at 170°. Microscopic concentric needles. Insol. water. Weak acid reaction to litmus.—A'Ag.

Tri-(β)-naphthyl-tri-amide
$C_3H_4(OH)(CO.NHC_{10}H_7)_3$: [215°]. Formed by heating the di-naphthyl-amide-imide with (β)-naphthylamine (1 mol.) at 150°–170°. Microscopic prisms. V. sol. alcohol, insol. water.

Di-(α)-naphthyl-amide-imide

$$C_3H_4(OH)(CO.NHC_{10}H_7)\left\langle\begin{array}{c}CO\\CO\end{array}\right\rangle NC_{10}H_7:$$

[194°]. Formed by heating 1 mol. of citric acid with 2 mols. of (α)-naphthylamine at 140°–150°. Six-sided plates (from benzene). V. sol. alcohol, ether, &c., insol. HClAq.

Di-(α)-naphthyl-di-amide
$C_3H_4(OH)(CO_2H)(CO.NHC_{10}H_7)_2$: [149°]. Formed by heating the preceding body with aqueous NH_3 at 150°–160°. Small needles (from alcohol). A'Ag.

Tri-(α)-naphthyl-tri-amide
$C_3H_4(OH)(CO.NHC_{10}H_7)_3$ [129°]. Formed by heating the di-(α)-naphthyl-amide-imide with (β)-naphthylamine (1 mol.) at 150°–170°. Microscopic rhombic prisms (Hecht, *B.* 19, 2614).

ISOMERIDE OF CITRIC ACID *v.* OXY-TRI-CARBALLYLIC ACID.

CITRIDIC ACID *v.* ACONITIC ACID.

CITRONELLOL $C_{10}H_{16}O$ (Gladstone, *C. J.* 25, 47) or $C_{10}H_{18}O$ (Wright, *C. J.* 12, 318). (210°-220°). The chief constituent of the oil of citronella (*Andropogon Nardus* or *Schœnanthus*), a grass cultivated in Ceylon. P_2S_5 appears to form a mixture of terpenes and their polymerides. It combines with Br, forming a dibromide, which is split up by heat into H_2O, cymene, and HBr.

CLADONIC ACID. (β)-*Usnic acid.* [175°]. Occurs in *Cladonia rangiferina* (Stenhouse, *A.* 155, 50; Hesse, *A.* 117, 346). Yields betorcin on dry distillation. Cladonic acid is probably a mixture of usnic and barbatic acids (Paterno, *G.* 6, 113; 12, 231; Stenhouse, *A.* 203, 285).

CLASSIFICATION, CHEMICAL.—In the following article nothing more is attempted than to sketch the outlines of the methods by the employment of which a fairly satisfactory scheme of chemical classification may be attained. 'By the classification of any series of objects is meant the actual or ideal arrangement together of those which are like and the separation of those which are unlike; the purpose of this arrangement being primarily to disclose the correlations or laws of union of properties or circumstances, and secondarily to facilitate the operations of the mind in clearly conceiving and retaining in the memory the characters of the objects in question.'[1]

The importance of classification in chemistry can scarcely be too much insisted upon. The fundamental object is to arrange the various kinds of matter with which chemistry is concerned in classes, so that the connexions between the properties and the composition of these kinds of matter shall be made apparent. Inasmuch as our knowledge of the connexions between the composition and the properties of different kinds of matter is being modified from day to day, it is evident that no system of chemical classification can be regarded at present as a final system. That we may draw the outlines of a scheme of chemical classification, it is necessary first of all to inquire what the objects are which the scheme is to include.

Chemistry concerns itself with the connexions between the properties and the composition of homogeneous kinds of matter; a homogeneous kind of matter being such that all the portions, however small, into which it can be divided, are possessed of the same properties as belong to the mass. But the properties of homogeneous kinds of matter are of two kinds; on the one hand, there are those properties which belong to, or which may be acquired by, the specified kind of matter considered apart from other kinds of matter; on the other hand, there are the properties which are exhibited by the specified kind of matter when it acts on, and is acted on by, other kinds of matter. Chemistry concerns itself more especially with the latter kind of properties. Another classification of the properties of homogeneous kinds of matter may be made; we may pay regard to those properties which are the sums of the properties of the parts of the specified mass of matter; or we may look to those properties which are dependent on the configurations of these parts. Any mass of matter may be conceived to be made up of a vast but finite number of minute particles, which, for the purposes of the investigation in hand, may be regarded as indivisible. These particles may or may not be possessed of the properties which distinguish the mass of matter under consideration; the properties of the mass may be the sum of the properties of the particles, or they may differ from the sum of these properties. In the latter case we assume that the properties of the mass depend, among other conditions, on the relative arrangement of the particles. The weight of any mass of matter, *i.e.*, the force with which the matter is attracted towards the earth's centre, is absolutely independent of the arrangement of the particles, and is equal to the sum of the weights of these particles. The volumes occupied by specified masses of homogeneous gases, on the other hand, are entirely dependent on the relative arrangement of the particles, and are not the sums of the volumes occupied by these particles when separated from each other. Most of the chemical properties of any homogeneous kinds of matter are not the sums of the properties of the particles of such kinds of matter.

---

[1] Stanley Jevons (in *Principles of Science*, ii. 348, 1st ed.) modifying Huxley's definition given in *Lectures on the Elements of Comparative Anatomy* (1864), p. 1.

Such then being, very broadly, the kind of properties considered in chemistry, we have next to inquire as to the meaning of the term composition. This inquiry at once carries us back to properties. Experiment shows that from certain kinds of homogeneous matter there can be obtained two or more different kinds of homogeneous matter, which new kinds of matter are wholly unlike the original in properties, and the mass of each of which is less than the mass of the original; the sum of the masses of the new kinds of matter being, however, always equal to the mass of the original matter. Experiment also shows that from certain kinds of homogeneous matter new kinds of matter can be obtained only by adding on to (or combining with) the original matter one or more different kinds of matter, and that in these cases the mass of the new kind (or kinds) of matter produced is greater than the mass of any one of the kinds of matter which have united to produce it, but is equal to the sum of the masses of all these kinds of matter. Experiment thus enables us to arrange all known kinds of homogeneous matter in two classes; those kinds belonging to the first class, *i.e.*, those from which can be obtained two or more different kinds each unlike, and weighing less than, the original, are called *compounds*; those belonging to the second class, *i.e.*, those which can be changed only by adding on to them some other kind of matter, are called *elements*. A compound may of course be changed by adding on to it a new kind of matter in the same way as an element may be changed; but an element can be changed in this way and in this way only. So far as exact knowledge goes, elements may be said to be completely homogeneous; not only are we unable to separate a specified mass of an element into particles unlike each other, by grinding, or cutting, or dividing the mass in any way, but we have every reason to suppose that the extremely minute particles of matter, by the union of which we are obliged to regard the mass as built up, are themselves completely identical in properties. Although by grinding, or cutting, or dividing by a machine, we cannot separate a specified mass of a compound into particles unlike each other, yet we are certain that the extremely minute particles of matter, by the union of which we are obliged to regard the mass as built up, are themselves built up of yet smaller particles, some of which are wholly unlike some others. But notwithstanding this distinction, which may perhaps be removed as more knowledge is gained, we are justified in applying the term homogeneous kind of matter to elements and compounds alike.

Chemistry then concerns itself with the connexions between the properties and the composition of elements and compounds. By the composition of an element is meant, at present, simply a statement of the name of the element; the element is composed of itself. By the composition of a compound is meant, at present, a statement of the elements by the union of which the compound is produced, and of the mass of each element which goes to produce a specified mass of the compound. But the word composition, as we shall see hereafter, has a fuller meaning than this.

Let us then regard the composition and properties of compounds with the view of placing together those which are like and separating those which are unlike. The moment we attempt to do this, we find that our classification of compounds must include elements also. A series of compounds may be formed by the union of one element with other elements; the properties of these compounds present some points of similarity; the presence in all of them of the specified element is accompanied by certain more or less marked similarities of properties. We wish to connect properties of compounds with composition; therefore we must learn the properties of the elements which by their union produce these compounds; but this involves the study of these elements both as they are in themselves, that is, as they are when unacted on by other elements, and also as their properties are modified when the elements combine with others. We cannot then classify compounds without studying the properties of elements, and we cannot classify elements without studying the properties of compounds.

Compounds may be classified in accordance with (1) the number of elements in each; (2) the qualitative properties of the elements in each; (3) the quantity of the elements in each; (4) the quality and quantity of the elements in each; (5) the functions performed by each; (6) the qualitative and quantitative elementary composition and at the same time the function performed by each.

Making the number of elements in each compound the class-mark, we should have a division of compounds into binary, ternary, quaternary, &c.; but this arrangement would tell very little about the compounds in each class; many compounds may be binary compounds, and yet the differences between them be very great. If the qualitative properties of the elements in a number of compounds are made the class-mark, we should have a division into compounds of oxygen, compounds of chlorine, compounds of iron, and so on; but not only would this arrangement convey little information regarding the compounds classified, but it would involve an immense number of classes, and the classes would overlap each other; *e.g.* the chlorides of iron would be placed both in the class of chlorides and also in that of compounds of iron. Nor can the quantity of the elements in compounds by itself be made the characteristic mark of a class; else we should have vast numbers of quantitative analyses as the sole basis of classification. More hopeful is it to attempt a classification of compounds based on the functions which they perform under stated conditions; this scheme leads to the placing together *e.g.* of acids, basic compounds, metallic compounds, peroxides, anhydrides, &c., &c.; but unless we connect the composition of the acids, the basic compounds, the anhydrides, &c., with the functions of each of these groups, our classification must at the best be one-sided and subject to continual modification. The characteristic mark of a class should be some property or circumstance, or a conjunction of properties or circumstances, which is easily detected, and which belongs to all the members of the class and to no others.

The property which we propose to employ as a class-mark is power of performing a stated action under stated conditions, and with this property we shall endeavour to connect a certain composition. The term composition must be interpreted as meaning not only a statement of the elements, and of the masses of these elements, which produce a specified mass of any given compound, but also a statement of the number of atoms of each element in the atomic complex or reacting chemical unit of the compound in question; or, in the case of gaseous compounds, of the number of elementary atoms in the molecule of the compound. We shall assume the molecular theory of the structure of matter, and the atomic theory of chemistry (*v.* ATOMIC AND MOLECULAR WEIGHTS, vol. i. p. 336). We shall also assume that the reader is familiar with chemical formulæ and notation.

A number of compounds exist which dissolve in water to produce more or less alkaline liquids, that is to say, liquids which exert a corroding action on organic fibres, change the tint of various vegetable colouring-matters, neutralise acids without evolution of any gas, precipitate the hydroxides of most heavy metals from solutions of salts of these metals, have a peculiar soap-like action on the skin, and saponify fats. The compounds which thus dissolve in water to produce alkaline liquids are found on analysis to be binary compounds of oxygen; the element present in combination with oxygen is in each case a metal. Other oxides exist which dissolve in water to produce more or less acidic liquids, or which can be obtained from acids, that is to say, compounds aqueous solutions of which, like alkalis, exert a corroding action on organic fibres and change the tint of various vegetable colouring-matters, which neutralise alkalis with the production of water and salts but without the evolution of any gas, neutralise carbonates of the alkali-metals with evolution of carbon dioxide, and react with many metals to produce compounds composed of the metal and a portion of the elementary constituents of the acid, this action being frequently accompanied by evolution of hydrogen. Oxides which react in this way are, generally speaking, but not always, oxides of non-metallic elements. Other oxides again exist which either do not dissolve in water, or dissolve only in relatively very large quantities of water, and which do not thus produce either alkalis or acids, but react with aqueous solutions of acids to form salts and water. Such oxides are for the most part oxides of well-marked metallic elements. Finally a few oxides exist which do not belong to any one of the three classes already considered; omitting these, the three classes of oxides may be named (1) alkali-forming or alkaline oxides; (2) acid-forming oxides or anhydrides; (3) salt-forming or basic oxides. The alkaline oxides are all oxides of metals, the acid-forming oxides are generally oxides of non-metals, and the salt-forming oxides are oxides of elements most of which are usually classed with the metals. The following list will serve as data on which a comparison of the properties with the composition of each of these classes of oxides may be based:

I. *Alkali-forming oxides.*	II. *Acid-forming oxides.*	III. *Salt-forming oxides.*
Li_2O, Na_2O, K_2O, Rb_2O, Cs_2O; Tl_2O; MgO, CaO, **SrO, BaO**; (?Ag_2O?PbO)	B_2O_3; CO, CO_2; N_2O, N_2O_3, N_2O_4, N_2O_5; SiO_2; P_2O_3, P_2O_5; SO_2, SO_3; Cl_2O, Cl_2O_7; SeO_2; TeO_2, TeO_3; I_2O_5; and the following oxides of metals, viz. V_2O_4, V_2O_5; As_2O_3, As_2O_5; Sb_2O_3, Sb_2O_5; Nb_2O_5; Ta_2O_5; (?Bi_2O_5); (?Di_2O_5); CrO_3; MoO_3; WO_3; Au_2O_3; Ir_2O_3; OsO_3; PtO, PtO_2; PbO_2; MnO_2; SnO, SnO_2; TiO_2; ZrO_2.	Most of the oxides not placed in groups I. and II.; the chief exceptions being H_2O, H_2O_2, NO, and some of the oxides of Cr, Mo, W, and U. The oxides (M_2O) of Li, Na, K, Rb, Cs and Tl, and the oxides (MO) of Mg, Ca, Sr, and Ba, being already classed as alkali-forming, may be omitted from this group, although they react with acids to form salts; some metallic oxides containing relatively much oxygen, *e.g.* Na_2O_2, K_2O_4, BaO_2, Bi_2O_4, &c., form salts by the action of acids but at the same time evolve oxygen.

The alkali-forming oxides are oxides of strongly marked positive elements; if more than one oxide of such an element exists, that with the less oxygen is alkali-forming. The acid-forming oxides are either oxides of the more negative elements (non-metals), or they are the higher oxides of the less positive metals; many of the anhydrides belonging to the latter class do not form acids when acted on by water, but are obtained by removing water (usually by the action of heat) from the hydrated oxides which are themselves feebly acidic in character. By a body of a feebly acidic character is meant a compound which, as a rule, is insoluble or nearly insoluble in water, does not react with aqueous solutions of alkalis to form salts, but gives rise to the production of salts when it is fused with an alkali; the salts thus produced are unstable and are easily separated into their constituent oxides. The salt-forming oxides which are neither alkaline nor acid-forming constitute by far the greater number of the well-marked metallic oxides. The physical properties of the oxides placed in the same class are not necessarily similar; thus CO, CO_2, N_2O_4, SO_2, and some other anhydrides, are gaseous under ordinary conditions of temperature and pressure, but the metallic oxides belonging to this class are solids, many of which melt, if at all, only at high temperatures.

The division of oxides into three classes, an outline of which has now been given, is based to a great extent on the properties of compounds which are produced by the interactions of these oxides with water on the one hand, and with acids on the other hand. In order then more completely to grasp the classification of oxides it is necessary to consider the properties and the classification of alkalis, acids, and salts.

The term *alkali* was originally applied to the ashes of sea-plants; but it was soon extended to include substances which, like the ash of seaweed, easily dissolved in water to form solutions having a soap-like action on the skin, affecting the colour of many vegetable matters, and reacting with acids with effervescence and the production of new substances wherein neither the properties of the alkali nor the acid were prominent. About the middle of the eighteenth century Black proved by quantitative experiments that the effervescence which occurs during the interaction of an acid and an alkali is caused by the outrush of a gas which existed in the alkali in combination with the other constituents of that body. That the same gas may also be obtained from the alkali by the action of heat was also proved by Black. From this time it became customary to distinguish mild or carbonated alkali from burnt or caustic alkali, the former being regarded as a combination of the caustic alkali with carbonic acid gas. Both carbonated and caustic alkali reacted with acids to produce the same substance, in which the properties of alkali and acid were lost, or rather merged into a new set of properties; the action was attended in the case of carbonated alkali with evolution of carbonic acid gas, but in the case of caustic alkali no gas was produced. Continued examination of alkali showed that the composition of the substance thus named was not always the same; this led to the recognition of more than one kind of matter exhibiting the characteristic properties of alkalis. Lavoisier adduced reasons for regarding the various alkalis as compounds of unknown metals with oxygen, but he did not succeed in actually demonstrating their composition. In 1807 Davy decomposed two alkalis, potash and soda, each into oxygen and a metal, by passing an electric current through them when molten, and a year later by the same agency he separated the three earthy bodies, lime, strontia, and baryta —bodies which to a great extent resemble alkalis in their properties—into oxygen, and in each case a metal. The composition of the various bodies having the properties already summarised as characteristic of alkali was now settled; these bodies were oxides of metals. But further investigation showed that aqueous solutions of these metallic oxides did not contain the oxides, but rather compounds of metal, oxygen, and hydrogen, and that these compounds, these hydroxides, were obtained as definite well-marked solid bodies by boiling off the water from the solutions in question. Now as the characteristic properties of alkali belonged to aqueous solutions of the metallic oxides under consideration it was better to apply the name alkali to the hydroxides rather than to the oxides of certain metals. The composition of alkalis is represented by the formula MOH, where $M = Li, Na, K, Rb, Cs$, or the compound radicle NH_4; each of these compounds, except NH_4OH, is known as a definite solid body. An aqueous solution of ammonia, NH_3, reacts towards vegetable colouring-matters, towards acids, towards solutions of the salts of iron, copper, bismuth, tin, and many other heavy metals, in a manner very similar to that in which aqueous solutions of the five alkaline hydroxides, MOH, react towards these classes of substances. The salts formed by the action of acids on the hydroxides in question are generally isomorphous with, and in other properties similar to, the salts formed by the action of the same acids on an aqueous solution of ammonia. For these and a few other reasons the composition of an aqueous solution of ammonia, NH_3, is supposed to be similar to that of aqueous solutions of the solid alkalis; but the compositions of the latter solutions are represented by the symbols LiOHAq, NaOHAq, &c., therefore the composition of the former solution is represented by the symbol NH_4OHAq. As we have hydroxides of the metals lithium, sodium, potassium, &c., so we have a hydroxide of the compound radicle ammonium (NH_4); the former hydroxides are stable solid bodies, the latter exists only in aqueous solution (*v.* AMMONIUM COMPOUNDS, vol. i. p. 200). The hydroxides MO_2H_2 where M is Mg, Ca, Sr, or Ba, all more or less resemble the alkalis; these hydroxides are white solids, which require for solution much larger relative quantities of water than are needed to dissolve equal masses of the alkalis, but which thus produce solutions capable of neutralising acids without effervescence, of changing vegetable colouring-matter in the same way as solutions of the alkalis, of precipitating oxides or hydrated oxides of many heavy metals from solutions of the salts of these metals, of corroding organic fibres to some extent, of saponifying fats, and of quickly combining with carbonic acid to produce carbonates. As all the alkalis and the four compounds of Mg, Ca, Sr, and Ba, just mentioned are compounds each of oxygen, hydrogen, and a metal, and as many other metallic hydroxides, *e.g.* CuO_2H_2, $Fe_2O_6H_6$, &c. &c., do not exhibit alkaline properties, it seems probable that the alkaline qualities of the hydroxides of Li, Na, K, Rb, Cs, Mg, Ca, Sr, and Ba, are to be associated with the properties of the metals, Li, Na, K, . . . Ba.

Thus in our attempts to classify oxides we are obliged to have regard, first, to the properties of alkalis, and then to the properties of the elements of which these alkalis are composed. What, then, are the properties of the metals Li, Na, K, Rb, Cs, Mg, Ca, Sr, and Ba?

The metals Li, Na, K, Rb, and Cs, are silver-white solids, with low melting-points, and very small specific gravities (Li, Na, and K, being lighter than water); the metals are extremely easily oxidised, the process of oxidation being attended with production of much heat; they rapidly decompose cold water with evolution of half the hydrogen of the water decomposed and production of hydroxides MOH which remain in solution; during this process much heat is produced. The metals easily and rapidly combine with the halogens and with sulphur; they are electro-positive to all other metals, and the most electro-positive metal of the group is that with the largest atomic weight (Cs). The compositions of the chief compounds of these metals are represented by the symbols M_2O, MOH, M_2S, MSH, MX ($X = Cl$, Br, I, F, CN), M_2SO_4, $MHSO_4$, MNO_3, M_2CO_3, $MHCO_3$, &c., where $M = Li$, Na, K, Rb, or Cs. These compounds are for the most part white and easily soluble in water; many of them are not chemically changed by the action of heat alone; all compounds of similar composition, *e.g.* all M_2SO_4 or all MCl, are as a rule isomorphous; the sulphates M_2SO_4 form alums by combination with sulphates of the composition M_23SO_4 where $M = Fe$, Al, Cr, In, or Ga. The properties of the hydroxides MOH have already been detailed.

The metals Ca, Sr, and Ba are whitish-yellow solids, the melting-points of which have not been accurately determined, but are somewhere about a red heat; the specific gravities of these metals are represented by small values, which are, however, decidedly greater than those that represent the specific gravities of the metals Li . . . to Cs; these metals are harder than the alkali metals, but, compared with the group of metals as a whole, they are soft; they quickly oxidise in air or oxygen, and decompose cold water with production of much heat, evolution of half the hydrogen of the water decomposed, and formation of solutions of the hydroxides MO_2H_2. In the cases of Li . . . Cs one atom of metal reacts with one molecule of water evolving one atom of hydrogen, in the cases of Ca . . . Ba one atom of metal reacts with two molecules of water evolving two atoms of hydrogen; the metals, so far as exact experiment goes, seem to combine easily and rapidly with the halogens and with sulphur; they are electro-negative to the metals Li . . . Cs, but positive to all other metals. The compositions of the chief compounds of these metals are represented by the symbols MO, MO_2H_2, MS, MS_2H_2, MX_2 ($X = Cl$, Br, I, F, CN), MSO_4, $M2NO_3$, MCO_3, &c., where $M = Ca$, Sr, or Ba. Most of these compounds are white; the oxides and hydroxides are not very soluble, the sulphates and carbonates are nearly insoluble, the chlorides and nitrates are easily soluble, in water; the hydroxides, nitrates, and carbonates are decomposed by the action of heat alone; almost all similar compounds are isomorphous; the sulphates do not form alums, nor do the compounds generally exhibit any marked tendency to form double or basic salts. The properties of the hydroxides have already been detailed.

The metal magnesium is a silver-white solid, the melting-point of which is about 500°-700° (not accurately determined), and the specific gravity is a little greater than that of calcium; the metal is much more malleable and ductile than Li . . . Cs or Ca . . . Ba; it is scarcely oxidised by exposure to air or oxygen at ordinary temperatures, but when rapid oxidation is begun by heating the metal in air or oxygen it proceeds with production of much heat and light. Magnesium decomposes water at 100° very slowly with formation of MgO_2H_2; it does not act chemically on cold water; it does not combine with the halogens or with sulphur at ordinary temperatures. The compositions of the chief compounds of this metal are represented by the symbols MgO, MgO_2H_2, MgS, MgX_2 ($X = Cl$, Br, I, F, CN), $MgSO_4$, $Mg2NO_3$, $MgCO_3$, &c. Most of the compounds are white; the oxide and hydroxide are only very slightly soluble in water; the oxide combines with water to form MgO_2H_2, but much less heat is produced during this process than when CaO, SrO, or BaO, combines with water to form the hydroxide. The hydroxide is easily decomposed by heat alone into oxide and water; the sulphate, nitrate, and haloid salts are easily soluble in water, the carbonate is nearly insoluble in water; many compounds of magnesium salts with those of the alkali metals, &c., are known; some of the magnesium compounds are isomorphous with the similar compounds of Ca, Sr, and Ba, but the isomorphism of the two series of salts is very far from being complete. (For more details of the properties of the three classes of metals *v.* ALKALIS, METALS OF THE, vol. i. p. 114; ALKALINE EARTHS, METALS OF THE, vol. i. p. 112; and MAGNESIUM METALS.)

These facts concerning the metals whose hydroxides are the alkalis, and concerning those whose hydroxides more nearly approach the alkalis than do the hydroxides of any other elements, show that the property of forming an alkaline hydroxide is accompanied by the following properties on the part of an element: low specific gravity, not very high melting-point, small malleability and ductility, softness, occupation of a very positive position in the electrical series of elements, power of rapidly decomposing water with evolution of part of the hydrogen thereof, power of forming salts which are not easily decomposed by heat alone, and many of which are easily soluble in water, great readiness to combine with oxygen and with the halogens. Of all the metals whose properties we have considered in detail, magnesium differs most from the ideal alkali-forming metal; but the hydroxide of magnesium is decidedly less markedly alkaline than the hydroxide of any other metal in the two groups from Li to Sr.

When a given element exhibits a fair number of the properties given above as characteristic of the alkali-forming elements we may conclude that the hydroxide of that element will be more or less alkaline in its properties. There is a certain element characterised by the following properties: specific gravity large (11·9), melting-point moderately low (290°), very soft, malleability and ductility moderate, oxidises rather rapidly in air but action soon stops because of formation of film of oxide, burns rapidly in oxygen at about 300°, does not decompose water until a red-heat is reached; less positive than zinc, which is again less positive than Ca, Sr, or Ba; combines readily with the halogens and with sulphur; most of the salts of this metal are white and easily soluble in water, some of them are isomorphous with, and of similar composition to, salts of potassium. In many respects then this metal approaches the ideal alkali-forming element; but in others, notably its high specific gravity and comparatively negative position in the electrical series, it departs from the alkali-forming type. We should expect the oxide and hydroxide of this metal to present fairly close resemblances to the corresponding compounds of the lithium group of metals, but at the same time to show considerable differences from these compounds. As a matter of fact, the metal forms two oxides and two hydroxides; one pair of these compounds shows close analogies with the corresponding compounds of the alkali metals; the other pair shows fairly marked analogies with the corresponding compounds of aluminium. The metal in question, which is thallium, belongs to two groups of elements; it forms an alkaline oxide and hydroxide Tl_2O and $TlOH$ and another oxide and hydroxide Tl_2O_3 and $TlO.OH$.

Having thus learnt something regarding the properties and compositions of alkalis, let us turn to the second group of compounds which it is necessary to consider before we can complete the classification of oxides; let us briefly consider the group of *acids*. The name *oxygen* perpetuates the Lavoisierian conception of the composition of acids: this element was for Lavoisier emphatically *the* acid-producer. The products of the combustion in oxygen of sulphur, phosphorus, carbon, boron, nitrogen, selenion, and a few other elements, dissolve in water to form solutions which have 'acid reactions,' that is to say, have a sour taste, corrode organic fibres, change the tint of many vegetable colouring-matters, neutralise alkalis with production of salts and water, and dissolve many metals with evolution of gas (generally hydrogen). By removing water from these solutions, at least one definite compound can in most cases be obtained, composed of the element which had been burnt in oxygen, combined with oxygen and hydrogen; when this compound is again dissolved in water the original acid liquid is reproduced. Very many other compounds are known which form aqueous solutions characterised by acidic reactions as above enumerated; most of these compounds are composed of oxygen, hydrogen, and a third element. On the other hand, very many compounds formed by the union of oxygen, hydrogen, and a third element do not form acidic solutions when dissolved in water; and, finally, a few compounds are known, aqueous solutions of which are most definitely acidic, but which do not themselves contain oxygen. Oxygen is therefore not the sole acid-producing element; but the fact remains that by far the greater number of acids are composed of oxygen united with other elements.

Putting into one class all those compounds which dissolve in water with formation of solutions having acidic properties, as these have been already enumerated, and then tabulating the composition of these compounds, it becomes evident that they are all compounds of hydrogen with one or more other elements. Hydrogen then, rather than oxygen, would seem to be the acid-producing element. But further examination of the compounds of hydrogen shows that very many of these are not possessed of any of the characteristics of acids.

Is it possible then to trace any definite connexion between the composition of compounds and the possession or non-possession by them of acidic properties? In attempting to answer this question we are confronted with the great difficulty of chemical classification. We cannot define the class acids, just as we could not define the class alkalis: an ideal acid or alkali may be defined, but it is necessary to place in one or other of these classes many bodies which possess some of the properties of the ideal type, but in other properties diverge more or less widely from that type. Chemical classification, based on the notion of connecting properties with composition, is at best a typical classification, and such a system cannot be regarded as final in an exact science. The mark of a class should be some property or circumstance, or conjunction of these, which is clear and definite, and which belongs to all the members of the class and to no other bodies. But we cannot predicate any one property of acids which is perfectly clear and definite, and the possession or non-possession of which shall determine whether a specified compound is or is not to be admitted to this class. The reaction which occurs between an acid and a metallic hydroxide, or hydrated oxide, more nearly approaches to a good class characteristic than any other single property of acids. The products of the action in question are water and a compound formed of the metal of the hydroxide employed, and the elements of the acid excepting the whole or a part of the hydrogen; such a compound is called a *salt*. The following equations, representing the distribution of the elements of the reacting compounds before and after the mutual actions of various acids and metallic hydroxides, will illustrate, more clearly than can be done in words, the characteristic reaction of an acid:—(the symbol Aq is used to denote that the compound which it follows is dissolved in water)

1. $HClAq + NaOHAq = NaClAq + H_2OAq$.
2. $HNO_3Aq + TlOHAq = TlNO_3Aq + H_2OAq$.
3. $H_2SO_4Aq + KOHAq = KHSO_4Aq + H_2OAq$.
4. $H_2SO_4Aq + 2KOHAq = K_2SO_4Aq + 2H_2OAq$.
5. $H_2SO_4Aq + CuO_2H_2 = CuSO_4Aq + 2H_2OAq$.
6. $2H_4C_2O_2Aq + PbO_2H_2 = Pb(H_3C_2O_2)_2 + 2H_2OAq$.
7. $H_4C_2O_2Aq + NaOHAq = NaH_3C_2O_2Aq + H_2OAq$.
8. $H_3PO_4Aq + TlOHAq = TlH_2PO_4Aq + H_2OAq$.
9. $2H_3PO_4Aq + Fe_2O_6H_6 = 2FePO_4 + 6H_2OAq$.
10. $H_2C_2O_4Aq + CaO_2H_2Aq = CaC_2O_4 + 2H_2OAq$.

An acid, then, may be provisionally defined as a compound of hydrogen with another element, or other elements, which, when dissolved in water, reacts with metallic hydroxides to produce water and a salt; a salt being a compound formed by the union of the elements of the acid, excepting the whole or a part of the hydrogen, with the metal of the metallic hydroxide. This definition is more commonly put into the shorter form, an acid is a compound containing *replaceable* hydrogen; but unless a definite meaning is given to the expression replaceable hydrogen, the definition of acid means nothing: the meaning of the words *replaceable hydrogen* is given in the longer definition of acid stated above. It is found that most compounds which are acids, in accordance with the provisional definition we have adopted, when dissolved in water form more or less corrosive liquids, which affect vegetable colouring matters, have a sour taste, and dissolve many metals with formation of salts and evolution of gas, which is usually hydrogen. But, on the other hand, some compounds which are possessed of many of the properties just detailed do not react with metallic hydroxides to form salts; and, further, some compounds which are not possessed of any of the properties detailed do react with metallic hydroxides to form salts (*v.* ACIDS, vol. i. p. 47).

Looking at the composition of compounds which undoubtedly come under the definition of acid, and which at the same time are characterised by the other four properties enumerated, we find that the elements, or some of the elements, which by their union with hydrogen form the acid, are strongly negative in character; in other words, the element or elements other than hydrogen more or less resemble oxygen in their general chemical characteristics. As a whole, the elements which are classed as non-metallic are those which by union with hydrogen, and generally with hydrogen and oxygen, produce acids. When an acid is a compound of a metal united with hydrogen and another element or elements, for no binary metallic compound is acidic, that other element is always very negative. The following list exhibits most of the well-marked metallic acids which have been obtained in approximate purity:—

Acids containing metals.

H_3AsO_4	H_2SnO_3	H_2SnS_3
$HAsO_3$	—	—
$H_4As_2O_7$	(?H_2PbO_3)	(?H_3AsS_4)
—	—	—

The element which is generally combined with hydrogen and a metal in these acids is oxygen: in a few acids sulphur, in (?) three acids chlorine or bromine, and in a few acids the negative group CN is combined with hydrogen and a metal. It is also to be remarked that the metals which form well-marked acids by union with oxygen and hydrogen are those which, compared with the majority of the metals, are negative.

The general conclusion to be drawn from the facts now reviewed concerning the connexions between the properties and the composition of acids is, that those compounds which are decidedly acidic in properties, as the term acidic properties has been defined, are formed by the union of hydrogen with one or more decidedly negative elements. Acids are seen to be strongly contrasted with alkalis, both in properties and composition.

Oxides were divided (*v.* p. 198) into three groups: alkali-forming, acid-forming, and salt-forming oxides. We can now understand in a general way what is meant by an alkali-forming oxide, or by an acid-forming oxide; it remains to consider the meaning of the term salt-forming as applied to oxides. At the outset, let us remark that a salt-forming oxide may also be acid-forming, and that an alkali-forming oxide also is salt-forming. In considering the meaning of the term salt-forming oxide, it will therefore be necessary to study those typical compounds which possess the property in question to a marked extent. A salt has been already stated to be one of the products of the mutual action of an acid and a metallic hydroxide or hydrated oxide, and to be composed of the elements of the acid, excepting the whole or part of the hydrogen, united with the metal of the metallic hydroxide. It is impossible to generalise the properties of salts; many of them are soluble in water, some are insoluble; aqueous solutions of many exhibit acidic reactions, aqueous solutions of others exhibit alkaline reactions, and aqueous solutions of very many are neutral, *i.e.* exert no corroding action on organic fibres, have no sour or soap-like taste, do not affect vegetable colouring-matter, do not saponify fats, do not dissolve metals, or react with metallic hydroxides, &c. We must be content to look at the composition and the conditions of formation of salts. The composition of salts, regarding them as derivatives of acids, has already been stated. But salts are formed in other ways; they are sometimes produced by the mutual action of an acid-forming oxide and an oxide containing much oxygen, called a peroxide—*e.g.* $BaO_2 + SO_2 = BaSO_4$; sometimes by the action of a salt-forming oxide on an aqueous solution of another oxide from which an acid has not actually been obtained, thus $K_2O + CO_2Aq = K_2CO_3Aq$; sometimes by fusing together a metallic and a non-metallic oxide, *e.g.* $CaO + SiO_2 = CaSiO_3$; sometimes by dissolving the sulphide of a less positive metal in a solution of the sulphide of a very positive metal, thus $As_2S_3 + K_2SAq = 2KAsS_2Aq$, or $WS_3 + K_2SAq = K_2WS_4Aq$; and sometimes in other ways. The products of such actions as these are called salts, either because they can also be directly obtained by the mutual actions of acids and metallic hydroxides, or because they are composed of positive elements (metals) combined with negative elements, of which oxygen is usually one, and which negative elements are known to form acids by union with hydrogen, although the special acid of which any one of these specified salts is theoretically a metallic derivative may not have been prepared. All oxides are in a sense salt-forming; an alkaline oxide reacts with water to form an alkali, and the alkali reacts with an acid to form a salt; an anhydride reacts with water to form an acid, and by the mutual action of this acid and an alkali a salt is produced. But placing on either side those oxides which have been already classed as alkali-forming, and those which have been classed as acid-forming, there remain a great many oxides which are emphatically salt-forming oxides. As a class, these oxides form salts by reacting either with acids or with solution of oxides which act as if they contained acids, although no acid may actually be obtained when the dissolving water is removed, or, lastly, by reacting in the liquid state (not in solution) with the oxides of non-metals or of the more negative metals; examples of these three types of action are exhibited by the following processes:—

(1) $CuO + H_2SO_4Aq = CuSO_4Aq + H_2OAq$,
(2) $BaO + CO_2Aq = BaCO_3 + Aq$,
(3) $K_2O + Ta_2O_5$(fused) $= 2KTaO_3$.

Some salt-forming oxides also produce salts, either by dissolving in concentrated solutions of alkalis, or by combining with alkalis when melted in contact with them; thus freshly ppd. aluminium oxide dissolves in solution of acids to form salts, and also in a concentrated aqueous solution of potash to form a salt; the two actions may be represented thus:

(1) $Al_2O_3 + 6HClAq = Al_2Cl_6Aq + 3H_2OAq$,
(2) $Al_2O_3 + 2KOHAq = Al_2O_4K_2Aq + H_2O$.

Again, moist SnO_2 dissolves in concentrated aqueous potash to form a solution of potassium stannate K_2SnO_3, but the same oxide dissolves in hydrochloric acid to form stannic chloride, $SnCl_4$; inasmuch as the acid H_2SnO_3, of which SnO_2 is the anhydride, is known, we have in stannic oxide, SnO_2, an example of a compound which is at once an acid-forming and a salt-forming oxide. The oxide MnO_2 dissolves in molten KOH to form the salt potassium manganate, K_2MnO_4; the same oxide, when produced in a concentrated solution of lime, combines with the lime to form a series of salts, of which $CaMnO_3$ may be taken as a representative; and, lastly, the same oxide, when hydrated, dissolves in strong sulphuric acid to form a sulphate of manganese $MnO_2.2SO_3$. This oxide, MnO_2, thus exhibits some of the properties of two of the three classes into which we have divided oxides.

We began by proposing to arrange oxides in three classes in accordance with certain prominent reactions of these oxides; that we might attach to the reactions in question such definite meanings as should suffice for classificatory purposes, we were obliged to consider the meaning of the terms which summarise the reactions and composition of three other groups of compounds—acids, alkalis, and salts; that we might grasp the significance of these terms, we had to turn from compounds to elements, and roughly to classify these in accordance with their acid-forming or alkali-forming functions; but we found all this scheme of classification to be based at once on the composition and the functions of the bodies classified, and the word function we were obliged to interpret as implying the notion of mutual action and reaction between at least two kinds of matter. We arrived at no perfectly clear definition of any one of the classes of compounds under examination; we did succeed in conceiving the properties and the composition of a typical acid-forming, alkali-forming, and salt-forming, oxide; but when we applied this conception, gained, it is to be remarked, from the study of actual acid-, alkali-, and salt-forming oxides, to individual compounds, we found that very few of these exhibited all the characteristics which we had laid down as marking off the typical acid-forming from the typical alkali-forming, or both from the typical salt-forming, oxide.

Looking back for a moment at the classification of oxides, and considering what it implies, one thing stands clearly out, namely, that this classification of oxides carries in itself a classification of elements. Those elements which form markedly alkaline oxides fall into one class, those which form oxides which are distinctly anhydrides fall into a second class, and a third class includes those elements the best-marked oxides of which are neither alkali-forming nor acid-forming, but salt-forming. Or, putting the matter in even more general terms, the classification of oxides suggests a means of classifying the elements. Let us put into one class all the elements which, under similar conditions, form compounds similar in composition and function. Let us then examine the elements in a class with the view of finding whether they do or do not exhibit similarities in physical properties. If the result is fairly successful, let us examine more closely into the composition of the compounds belonging to specified classes, and endeavour to learn something of the structure of these compounds in the light which is thrown on structure by the molecular and atomic theory. Finally, let the knowledge which may thus be gained of structure react on that previously amassed concerning function, that by the help of both some advance may be made in finding a solution for the fundamental problem of chemistry, which is, to trace the connexions between changes of composition and changes of properties in homogeneous kinds of matter.

Instead of following the course of this investigation step by step, it will be more advantageous to begin with the leading principle, which has been gained after much laborious inquiry. In the article Atomic and molecular weights a sketch was given of the *periodic law*. The substance of that sketch it would be needless to repeat here; let us rather apply it to the point in hand, namely, the classification of the elements, remembering always that a good classification of elements implies and carries with it a good classification of compounds also.

The classification founded on the periodic law arranges the elements in *groups* and *series* (*v.* vol. i. p. 351); the members of the same group more or less closely resemble each other; the properties of the members of a series vary from member to member so that the last, that is the element with the largest atomic weight, is more unlike the first than any other member of the series. Each series to some extent repeats the characteristics of that which precedes it. The properties of an individual element are chiefly conditioned by (1) the group, (2) the series, to which it belongs, (3) its position in the group and in the series, (4) its relations to elements situated similarly to itself in other groups and series, and (5) the relations of the group and of the series to other groups and series. As regards the characteristics of individual groups and series, and the relations between various groups and series, it should be remarked, (1) that each group is made up of elements belonging to even series and elements belonging to odd series; (2) that an odd and an even series together comprise 14 elements, and that in the cases of series 4 and 5, 6 and 7, and 10 and 11, there is a group of three elements (Group VIII.) forming what is called by Mendelejeff a 'transition-period' from the even to the odd series; (3) that there is certainly no such 'transition-period' connecting series 2 and 3, but that very probably such a period of three elements will be discovered between series 8 and 9; (4) that the elements in the even series, or in the odd series, of any group are more like one another than elements in the even are like those in the odd series; (5) that, omitting series 2 and 3, the passage from an even to an odd series is accomplished by a gradual change of properties, but the passage from an odd to an even series by a more sudden change of properties; (6) that the distinctly non-metallic elements occur in odd series, except in the case of series 2; (7) that, omitting series 2, easily gasified organo-metallic compounds, so far as data go at present, are formed only by elements which occur in odd series; (8) that the properties of hydrogen are so marked, and are typical of such diverse elements, that it is placed in a series [series 1] by itself; (9) that all the members of series 2 [Li to F], and at least the first member of series 3 [Na], are to a great extent marked by peculiar properties, and that the relations of these elements to those in series 4, and in the case of sodium to series 5, are rather markedly different from the normal relations of an odd series to the next odd series, or of an even series to the next even series. The elements Li to Na have been called by Mendelejeff 'typical elements.' The following table (copied with a few changes from one given by Mendelejeff) exhibits the arrangement of the elements in groups and in odd and even series (at. wts. in round numbers):—

	Series							
Groups	1		2	4	6	8	10	12
I.		Typical Elements	Li= 7	K=39	Rb=85	Cs=133	—	—
II.			Be= 9	Ca=40	Sr=87	Ba=137	—	—

	1		3	5	7	9	11	13
	Series							

As regards the mutual relations of groups and series, it should be further remarked that, calling the even series members of a group a family, and the odd series members a family, in groups 1 and 7 the family-character is more marked than the group-character, in groups 3, 4, and 5 the group-character preponderates over the family-character, and in groups 2 and 6 the two characters are about balanced, so that these two groups present, perhaps, the best examples for the detailed study of the application of the periodic law to the classification of elements. Group II. contains the following elements:—

Group II.

Even series:				
2	4	6	8	
Be=9	Ca=40	Sr=87	Ba=137	
Odd series:				
3	5	7	9	11
Mg=24	Zn=65	Cd=112	—	Hg=200

The even series elements in this group are beryllium, calcium, strontium, and barium. The three metals, Ca, Sr, and Ba, are yellowish-white, rather soft, solids, with comparatively small specific gravities; their characteristic properties have already been detailed in the present article (*v.* p. 200). The metal beryllium differs considerably from the other even series members of the group; unlike these metals, it cannot be obtained by electrolysing the chloride; the method by which beryllium is obtained is very similar to that whereby magnesium is prepared, viz. by heating the chloride with metallic sodium. Beryllium appears to be a silver-white, hard, solid; its specific gravity is small (approximately 1·7), melting-point high, not accurately determined, but certainly above 600°; the specific heat of this metal increases rapidly as temperature rises, and approaches a constant value between 400° and 500°. The spectrum of beryllium more nearly resembles that of lithium than of any other element, in the number, relative position, and intensity, of the lines; but the character of the lines of greatest intensity in the beryllium-spectrum closely resembles that of two pairs of lines in the spectrum of calcium. This metal does not oxidise in air at ordinary temperatures, and even when heated in oxygen it is only superficially oxidised; it combines with chlorine and iodine only at high temperatures; when heated with sulphur, no sulphide of beryllium is formed; it very readily combines with silicon. Beryllium does not decompose water even at a red heat; it dissolves in an aqueous solution of potash with formation of beryllium oxide and evolution of hydrogen; it is easily soluble in dilute hydrochloric or sulphuric acid, but has little or no action on nitric acid. The compositions of the salts of beryllium are represented by the same formulæ as express those of the salts of Ca, Sr, and Ba; the oxide BeO does not combine with water, but the hydroxide, BeO_2H_2, can be prepared indirectly; this hydroxide is easily decomposed by heat alone, it resembles the hydroxides of zinc and of aluminium in being soluble both in acids and in aqueous potash, it combines with carbon dioxide to produce $BeCO_3$; the oxide crystallises in the same (hexagonal) form as aluminium oxide; under certain conditions zinc oxide can also be obtained in this form; beryllium oxide usually occurs in combination with alumina and silica, as beryl. Most of the salts of beryllium are white; the nitrate, sulphate, and chloride are soluble, the carbonate and phosphate are insoluble, in water. Beryllium sulphate does not form an alum, but does combine with potassium sulphate to form a double salt having the composition $BeSO_4.K_2SO_4.2H_2O$: the chloride does not form double salts with the alkali chlorides; the carbonate is fairly stable towards heat, but easily forms basic, and also double, salts; the sulphate, which also readily produces basic salts, is completely decomposed into oxide and oxide of sulphur by the action of heat alone. The chloride and bromide of beryllium have been gasified; an ethide, $Be(C_2H_5)_2$, is known; it is a fuming liquid which takes fire when gently warmed in air.

The odd series members of the group we are considering are magnesium, zinc, cadmium, and mercury. The properties of the metal magnesium have already been stated in this article (*v.* p. 200); of the remaining metals, zinc and cadmium are very similar, while mercury differs in many respects from any other member of the group. Zinc and cadmium occur together in minerals, chiefly as sulphides; both are obtained by deoxidising the oxides by hot carbon; both are heavy, moderately hard, tin-white solids (S.G. Zn = 7·2, S.G. Cd = 8·6); both melt at fairly high temperatures (M.P. Zn = 420°, M.P. Cd = 320°), and both can be volatilised at temperatures somewhat under 1000°. Cadmium is ductile and malleable, the ductility and malleability of zinc vary considerably with variations of temperature; both are easily soluble in the ordinary mineral acids, zinc dissolves in concentrated warm aqueous solutions of potash or soda, with evolution of hydrogen and production of an unstable zincate of the alkali metal (xZnO.$y M_2O$); both are nearly unacted on by air or oxygen at ordinary temperatures, but are rapidly burnt to oxides when heated in oxygen; both readily combine with the halogens and with sulphur. The formulæ which represent the compositions of the chief compounds of Be, Ca, Sr, Ba, and Mg, also represent those of the chief compounds of Zn and Cd; almost all similar salts of Zn and Cd are isomorphous. The oxides, MO, do not combine with water to form hydroxides; the hydroxides, MO_2H_2, are quite insoluble in water, and are readily decomposed by heat alone into oxides and water; ZnO_2H_2 is soluble, CdO_2H_2 is insoluble, in aqueous potash. The chloride, sulphate, and nitrate of either metal is soluble, the phosphate and carbonate are nearly, if not altogether, insoluble, in water; these salts show great readiness to form double salts, especially with the alkali metals and with ammonia, and also to form basic salts, but the zinc salts are more ready to undergo the latter changes than the salts of cadmium. Mercury differs from all other metals in being liquid at temperatures above −39°. This metal occurs chiefly as sulphide, from which it may be obtained by heating with iron, and in other ways; it is a silver-white, heavy liquid (S.G. about 13·5); it boils at 350°, and is very easily volatilised; it is unacted on by oxygen until a temperature near 350° is reached, when it slowly combines with oxygen to form HgO. Mercury readily combines with the halogens and with sulphur; it is without action on water; dilute nitric acid quickly dissolves mercury, and it is also soluble in hot concentrated sulphuric acid, but neither boiling hydrochloric, nor boiling dilute sulphuric, acid acts upon it. Mercury forms two series of salts, mercurous salts represented by Hg_2O, Hg_2Cl_2, Hg_2SO_4, $HgNO_3$, &c., and mercuric salts represented by HgO, $HgCl_2$, $HgSO_4$, $Hg2NO_3$, &c.; the latter, as a class, are more soluble in water, and are much more stable, than the former. No hydroxides of mercury are known; HgO is said to be very slightly soluble in water, and also in molten potash. The salts of mercury, especially the mercuric salts, form a great many double compounds, chiefly with the salts of the alkali metals; they also readily form many basic salts; a very large number of compounds of mercury salts with ammonia, and derivatives of ammonia, is known.

The following data present some of the measurements which have been made (chiefly by Thomsen) of the quantities of heat produced during similar changes undergone by the elements, or by compounds of the elements, in the group we are now considering:—[1]

M	[M,Cl^2,Aq]	[M,Br^2,Aq]	[M,I^2,Aq]	[M,O,N^{2}O^{5}Aq]	[M,O]
Ca	187,600	165,800	135,300	177,160	130,930
Sr	195,700	173,800	143,400	185,410	128,440
Ba	196,300	174,400	144,000	187,000	124,240
Mg	186,900	165,000	134,600	176,480	146,000
Zn	112,800	90,900	60,500	102,510	85,400
Cd	96,300	74,400	44,000	86,000	65,600
Hg	53,200[2]	41,480[2]	24,300[2]	37,070	30,670
Hg_2	62,600[2]	50,950[2]	28,400[2]	47,990	42,200

M	[M,Cy^2,2KCyAq]
Zn	62,230
Cd	44,750
Hg	27,780

So far as these data warrant us in drawing general conclusions, it appears that the quantity of heat produced during the occurrence of a similar chemical change increases as the atomic weight of the metal increases in the cases of even series members of Group II., but that the quantity of heat produced decreases as the atomic weight of the metals in odd series of the group increases. Further, it seems that the increase in the even series members is much less for equal increments of atomic weights than the decrease in the odd series members. And lastly it is seen that the value for magnesium, which is the first odd series member of the group, is generally nearly the same as the value for calcium, which is the first even series member for which thermal data have been observed. Unfortunately hardly any thermal measurements have yet been made for compounds of beryllium; the following numbers, taken from Thomsen's work, show that the heat of neutralisation of beryllium hydroxide is very much less than that of the other even series members of the group, or of magnesium, and approaches the values for zinc, cadmium, and mercury:—

---

[1] The square bracket denotes that the thermal value of the chemical change which occurs between the bodies within the bracket is measured; the comma means that chemical action occurs between the bodies the symbols of which are separated by this comma; the symbols of elements and compounds are to be read in grams; the figures represent gram-units of heat produced; the symbol Aq is used to denote so large a mass of water that an increase in this mass would not affect the thermal value of the change. Thus [Ca,Cl^2,Aq] = 187,600 means that 187,600 gram-units of heat are produced when 40 grams of calcium and 71 grams of chlorine combine, in presence of much water, to produce 111 grams of calcium chloride.

[2] These figures represent the heats of formation of *solid* $HgCl_2$, Hg_2Cl_2, $HgBr_2$, Hg_2Br_2, HgI_2, and Hg_2I_2 respectively.

Q	[Q,2HClAq]
BeO_2H_2	16,100
CaO_2H_2	27,900
SrO_2H_2	27,630
BaO_2H_2	27,780
MgO_2H_2	27,690
ZnO_2H_2	19,880
CdO_2H_2	20,290
HgO	18,920

Looking at these thermal measurements as a whole it is clear that, thermally considered, magnesium is very analogous to the three metals Ca, Sr, and Ba; that the three metals Zn, Cd, and Hg form a second class, marked off from the Mg...Ba class; and that, if one may draw any conclusions from the meagre data, beryllium seems to belong to the zinc rather than to the magnesium class. A consideration of the thermal values of the reactions of the metals in Group II. with acids shows that mercury is more widely separated from the other members of the group than these other members are from one another. Thus, take the values of the differences (1) between the heats of formation of the chlorides of the metals and that of gaseous hydrochloric acid, and (2) between the heats of formation of aqueous solutions of the nitrates of the metals and that of aqueous nitric acid; these differences give comparative representations of the quantities of heat produced, or which disappear, when equivalent masses of the metals react (1) with the same (equivalent) mass of gaseous hydrochloric acid, and (2) with the same (equivalent) mass of nitric acid dissolved in much water:—

M	$[M,Cl^2]-[H^2,Cl^2]$	M	$[M,O,N^2O^5Aq]-[N^2O^5,Aq]$
Ca	125,820	Ca	117,520
Sr	140,550	Sr	125,770
Ba	150,740	Ba	127,380
Mg	107,010	Mg	116,840
Zn	53,210	Zn	42,870
Cd	49,240	Cd	26,360
Hg_2	18,600	Hg_x	−11,650 (used)
Hg	9,200	Hg	−22,570 (used)

As a general rule, such thermal data as are given here and elsewhere in this article represent differences between the quantities of energy degraded from more chemically available to less chemically available forms, during similar reactions. Of two systems producible from the same initial system, that one will be the more stable the production of which is attended with the running down of the greater quantity of energy. It is most important to trace connexions between the compositions of chemical systems and the quantities of energy degraded during the production of these systems; but such thermal data as are given here can only be regarded as affording bases for very rough comparisons of the stabilities of the various systems produced by the different chemical operations formulated (*v.* further EQUILIBRIUM, CHEMICAL; and PHYSICAL METHODS).

Further data on which comparisons of the compounds of the elements in Group II. may be based are furnished by (1) the melting-points, and (2) the so-called specific volumes, of similar compounds. The specific volume of a compound is defined as the quotient obtained by dividing the formula-weight by the specific gravity of the solid compound; it represents the volume, in cubic centimetres, occupied by the mass of the solid compound, in grams, represented by the formula of the compound. The difference between the specific volume of a binary compound and that of one of the elements contained in one formula-weight of the compound may be taken as representing the specific volume of the other element in one formula-weight of the compound; these differences afford useful data for comparing similar compounds of elements in the same or different groups:—

Melting-points of chlorides and bromides (approx.).

$BeCl_2$	600°	$BeBr_2$	600°
$CaCl_2$	720	$CaBr_2$	680
$SrCl_2$	825	$SrBr_2$	630
$BaCl_2$	800	$BaBr_2$	810
$MgCl_2$	700	$MgBr_2$	700
$ZnCl_2$	260	$ZnBr_2$	400
$CdCl_2$	540	$CdBr_2$	570
$HgCl_2$	280	$HgBr_2$	240

As regards the melting-points of chlorides and bromides, we see that the five metals Be, Ca, Sr, Ba, and Mg, are closely related to each other, while the three remaining metals of the group, viz. Zn, Cd, and Hg, form a class by themselves. As regards the specific volumes of oxides, we notice that the values increase from BeO to BaO, then fall to MgO, and again increase from MgO to HgO; the great difference between the value for CaO and that for BeO (10), and the smaller difference between the value for BeO and MgO (4), suggest that BeO is more allied to the group MgO ..... HgO than to the group CaO, SrO, BaO. An analogy between BeO and the oxides of Zn, Cd, and Hg, is also pointed to by the value for the specific volume of O in the oxides MO.

Finally, let us tabulate the differences between the values of the atomic weights of pairs of consecutive metals in the group we are considering:—

$$\textit{Even series}\ \left.\begin{matrix}\mathrm{Ca-Be}\\ 40-9\end{matrix}\right\} = 31 \quad \left.\begin{matrix}\mathrm{Sr-Ca}\\ 87-40\end{matrix}\right\} = 47$$

$$\left.\begin{matrix}\mathrm{Ba-Sr}\\ 137-87\end{matrix}\right\} = 50;\ \frac{50+47}{2} = 48{\cdot}5.$$

$$\textit{Odd series}\ \left.\begin{matrix}\mathrm{Zn-Mg}\\ 65-24\end{matrix}\right\} = 41 \quad \left.\begin{matrix}\mathrm{Cd-Zn}\\ 112-65\end{matrix}\right\} = 47$$

$$\left.\begin{matrix}\mathrm{Hg-Cd}\\ 200-112\end{matrix}\right\} = 88 = 44 \times 2;\ \frac{44+47+41}{3} = 44.$$

$$\frac{47+50+41+47+44}{5} = 45{\cdot}8.$$

Omitting the difference Ca-Be, it is seen that the difference between the atomic weights of a pair of consecutive elements approaches the value 45; and that the difference is rather larger in the cases of the elements belonging to even series than in those of elements belonging to odd series. But the difference Ca – Be is only 31: in this respect beryllium stands marked off from the other elements of the group. If the differences between the values of the atomic weights of the first and second even series members of Groups I. to VII. are tabulated, it is found that this difference varies from 32 (K – Li) to 36 (Mn – F), and has a mean value of 34; but 34 is considerably less than 45, which is about the mean difference between any two elements (omitting the elements from Li to Na) in the same group and in consecutive even, or consecutive odd, series.

Looking back at the properties of the elements in Group II., it appears that beryllium is distinctly marked off from the other elements of the group; that calcium, strontium, and barium are more closely related to each other than they are related to any other elements of the group; that the relations between zinc and cadmium are most marked; and that mercury is to some extent separated from the other members of the group. Beryllium approaches magnesium in the method of its preparation; in its high melting-point; in the unreadiness with which it oxidises; in the ease with which its hydroxide is decomposed by heat; in the solubility of its sulphate; in the specific volume of its oxide; and in some other properties. Beryllium approaches calcium, among other respects, in the nature of its spectrum; and in the readiness with which its hydroxide combines with carbon dioxide. In the melting-point of its chloride and bromide, beryllium approaches the three metals calcium, strontium, and barium. The analogies between beryllium and zinc are marked by the following among other properties: action on water; solubility in aqueous potash; crystalline form of the oxides. The solubility of beryllium sulphate in water; the readiness with which basic salts, and also double salts, of beryllium are produced; the existence of gasifiable chloride, bromide, ethide, and propide, of beryllium; the specific volume of oxygen in beryllium oxide; and the thermal value of the neutralisation, by aqueous hydrochloric acid, of beryllium hydroxide; these properties indicate the analogy between beryllium and the three odd series members of the group, zinc, cadmium, and mercury. Calcium, strontium, and barium certainly stand by themselves; but in the specific volume of the oxygen in its oxide, and more especially in the thermal values of similar reactions, the odd series metal magnesium is closely related to these three even series metals. Mercury is marked off from the other elements of the group by the fact that it forms two series of salts, and by the thermal values of the reactions between it and hydrochloric and nitric acids; but in the general character of its persalts, in the melting-points of its chloride and bromide, in the specific volume of its oxide and of the oxygen therein, mercury is clearly related to zinc and cadmium; and in the solubility of its oxide in molten potash, the relationship of mercury more especially to zinc and beryllium is rendered evident. An element has yet to be discovered which shall have an atomic weight equal to about 158, and which shall form a link between cadmium and zinc on one side and mercury on the other.

Putting together all we have learned of the elements and the compounds of the elements in Group II., we see that the group contains certain sub-groups or families, but that the special characteristics of these families are balanced by the strength of the group-character which impresses itself on all the members of the group.

Group VI. comprises the following elements:—

Even series

2	4	6	8	10	12
O = 16	Cr = 52	Mo = 96	—	W = 184	U = 240

Odd series

3	5	7	9	11
S = 32	Se = 79	Te = 125	—	—

We have here two families: the even series members O, Cr, Mo, W, and U; and the odd series members S, Se, and Te. But in many respects the first member of the even series family, oxygen, more resembles the odd series family than it resembles the other members of its own family. There is a distinct line of separation between oxygen on one side and Cr, Mo, W, and U on the other side. The four members of the even series family Cr . . . . U may be divided into two sub-families, Cr and Mo, and W and U; but there are well-marked analogies between Cr and U on the one hand, and between Mo and W on the other hand. Finally, some of the members of the even series family, besides oxygen, show very distinct relations to members of the odd series family; *e.g.* Cr and S, and U and Te, are more or less closely related.

Let us consider these relationships very briefly. The compositions of the binary compounds of O, S, Se, and Te, emphasise the relations between the four elements: we have MH_2, MCl_2, MK_2, MCa, $M(C_nH_{2n+1})_2$, &c., where M = O, S, Se, or Te. The properties of these compounds are also very similar. No hydrides of the other even series members (Cr . . . . U) are known, the best-marked chlorides of these elements are not MCl_2, nor do these elements form compounds with K, Ca, or the radicles C_nH_{2n+1}. There is a less-marked gap between the physical properties of O on one hand, and S, Se, and Te on the other, than between the former element and Cr, Mo, W, and U: thus, the melting-points of S, Se, and Te all lie under 550°, whereas Cr, Mo, and W, are scarcely fusible at the highest attainable temperatures, and U melts only at a full red heat. The specific gravities also of S and Se are less than 5, whereas the values of this quantity for Cr . . . . U vary from 6·7 (Cr) to 19 (W). The specific gravity of Te is about

6·2. The elements S, Se, and Te, are distinctly non-metallic and negative; their oxides are acid-forming; these elements do not replace the hydrogen of acids with formation of salts; in these respects they approach closely to oxygen, which is the typical non-metallic acid-forming element. Tellurium, however, is to some extent separated from selenion and sulphur; it is a white, brittle solid; its haloid compounds are much more stable than those of S or Se; its oxides are not strongly acid-forming; the acids H_2TeO_3 and H_2TeO_4 are easily separated into water and anhydride, they are only slightly soluble in water, and are feeble acids (this statement may be made although the *relative affinities* of these acids have not yet been determined). Thomsen's measurements of the relative affinities of sulphuric and selenic acids (H_2SO_4 and H_2SeO_4), and the confirmation of these results by Ostwald's study of the electrical conductivities of aqueous solutions of these acids with varying masses of water (*v.* AFFINITY, vol. i. pp. 75, 81, 83), show that these two acids are most closely related in their powers of combining with bases. The heat of formation of aqueous solutions of the oxides MO_3, however, point to a closer relation between Se and Te on one hand, than between either of these elements and S on the other hand: thus,

$$[M, O^3, Aq] = \begin{cases} 142{,}410 \text{ when } M = S \\ 76{,}660 \quad ,, \quad M = Se \\ 98{,}380 \quad ,, \quad M = Te. \end{cases}$$

Notwithstanding these resemblances we must admit that oxygen is distinctly cut off from the other members of the group, whether they be even series, or odd series, elements. Thus the thermal values of the formation of hydrides reveal a great gap between O and S: $[H^2, O] = 68{,}360$, but $[H^2, S] = 4{,}740$ (unfortunately values for $[H^2, Se]$ and $[H^2, Te]$ have not yet been determined). Oxygen, like beryllium in Group II., is a so-called 'typical' element; the relations of this element to the odd series family of its group—S, Se, and Te—are not unlike the relations of the typical Be to the members of its group which belong to odd series—Mg, Zn, Cd. Oxygen is distinctly cut off from the even family Cr . . . . U by its physical properties; by the composition of compounds with the same elements, *e.g.* OCl_2, O_2Cl, $CrCl_3$, $MOCl_5$, WCl_6, UCl_4; by the properties of many of these compounds, *e.g.* OCl_2 boils at −18°, $MOCl_5$ and WCl_5 melt between 200° and 300°, the heat of formation of OCl_2 has a large negative value, the heats of formation of chlorides of the other elements have not been determined, but from established analogies there can be no doubt that the numbers representing these heats of formation have large positive values; further the elements Cr, Mo, W, U, act both as acid-forming and salt-forming elements, whereas oxygen is in the most marked way the typical acid-forming element.

The even family Cr . . . U may be broadly divided into two sub-families, Cr and Mo, and W and U. Thus the specific gravities of Cr and Mo are, respectively, 6·7 and 8·5, of W and U 19 and 18·5; the specific volumes (*i.e.* atomic weight ÷ S.G. of solid) are 7·7 and 11·3, and 9·7 and 12·9. Some of the oxides of chromium, *e.g.* Cr_2O_3, are distinctly salt-forming, but CrO_3 is the anhydride of a well-marked acid, H_2CrO_4, from which is derived a large series of well-marked salts, for the most part isomorphous with similar sulphates and manganates. The oxides of Mo can scarcely be classed as salt-forming, although MoO_2 is said to dissolve in acids without evolution of oxygen; MoO_3 is the anhydride of an acid H_2MoO_4; two classes of chromium salts exist, chromous salts represented by $CrSO_4 7H_2O$, and the more stable chromic salts represented by $Cr_2 3SO_4$, $Cr_2 6NO_3$, &c.; hydrated oxides of the composition $MOxH_2O$, both of Cr and Mo, seem to exist, but they are easily oxidised to compounds of the form $M_2O_3xH_2O$. The relations of W to U are similar to those of Mo to Cr; few, if any, distinct salts are known obtained by the replacement of the hydrogen of acids by W, but U forms two well-marked series of salts, represented by USO_4 and UO_2SO_4 respectively; the oxides WO_3 and UO_3 are both anhydrides of acids $H_2W(U)O_4$. The oxide WO_2 resembles MoO_2 in that it dissolves in acids without evolution of oxygen; WO_3 and MoO_3 also form double compounds with various anhydrides, *e.g.* with P_2O_5, SO_3, &c. The salt-forming character of the oxides of the family Cr, Mo, W, U, decreases from Cr to Mo, and again increases from W to U, but at the same time the extremes of the family (Cr and U) produce more distinctly marked acid-forming oxides (MO_3) than either of the means (Mo and W). Finally, the highest members of the odd and even series of Group VI., Te and U, are, on the whole, more positive (although U produces a well-marked acid-forming oxide) than the other members of either family; and the first member of the even family, viz. Cr (excepting oxygen, which belongs both to the odd and the even families), shows fairly marked analogies with the first member of the odd family, viz. S.

Summing up the characteristics of Group VI., and comparing them with those of Group II., we see that the former group, as a whole, is non-metallic; its members are comparatively negative, and their best-marked oxides, as a class, are acid-forming; but we find in it two families, one of which, Cr . . . U, is more metallic and salt-forming, and the other, S . . . Te, is more non-metallic and acid-forming. Similarly we find in Group II. two families, one more distinctly metallic than the other; but, on the other hand, the whole character of Group II. is metallic, and the oxides of the members of the group are salt-forming. In each group we have found a 'typical' element: in Group VI. oxygen, in Group II. beryllium; the properties of this element to some extent summarise the properties of all the members of the group. The difference between the value of the atomic weight of oxygen and that of the next even series member of Group VI., viz. Cr, is 36; the difference between the atomic weight of beryllium and that of the next even series member of Group II., viz. Ca, is 31; the mean difference between any two consecutive even or odd members of either group is about 45; oxygen perhaps rather more closely approaches the properties of the odd family of its group than beryllium approaches the properties of the family of Group II. the members of which belong to odd series.

Let us now turn for a moment to those groups in which the family-character preponderates over the group-character, Groups I. and VII., and to those in which the group-character is much more marked than the family-character, Groups III., IV., and V.

Group I.

Even Series—

2	4	6	8
Li=7	K=39	Rb=85	Cs=133

Odd Series—

3	5	7	9	11
Na=23	Cu=63	Ag=108	—	Au=197

The very marked similarity between Li, Na, K, Rb, and Cs, both as regards the metals themselves and their compounds, quite overshadows the much more feebly marked similarities which exist between Cu, Ag, and Au. But the thermal values of the reactions between lithium and water, between Li and O, Li and Cl, or Li and Br in presence of water, &c., the comparative insolubility of LiOH, Li_2CO_3, Li_3PO_4, the non-formation of an alum containing Li, the non-formation of double salts containing LiCl, the comparatively less ready oxidation of Li, and some other properties, show that lithium is to some extent separated from the metals Na . . . Cs. The properties of those salts of copper of which the chloride Cu_2Cl_2 is a representative, exhibit some analogies with those of the compounds of lithium. Silver approaches the even family of Group I. in the composition of all its well-marked salts, in the distinct alkalinity of its oxide, and in the fact that silver sulphate forms an alum. Although gold is distinctly marked off from the other members of the group, yet in the softness of the metal, in the facts that compounds of the form M_2O are known, that the auric haloid compounds very easily form double salts with the haloid compounds of Na . . . Cs, that Au_2O and Au_2S are sol. in water, and in a few other respects, this metal exhibits some analogies with the even family of the group and with sodium.

Group VII.

Even Series—

2	4
F=19	Mn=55

Odd Series—

3	5	7
Cl=35·5	Br=80	I=127

Here the family-character of the odd series members impresses itself on the whole group; fluorine exhibits definite relations to the odd family, but the two facts that it forms no compounds with oxygen, and that its compounds with hydrogen and the alkali metals exhibit the greatest readiness to form double salts, suffice to cut it off to some extent from Cl, Br, and I. The heat of neutralisation of HF is considerably larger than the heat of neutralisation of HCl or HBr; [HMAq, NaOHAq] = 13,740 when M = Cl or Br, but = 16,250 when M = F, but the *relative affinity* of HF is very small; it is approximately equal to 5 when that of HCl = 100, and that of HBr = 95 or so. The thermal values of some similar reactions of Cl, Br, and I, show that these elements are not so closely related to each other as a consideration of the outstanding chemical properties of their compounds would lead one to suppose; thus, [H, Cl] = 22,000; [H, Br] = 8,040; [H, I] = −6,040 (absorbed). The differences between the properties of perchloric and periodic acids also emphasise the differences between chlorine and iodine. The isomorphism of permanganates and perchlorates, the markedly acid-forming character of MnO_3, and the existence of permanganic acid, establish a connection, feeble though it be, between manganese and the other members of Group VII. In studying the relations of the members of this group it should not be forgotten that no representative of series 6, 8, 9, 10, 11, 12 or 13, is at present known.

Group III.

Even Series—

2	4	6	8	10
B=11	Sc=44	Y=89	La=139	Yb=173

Odd Series—

3	5	7	9	11
Al=27	Ga=69	In=114	—	Tl=204

The group-character is here impressed on all the elements; Al and Ga form a family to which In is allied and Tl shows analogies in one class of compounds; Sc is not without analogies to Al and Ga, it is also distinctly related to B; of the other metals too little is known to enable us clearly to see their analogies. The last member of the group, thallium, astonishes us by the marked way in which in the thallous salts (Tl_2O, Tl_2SO_4, &c.) it approaches the even series members of Group I., viz. Li . . . Cs. The typical element, boron, while showing analogies with all the other members of the group, and with other elements, *e.g.* with C and Si, is yet different from any of them; it is a good representative of the want of family likeness between the even series members or the odd series members of this group, and at the same time of the distinctly group character which is impressed on all the elements in the group.

Group IV.

Even Series—

2	4	6	8	10	12
C=12	Ti=28	Zr=90	Ce=140	—	Th=232

Odd Series—

3	5	7	9	11
Si=28	Ge=72	Sn=118	—	Pb=207

Here again the even series members do not form a family marked off from the odd series members. Certain minor families are, it is true, to be found in the group, but on the whole the group-character much preponderates. Carbon stands by itself; it is marked off from all other elements by the immense number and complexity of the compounds which it forms with H, O, N, S, and the halogens. Most nearly related to carbon we have the first odd series member of the group, silicon; the silico-organic compounds, the existence of allotropic varieties of silicon, the relations between the specific heat of silicon and temperature, the thermal values of similar reactions of carbon and silicon, exhibit the analogy between these elements (*v.* CARBON GROUP OF ELEMENTS). The physical properties of Ti and Zr, the stability, and acid-forming character, of their oxides MO_2, the volatility of their chlorides MCl_4, the isomorphism of some titanates and zirconates with silicates, these points emphasise the connections between Ti, Zr, Si, and C. But the formation of the sulphate $Ti(SO_4)_2$, of various salts of zirconium, *e.g.* $Zr(SO_4)_2$, $Zr(NO_3)_4$, &c., show that these elements incline also towards Ce and Th which follow them in the even series, and towards Sn and Pb which belong to odd series of the same group. Cerium forms salts analogous to those of zirconium, *e.g.* $Ce(SO_4)_2$, but its most marked compounds are represented by the peroxide CeO_2. Thorium again approaches more closely to Ti and Zr than Ce does; the existence of ThO_2, $Th(SO_4)_2$, K_2ThF_6, ThF_4, marks this analogy. Tin and lead resemble each other physically more than they resemble other members of the group; they exhibit the group-character in their oxides MO and MO_2, in their chlorides (or ethides) MCl_4, in their salts K_2MO_3; tin further exhibits this character in its stannic salts $Sn(SO_4)_2$, $Sn(NO_3)_4$, &c.; but each of these elements produces compounds which have no analogies among those of the other members of the group.

Group V.

Even Series—

2	4	6	8	10
N = 14	V = 51	Nb = 94	Di = 144	Ta = 182

Odd Series—

3	5	7	9	11
P = 31	As = 75	Sb = 120	Er = 166	Bi = 208

The group-character is so impressed upon the whole of these elements that we may almost say there are no families; and yet the group falls into two subdivisions, each of which nearly repeats the characteristics of the other. From N to Ta we pass from a most markedly non-metallic, acid-forming, element to an element which, on the whole, is more metallic than non-metallic; from P to Bi we repeat the same gradation, only here the starting-point is an element rather less negative in its functions than nitrogen, and the last member of the series is decidedly more positive than tantalum. The less prominently acid-forming character of phosphorus as compared with that of nitrogen is exhibited, among other ways, by the *relative affinities* of nitric and phosphoric acids; the former being taken as 100, the latter is approximately equal to 20. The balance of metallic and non-metallic properties in tantalum is well shown by the action of acids on aqueous solutions of potassium tantalate. Acids whose relative affinity is large, *e.g.* sulphuric or hydrochloric acids (affinity = (approx.) 70 and 100), decompose this salt and pp. tantalic acid (H_3TaO_4) in combination with a portion of the acid used; acids with a smaller affinity, *e.g.* sulphurous acid (affinity not determined, but, from Ostwald's electrical experiments, it must be considerably less than H_2SO_4), completely pp. pure tantalic acid; acids with yet smaller affinities, *e.g.* H_3PO_4 (affinity about 20), pp. potassium tantalate; and, lastly, acids with very small affinities, *e.g.* acetic or succinic acid (affinities 6 and 7 respectively), cause no pp. when added to solutions of potassium tantalate. That the last member of the odd series family, viz. bismuth, is more metallic than the last member of the even series family, viz. tantalum, is shown by the fact that in all its well-established compounds bismuth is positive to the other elements with which it is combined, and that if hydrated bismuthic oxide, $Bi_2O_5xH_2O$, acts as an acid it forms salts which can scarcely be obtained in definite form, and which are certainly at least partly decomposed by the action of hot water.

We have thus endeavoured to draw the outlines of a scheme of classification of the elements and their compounds based on the comparison of those which are similar in physical and chemical properties, and by similar chemical properties we have implied similarity of function and similarity of composition. It yet remains, however, to examine somewhat more closely into the composition of the compounds classified, with the view of finding whether anything can be learnt of the structure of these bodies in the sense which is given to the word structure by the molecular and atomic theory. The compositions of the highest oxides, and of some of the other compounds of the elements, appear to vary periodically with variations in the atomic weights of the elements. If R represent the mass of an element expressed by its atomic weight, and if X represent the masses of F, Cl, Br, or I, expressed by the respective atomic weights of these elements, or the masses of the groups OH, NO_3, ClO_3, &c., expressed by these formulæ, or the masses of the elements or groups of elements expressed by *halves* of the formulæ O, S, SO_4, CrO_4, &c., then we may say that the compositions of the oxides

$$R_2O,\ RO,\ R_2O_3,\ RO_2,\ R_2O_5,$$

are expressed by the symbols

$$RX,\ RX_2,\ RX_3,\ RX_4,\ RX_5.$$

We may also say that the compositions of the salts

$$R_2SO_4;\ R(NO_3)_2;\ R(NO_3)_3,\ ROCl,\ R_2(SO_4)_3,\ RONO_3;\ ROCl_3,$$

are expressed by the symbols

$$RX;\ RX_2;\ RX_3,\ RX_3,\ RX_3,\ RX_3;\ RX_5.$$

In this way it becomes possible to give general expressions for the forms of the highest stable oxides characteristic of each group, and also for the forms of the highest well-marked salts of the elements of each group. It is generally found that the greater the value of X in the oxide-form the smaller is the value of X in the salt-form. The following symbols are given by Brauner (*Sitz. W.* [*Math.-naturwiss. Classe*], 84, 1165):—

Groups .	. I.	II.	III.	IV.
Oxide forms	. RX	RX_2	RX_3	RX_4
Salt forms	. RX_7	RX_6	RX_5	RX_4
Groups .	. V.	VI.	VII.	VIII.
Oxide forms	. RX_5	RX_6	RX_7	RX_8
Salt forms	. RX_3	RX_2	RX	R_2X

The characteristic oxides of most of the elements belonging to Group I., Li . . . . Au, are represented by the general symbol R_2O; putting $X = \frac{O}{2}$, the ratio of metal to O in these oxides is expressed by the symbol RX. Similarly the composition of the characteristic oxides of the elements of Group II., Be . . . . Hg, is represented by RO; but, as $O = X_2$, the symbol RX_2 expresses the same composition as the symbol RO. The salt-forms, RX_7 . . . . RX, are interpreted in the same way as the oxide-forms. Thus Na forms a hydrated hydroxide of the composition Na.OH.3H(OH); now, if X = H = OH, this compound belongs to the general form RX_7; similarly, the salt S_2Cl_2 (Group VI.) belongs to the general form RX. These symbols must be interpreted only in a wide and general way. For instance, the highest oxide of a metal of Group I. is K_2O_4, and this belongs to the form RX_4, but the most characteristic oxides (M_2O) of the majority of the metals of this group belong to the form RX; the most characteristic oxide of copper, however, is CuO, and of gold is Au_2O_3; these oxides belong, respectively, to the forms RX_2 and RX_3. But Cu and Au are classed both in Groups I. and VIII.; the oxide form of Group VIII. is RX_8, and the salt form is R_2X; but no well-marked oxide or salt of either Cu or Au belongs to either of these forms. So again, Group V. has assigned to it the oxide form RX_5 and the salt form RX_3; the oxides N_2O_5 .... Bi_2O_5 certainly belong to the form RX_5; the salts $NO_2(OH)$, $PO_2(OH)$, &c., belong to the form RX_3; but the salts $PO(OH)_3$, $Sb_2O_3(OH)_4$, &c., belong to the form RX_5, and the salt $Bi_2O_5H(OH)$ to the form RX_6. The symbols given must then be interpreted as representing the limits between which the compositions of most of the compounds of each group vary; that with the greater value of X represents the composition of the highest compounds, and that with the smaller value of X represents the composition of the lowest compounds of the elements in any specified group. The expressions 'salt-forms' and 'oxide-forms' are not to be recommended; it would be better to summarise the facts of composition in some such way as this:—

Limiting forms between which the composition of compounds varies.

Groups.

I.	II.	III.	IV.	V.	VI.	VII.	VIII.
RX_7 to RX	RX_6 to RX_2	RX_5 to RX_3	RX_4	RX_5 to RX_3	RX_6 to RX_2	RX_7 to RX	RX_8 to R_2X

In Groups I. to III. the lower form usually represents the composition of what may be called the typical group oxides; in Groups V. to VIII. the higher form usually represents the composition of the typical group oxides. The 'typical group oxides' are not always the most stable oxides; *e.g.* $Bi_2O_5(RX_5)$ is less stable than $Bi_2O_3(RX_3)$ (Group V.), $PbO_2(RX_4)$ is less stable than $PbO(RX_2)$ (Group IV.). Sometimes these 'typical group oxides' are scarcely known to exist; *e.g.* no oxide of the form RX_7 has certainly been obtained where R is an element of Group VII.; but the composition of the highest, and speaking broadly the most stable, acids (? acids with largest affinities) of this group of acid-forming elements is represented by the symbol HMO_4 (where M = Cl, I, or Mn), and the hypothetical anhydrides of these acids have the composition M_2O_7, that is, are represented by the symbol RX_7. Of the 11 elements which ought to find places in Group VII., only 5 are actually known; when the remaining 6 have been prepared and their compounds examined some of them may be found to form oxides belonging to the form RX_7. Concerning Group VIII., it is difficult to say which oxides of the members of this group are to be taken as the typical group oxides; for Ni, Co, and Cu, one would be inclined to adopt the oxides $MO(RX_2)$, for Fe and Au the oxides $M_2O_3(RX_3)$, for silver the oxide $Ag_2O(RX)$, and for Os and Ru the oxides $MO_4(RX_8)$. The compositions of these vary between the limiting forms RX_8 and RX; there is probably a suboxide of silver (Ag_4O) belonging to the form R_2X.

When we deal with compounds other than oxides, the application of the limiting forms becomes yet more difficult. If the term salt be taken to mean (1) acids, in the cases of markedly negative elements, or (2) metallic derivatives of acids, in the cases of markedly positive elements, then the characteristic salts of the elements of Group I. are represented by Li_2SO_4, and they belong to the form RX; the characteristic salts of Group II. are represented by $BeSO_4$, and they belong to the form RX_2. Tabulating in this way the characteristic salts and their general symbols for the groups, we have the following result:—

Groups	I.	II.	III.	IV.
Salt .	Li_2SO_4	$BeSO_4$	Al_23SO_4, $B(OH)_3$	CCl_4, $Sn(SO_4)_2$
Form .	RX	RX_2	RX_3	RX_4

Group V.

Salt . . *Form* . .

$$\left.\begin{matrix} NO_2(OH),\ Bi3NO_3 \\ RX_3 \end{matrix}\right\} \text{ and } \left\{\begin{matrix} PO(OH)_3,\ SbCl_5 \\ RX_5 \end{matrix}\right.$$

Group VI.

Salt . . . . *Form* . . . .

$$\begin{matrix} Cr_23SO_4 \\ RX_3 \end{matrix} \text{ and } \left\{\begin{matrix} UCl_4,\ U(SO_4)_2 \\ RX_4 \end{matrix}\right\} \text{ and } \left\{\begin{matrix} WCl_6,\ SO_2(OH)_2 \\ RX_6 \end{matrix}\right.$$

Group VII.

Salt . . . *Form* . . .

$$\left.\begin{matrix} MnSO_4 \\ RX_2 \end{matrix}\right\} \text{ and } \left\{\begin{matrix} MnO_3(OH),\ ClO_3(OH) \\ RX_7 \end{matrix}\right.$$

Group VIII.

Salt . *Form* .

$$\left.\begin{matrix} FeSO_4 \\ RX_2 \end{matrix}\right\} \text{ and } \left\{\begin{matrix} Fe_23SO_4,\ \ AuO(OK) \\ RX_3 \end{matrix}\right\} \text{ and } \left\{\begin{matrix} PtCl_4 \\ RX_4 \end{matrix}\right\} \text{ and } \left\{\begin{matrix} OsO(OK)H(OH) \\ RX_8 \end{matrix}\right\}$$

$$\text{and } \left\{\begin{matrix} PtClSO_2(OH),\ PtPCl_5,\ PtO_22H(OH) \\ RX_8 \end{matrix}\right.$$

If the term salt is used to include all compounds of a given element, whether these be classed as double salts, basic salts, hydroxides, &c., &c., then it is easy to find representatives of most forms, intermediate between the limiting group forms, for the members of any group. For instance, salts higher than RX and up to RX_7 belonging to Group I. are represented by KI_3 (RX_3), $KAuCl_4$ and $KAuBr_4$ (RX_5), and $Na(OH).3H(OH)$ (RX_7); salts of the form RX_5 belonging to Group III. are represented by $BOCl_3$, $AlKCl_4$, and $AlKI_4$; salts belonging to Group II., of the form RX_4, are represented by $MgNaF_3$ and $BeKF_3$, and of the form RX_6 by BeK_2F_4, ZnK_2F_4, and $BaO_2H(OH)$. It has been sought to trace special relations between the forms of hydrides and hydrated oxides in each group; thus, Mendelejeff gives the following symbols:—

Groups	I.	II.	III.
Hydride form	RH_7	RH_6	RH_5
Example	—	—	—
Hydrated oxide form . .	RH_7O_4	RH_6O_4	RH_5O_4
Example	$NaOH.3HOH$	$Ca(OH)_2 2HOH$	$\frac{Al_2O_3 5H_2O}{2}$

Groups	IV.	V.	VI.	VII.
Hydride form . . .	RH_4	RH_3	RH_2	RH
Example . . .	CH_4	PH_3	OH_2	ClH
Hydrated oxide form .	RH_4O_4	RH_3O_4	RH_2O_4	RHO_4
Example . . .	$Si(OH)_4$	$PO(OH)_3$	$SO_2(OH)_2$	$ClO_3(OH)$

The limiting forms of compounds which the periodic law supplies as an aid in classifying elements and compounds are undoubtedly useful if employed with caution. The search for such limiting forms has always been carried on in chemistry. Dalton and Berzelius made it the main business of their lives, as chemists, to seek for formulæ which should express the maximum numbers of atoms of each element capable of combining together. Berzelius developed his all-embracing system of dualism on the conception that every compound is built up of two parts, themselves either simple or complex, one of which is electrically positive towards the other (*v.* Dualism). This conception at once led to that of radicles, or groups of atoms which remain so closely united throughout various chemical changes that the functions performed by them in these changes are, to all intents, the functions of single atoms. The conception of the radicle brought with it into chemistry a mode of reasoning which has been of much importance in the advances made within recent years. The group of atoms named a radicle was not known, as a rule, except as it manifested itself in the reactions of compounds supposed to be formed by the union of the radicle with other radicles or with elements. The arguments for or against an explanation of a chemical occurrence wherein radicles were regarded as taking part were necessarily based on experimental evidence which failed to bring into court the actual complex of atoms asserted to be an essential part of the mechanism of the change. Chemists became accustomed to think of certain collocations of atoms as necessary factors in this or that operation; but they attributed actual existence to these atomic groups only when mutual action and reaction was occurring between them and other groups, or single atoms. The way was thus prepared for regarding all chemical phenomena as essentially the results of mutual actions and reactions between elements or compounds, and for the conception of chemistry as the study, not so much of this kind of homogeneous matter, or that, as of the connections between the changes of composition and the changes of properties which these kinds of matters exhibit when they mutually act and react under defined conditions. The conception of radicles went hand in hand with that of types. The meaning of a typical classification of elements and compounds has been illustrated in the present article (*v.* also Radicles and Types). The most complete outcome of this method is the classification based upon the periodic law; and the use of typical forms to express the compositions of oxides, and other compounds, of each group of elements, is one of the points wherein the periodic law emphasises the continuity of chemical science.

The great objection to the use of these typical or limiting forms seems to be that they are based too exclusively on the notion of showing the composition of compounds, and that their employment tends to hide the importance of combining the study of composition with that of properties. The purely empirical compositions of the salts $KAuCl_4$ and $NaOH.3H_2O$ are certainly represented by the symbols RX_5 and RX_7, as illustrations of the existence of which forms in Group I. the salts in question are brought forward; but a comparison of the properties of these salts with those of such compounds as Au_2O_3 and Na_2O at once shows that there is a great difference between the two classes of compounds. The mere fact that platinum forms a compound which, by the dexterous use of symbols, may be represented as belonging to the type RX_8, can be of little assistance in developing a rational scheme of classification. One of the platinum compounds of this type is $PtClSO_2(OH)$; why should not this compound be used to prove that sulphur forms compounds of the type RX_8, or that chlorine forms compounds of the type RX_8? Why is the compound BeK_2F_4 (*i.e.* $BeF_2.2KF$) to be adduced as an example of the existence of compounds of the form RX_6 in Group II., and not as an example of the existence of compounds of the form RX_3 in Group I., or of the form RX in Group VII.? If empirical composition is everything, it is only necessary to write this double fluoride as K_2BeF_4, to prove that it belongs to the ($R_2X_2X_4$ that is) RX_3 form of Group I.; or as F_4BeK_2, to prove that it is an example of the ($R_4X_2X_2$ that is) RX form in Group VII.

The history of the classifications which at different times have been founded on the notion of types conclusively proves that unless attention is constantly paid to the functions, as well as to the compositions, of the bodies classified, the systems do little to further chemical advance, and the conception on which they are founded is shorn of most of its value as a science-producing idea. It is most certainly true that the classification presented by the periodic law is based on the study at once of the compositions and the functions of the bodies classified; it is this, indeed, which gives the method so marked an advantage over all others; but just because of this fact should we be ever on our guard against placing too much trust in any single part of the method, unless that part is used in conjunction with the other parts, all of which together constitute the complete method.

The forms assigned to many salts, especially to the double and basic salts, almost wholly depend on the values given to the different elementary atoms. Why do we begin by asserting that X = F, Cl, Br, I, NO_3, ClO_3, $\frac{SO_4}{2}$, $\frac{PO_4}{3}$, $\frac{O}{2}$, &c.? How is the equivalency assumed to exist between these atoms and groups of atoms actually proved to exist? In writing the equations $F = Cl = Br = NO_3 = \frac{O}{2} = \frac{SO_4}{2}$, and in applying these to the study of typical forms of salts, we are making many far-reaching assumptions. The chief assumptions are two. In the first place, the molecular theory is carried over from gases and applied without modification to liquids and solids. In the second place the tentative hypotheses which chemists have framed to help them to group together what they have learned from the study of gaseous compounds regarding the equivalency of atoms are applied to solid and liquid compounds. Both assumptions are made without acknowledging the great differences between the phenomena on which a theory of the structure of liquids and solids must rest, and the phenomena from which the prevailing theory of the structure of gases has been developed. The very word molecule is defined only in terms of gaseous phenomena. It is the study of gaseous phenomena that has obliged chemists to recognise two orders of small particles, the molecule and the atom; and it is from the study of the mutual actions of gases that a working hypothesis of the structure of molecules has been developed. In the article ATOMIC AND MOLECULAR WEIGHTS (vol. i. p. 349), an attempt has been made to show that the reacting chemical unit of a compound should at present be regarded as a collocation of atoms, which, under definite conditions, takes part in chemical changes as an individual existence. Admitting the existence of such collocations of atoms, it follows almost necessarily from every-day chemical facts that the groups have definite configurations, which remain unchanged throughout considerable changes of conditions; for all the facts of chemical change force us to regard most chemical properties as dependent on the relative arrangement, as well as on the nature and number, of the atoms which form the reacting units of compounds. There are few, if any, properties of bodies which, like weight, are the sums of the properties of the atoms, and, like the volumes occupied by gaseous compounds on the other hand, are dependent only on the state of combination of the atoms. But while we admit that the chemical properties of liquid and solid compounds are partly conditioned by the configuration of the atoms which constitute their reacting units, we cannot admit, on present evidence, that these configurations do not undergo considerable changes under the influence of other kinds of matter, or of physical agencies. We rather assert that what we know of these collocations of atoms (and what we know is as nothing compared with what we do not know) favours the view that their structure is easily changed, and that in this respect they present gradations from those which are so chemically mobile as scarcely to be recognised as definite chemical individuals, to those which are so chemically stable as almost to merit the name of molecules. If then we refuse to speculate regarding the structure of the atomic groups which seem to form the reacting units of liquid and solid compounds; and if, as a consequence of this, we also refuse to admit the validity of any arrangement of the atoms of solid and liquid compounds in order of strict equivalency—for equivalency means equal value in exchange, and the chemical equivalency of atoms can only be known when we know the functions performed by the various atoms in molecules of similar structure—can we hope to learn anything definite regarding the equivalencies of the atoms which constitute the molecules of gaseous compounds?

The subject of the equivalency of atoms goes hand in hand with that of the structure of molecules. The subject is too large to be discussed in an article on classification; but it is necessary to sketch the outlines of it as sharply as possible. All gaseous molecules formed by the union of atoms of *hydrogen*, *fluorine*, *chlorine*, *bromine*, and *iodine* are formed of two atoms; the molecules in question are these: H_2, Cl_2, Br_2, I_2, HF, HCl, HBr, HI (at very high temperatures the molecule of iodine is monatomic).

Those atoms which combine each with a single other atom to form a gaseous molecule are called monovalent atoms; the standard monovalent atoms are H, F, Cl, Br, and I. If the gaseous molecules formed by the union of atoms of H, F, Cl, Br, or I, with other atoms are tabulated, and the other atoms are then arranged in classes according as they are each found to combine with one, two, &c. atoms of H, F, Cl, Br, or I, the following arrangement results (*v.* next page). The atoms in column I. are monovalent; the atoms in column II. are called divalent, those in column III. trivalent, and so on. Atoms whose valencies are greater than one may be classed together as polyvalent. Of the 39 elements (exclusive of the 5 standard monovalent atoms) in these six columns, at least five occur each in two columns, viz. Hg, In, P, Sn, W (In probably occurs in three columns); the atoms of Ga, Cr, and Fe are probably also both divalent and trivalent.

The valency or equivalency (or quantivalence) of an elementary atom may be defined as *the number which expresses the maximum number of*

Monovalent atoms=H, F, Cl, Br, I.

Atoms which produce compound gaseous molecules by union each with

monovalent atoms (i.e. *atoms of* H, F, Cl, Br, *or* I) ***with which the given atom is found to combine to form a gaseous molecule.*** When bismuth combines with chlorine to form bismuthous chloride, one atom of the metal combines with three atoms of the halogen, and the molecule $BiCl_3$ is produced. When hydrogen combines with chlorine to form hydrochloric acid, one atom of hydrogen combines with one atom of the halogen and the molecule HCl is produced. As a single atom of Bi combines with three times as many atoms of chlorine as an atom of hydrogen combines with, an atom of bismuth is said to be equivalent to three atoms of hydrogen. In the molecule formed by the union of atoms of H and Cl, viz. HCl, there must be direct mutual action and reaction between the two atoms; in the molecule formed by the union of atoms of Bi and Cl, viz. $BiCl_3$, there may or may not be direct mutual action between the Bi atom and each of the Cl atoms. But the atom of chlorine is monovalent (*i.e.* combines with a single other atom to form a molecule), by definition, and by reason of the facts on which the definition is based; the hypothesis most in keeping with the monovalency of the chlorine atom is that each atom of chlorine in the molecule $BiCl_3$ directly acts on, and is acted on by, the atom of bismuth. Similarly, because of the existence of the molecule $SbCl_3$, the atom of Sb is said to be equivalent to three atoms of hydrogen; and, further, one atom of Sb is said to be equivalent to one atom of Bi. The conception of equivalency is here evidently that of equal value in exchange. One atom of Bi can be exchanged for one atom of Sb; one atom of O can be exchanged for one atom of Se; one atom of C can be exchanged for one atom of Si; one atom of Mo can be exchanged for one atom of W; and in each case the other parts of the molecules between which the exchange is effected remain unchanged. (The molecules in question are: $BiCl_3$ and $SbCl_3$; OH_2 and SeH_2; CCl_4 and $SiCl_4$; $MoCl_5$ and WCl_5.) The molecules concerned in the various transactions may be said, without putting too great a strain on the words, to have similar structures. But the notion of equivalency is carried further; an atom of N cannot be exchanged for an atom of In, but the molecules NH_3 and $InCl_3$ exist; assuming that 3 atoms of Cl are strictly equivalent to 3 atoms of H, it follows that an atom of N is equivalent to an atom of In. An atom of S cannot be exchanged for an atom of O in the molecule OCl_2; but the molecule SH_2 exists, therefore, on the assumption that H_2 is strictly equivalent to Cl_2; it follows that S is equivalent to O. This conclusion is upheld by the direct exchange of S for O in the molecules SH_2 and OH_2. The conception of equivalency is evidently stretched a little beyond its strict meaning when we say for instance that, because of the existence of the molecules OH_2 and $TiCl_4$, an atom of Ti is equivalent to two atoms of O. But notwithstanding this, the definition of the valency of an atom which has been given may be applied to considerations regarding the structure of molecules. So far as data go, we seem justified in widening the definition of the valency of an atom, and in asserting that this number expresses the maximum number of other atoms, be they monovalent or polyvalent, with which the given atom combines to form a gaseous molecule. Underlying the word *combines* is the conception of *direct* interaction in the molecule. It is not necessary to venture on any hypothesis as to the states of motion of the atoms which form the molecule, or as to the nature of the mutual actions which occur between them; it is only necessary to distinguish direct from indirect action.

The prevailing notions regarding the structure of molecules are based on that of the valencies of atoms; and this carries with it the conception of each atom being able to act on, and be acted on by, a limited number of other atoms. These conceptions are indicated more or less clearly in the ordinary notation. Thus the so-called structural formulæ (1)  $H_3{\equiv}C-\underset{\underset{\textstyle OH}{|}}{C}{\equiv}H_2$ and (2) $H_3{\equiv}C-O-C{\equiv}H_3$ imply, that each carbon atom in either molecule acts directly on, and is directly acted upon by, 4 other atoms (the C atom is tetravalent), that each oxygen atom acts directly on, and is directly acted on by, 2 other atoms (the O atom is divalent), and that each hydrogen atom acts directly on, and is directly acted on by, a single other atom (the H atom is monovalent). But the distribution of the interatomic reactions is represented as being different in each molecule. In the first, 5 atoms of H are represented as in direct union with (*i.e.* as directly interacting with) atoms of carbon; the sixth atom of H is represented as in indirect union (through an atom of O) with a carbon atom; the atom of O is represented as in direct union with one carbon and one hydrogen atom. In the second molecule, all the H atoms are represented as in direct union with C atoms, and there is also direct action and reaction between the atom of O and each C atom. These formulæ are arrived at after a careful study of the reactions of the compounds; they summarise these properties in the language of a special outcome of the molecular and atomic theory. It would be out of place to pursue the subject of structural formulæ here (*v.* FORMULÆ); these formulæ are supposed to rest on the fundamental conception of the valency of the atom of each element. This conception at once limits the number of atoms with which any specified atom can be directly combined in gaseous molecules; and it enables us to bring together under certain fairly definite expressions (which are, however, very easily misunderstood) regarding the composition of compounds, as composition is viewed by the molecular theory, many facts regarding the functions of compounds gained by the careful study of the behaviour of these compounds under different conditions (*v.* EQUIVALENCY).

We have already somewhat fully discussed the meaning to be given to the term acid; we have learnt that those compounds which contain replaceable hydrogen also contain negative elements. Many gaseous acids are known; the application to these of the conception of structure which springs from that of the equivalency of atoms leads to the view that in the molecule of an acid there is always direct mutual action between those atoms of hydrogen whose function is shortly expressed by the qualifying term *replaceable*, and one or more negative atoms or groups of atoms. Thus, in the molecules HCl, HBr, HI, HF, H(CN), there must be mutual action and reaction between the positive H atom and the negative Cl, Br, I, or F atom, or the negative group of atoms (CN). Again, the reactions of the molecule $C_2H_4O_2$ oblige us to admit that direct mutual action occurs between the atom of replaceable hydrogen and an atom of the negative element oxygen, and that the three atoms of hydrogen which do not act as acidic hydrogen are in direct union with carbon atoms only:

$\left(H_3\equiv C-C\!\left\langle{}^{OH}_{O}\right.\right)$.

A system of classification of compounds may be developed on the lines of the structure of the molecules of these compounds. If this classification is to be of much permanent value it must be limited to compounds to which the fundamental conceptions of the system can be applied. We have tried to show that this is equivalent to saying that the system must at present be limited to gaseous compounds. But the vast majority of chemical compounds, other than those of carbon, have not been gasified, and most of them appear to be incapable of existing in the gaseous state. Hence a system founded on the conception of molecular structure cannot be strictly applied at present to the bodies which come within the province of inorganic chemistry. Some of the subsidiary conceptions gained as the applications of the system to carbon compounds are developed may, however, be used as aids in classifying non-gasifiable bodies, provided always care be taken not to overstep the limits imposed by the conditions of the inquiry. Thus, arguing from the similarities of properties exhibited by acids as a class, and from what the hypothesis of molecular structure helps us to understand of the connections between the functions of particular atoms and the arrangement of all the atoms in the molecules of gaseous acids, we may conclude that, in the collocations of atoms which (by hypothesis) form the reacting units of non-gasifiable acids, there is more direct mutual action between the atoms of replaceable hydrogen and some negative atoms or groups of atoms, than between those atoms of replaceable hydrogen and the more positive atoms of the reacting atomic complexes. Again, when we have learned from the study of the gaseous compounds of phosphorus that an atom of this element appears to be capable of directly acting on, and being acted on by, not more than five other atoms in a molecule, we may conclude that in the collocations of atoms which (by hypothesis) form the reacting units of the non-gasifiable compounds of phosphorus, each atom of this element is probably in direct union with not more than five other atoms. This tentative conclusion may then be applied to the development of limiting forms for phosphorus compounds; the compositions of these compounds may be represented so that they shall all come under the limiting form RX_5. But it is easy to forget the limits within which such a method as this is of any real help. It is easy to forget that the notion of the equivalency of atoms, on which such a conclusion as that just reached regarding the limiting forms of phosphorus compounds is really based, is a notion which, somewhat vague in itself, becomes vaguer the moment an attempt is made to apply it to discussions about solid and liquid bodies, for which only the outlines of a molecular theory have yet been drawn.

A system of classification, even of gaseous compounds, cannot be reared on the conception of atomic valency pure and simple. If one atom can directly interact with, say, four other atoms, the existence of a vast number of molecules built up by the union of this atom with those of two or three other elements becomes possible. Why do not all these molecules exist? Because, replies the hypothesis of molecular structure, the properties, and hence the possible existence, of a molecule, depend not only on the nature, number, and actual valencies, of the constituent atoms, but also on the manner in which the mutual interatomic reactions are distributed in the molecule. Besides the valencies of the atoms, it is necessary to consider the distributions of the interactions of these atoms. But how can we frame a working hypothesis regarding the distributions of the interatomic reactions which shall help us to understand the structure of the collocations of atoms with which it seems we have to deal in liquid and solid compounds? These interatomic actions may be distributed now in this way, now in that; the effect of this or that reagent may be to cause changes in the distributions of these reactions. We have as yet no solid basis of facts, or even of intelligible hypothesis on which to build. Compounds of about fifty-six elements (excluding carbon) have been gasified; as a rule, not more than six or eight compounds of each element are known in the gaseous state; about sixty of these compounds are available as data on which to base arguments regarding the valencies of perhaps forty-five elementary atoms. Supposing, then, that a system of classification of compounds is to be based strictly on the valencies of the atoms in the molecules of these compounds, the system must be restricted to 200 or 300 compounds, formed by the combinations of about fifty-six elements.

As regards the connections between atomic valencies and atomic weights, it appears that the valencies of the elementary atoms in certain series of elements vary from a minimum value for the first member of the series to a maximum for the middle member, and back again to the minimum value for the last member of the series. Thus take series 2—Li, Be, B, C, N, O, F—the following are the valencies of the atoms of the members of this series so far as these valencies have been established on reasonably satisfactory data (the valency is in each case represented by a Roman numeral placed above the symbol of the element):—

Groups.

	I.	II.	III.	IV.	V.	VI.	VII.
Series 2—	Li^{I}	$\mathrm{Be}^{\mathrm{II}}$	$\mathrm{B}^{\mathrm{III}}$	C^{IV}	$\mathrm{N}^{\mathrm{III}}$	O^{II}	F^{I}

It is possible that the valencies of the elementary atoms vary periodically with variations in the atomic weights of the elements. Should it be established that this is so, we shall have another illustration of the wide application and usefulness of the periodic law. But the classification which is founded on the periodic law rests on this generalisation as a whole, and not on any single property of either elements or compounds. The periodic law insists on the paramount importance of the comparative study of all the properties of elements and compounds; element must be compared with element, compound with compound. Thus, and thus alone, can we hope to gain a final system of chemical classification. Thus, and thus alone, can we expect to trace the fundamental relations which undoubtedly exist between the properties and the composition, and between the changes of properties and changes of composition, of homogeneous kinds of matter. On the basis of the periodic law a scheme of classification of the chemical elements and compounds may be raised, which exhibits (1) the composition of the compounds in so far as this can be shown in the present state of chemical knowledge; (2) the functions of the compounds, that is to say the reactions in which they take part; and (3) the connections between the compositions and the functions of the compounds; and in thus classifying the compounds of the different elements the method at the same time classifies the elements themselves. M. M. P. M.

In connection with the subject-matter of this article the following articles should be read:—Atomic and molecular weights; Chemical change; Equilibrium, chemical; Equivalency; Formulæ; Molecular structure of matter, theories regarding; Periodic law; Physical methods of inquiry used in chemistry. Further details of the properties of the various families of elements and their chief compounds are given in the following articles:—Alkaline earths, metals of the (Ca Sr Ba); Alkalis, metals of the (Li Na K Rb Cs, NH_4—Tl); Boron; Carbon group of elements (C Si—Ti Zr Sn Ce Pb Th); Chromium group (Cr Mo W U); Copper group (Cu Ag, Au); [illegible]s, metals of the (Al Ga In, Sc Y La Yb—Tl); Halogens, the (F Cl Br I, CN—Mn); Hydrogen; Iron group (Fe Ni Co—Mn); Lead; Magnesium group (Be, Mg Zn Cd, Hg); Nitrogen group (N P As V Nb Sb Di Er Bi); Noble metals (Au, Rh Ru Pd, Os Ir Pt); Oxygen group (O S Se Te—Cr Mo W U); Tin group (Sn Ge Pb); Titanium group (Ti Zr Ce Th).

CLOVES, OIL OF. Contains eugenol $C_{10}H_{12}O_2$, and a terpene $C_{15}H_{24}$ (254° cor.); V.D. 7·7 (Ettling, *A.* 9, 68; Brüning, *A.* 104, 205; Williams, *A.* 107, 242; Church, *C. J.* 28, 113). The terpene is converted by Br into $C_{15}H_{22}$ (250°–260°) (Beckett a. Wright, *C. J.* 29, 1).

CNICIN $C_{42}H_{56}O_{15}$ (?). Occurs in the leaves of *Centaurea benedicta* or *Cnicus benedictus* and bitter plants of the order *Compositæ* sub-order *Cynarocephalæ* (Morin, *J. Chim. Méd.* 3, 105; Scribe, *C. R.* 15, 803). Silky needles, with bitter taste; v. sol. alcohol, v. sl. sol. ether; sl. sol. hot water. Dextro-rotatory, $[\alpha] = 131°$ (Bouchardat). Its solution is rendered turbid by long boiling. H_2SO_4 forms a blood-red solution. Conc. HClAq becomes green, and deposits a resin on warming.

COAL TAR. The oily product of the distillation of coal contains benzene, toluene, *o*-, *m*-, and *p*-, xylene, naphthalene, anthracene, phenol, *o*-, *m*-, and *p*-, cresol, and ammonia. The minor constituents are water, hydrogen, nitrogen, carbonic oxide, COS, cyanogen, CS_2, H_2S, HCN, CO_2, methane, ethylene, acetylene, propylene, allylene, butylene, crotonylene, amylene, hexylene, hexinene, ennane, decane, styrene, mesitylene, ψ-cumene, terpenes, naphthalene dihydride, methyl-naphthalene, di-methyl-naphthalene, diphenyl, acenaphthene, fluorene, phenanthrene, fluoranthene, ψ-phenanthrene, methyl-anthracene, pyrene, chrysene, picene, acetic acid, acetonitrile, thiophene, methyl-thiophene, di-methyl-thiophene, phenyl thiocarbimide, pyrocreosols, carbazole, phenyl-naphthyl-carbazole (phenylene-naphthylene-imide), xylenol, benzoic acid, (α)- and (β)-naphthol, pyridine, pyrrole, methyl-pyridine, di-methyl-pyridine, tri-methyl-pyridine, aniline, quinoline, methyl-quinoline, parvoline, coridine, rubidine, viridine, lepidine, cryptidine, and acridine (*cf.* Schultz, *Die Chemie des Steinkohlentheers*). Many of the hydrocarbons present in coal tar are probably formed from phenols by splitting off water, and reduction (Schulze, *A.* 227, 152). Others are formed by the action of heat on simpler hydrocarbons. Thus marsh gas is converted by passage through a red-hot tube into benzene, propylene, and naphthalene; ethane gives C_2H_4 and hydrogen; ethylene gives ethane and acetylene; acetylene gives hydrogen, ethane, ethylene, benzene, styrene, and naphthalene; benzene gives diphenyl and hydrogen; while a mixture of benzene and ethylene gives anthracene (Berthelot, *A.* 142, 254; Schultz, *A.* 174, 203; 203, 118). Most of the bases are probably formed either by the action of ammonia on the phenols, or by the condensation of bases so formed with themselves, with other bases, with phenols, or with unsaturated hydrocarbons.

COBALT Co. At. w. 58·8. Mol. w. unknown as element has not been gasified. [c. 1500°] (Pictet, *C. R.* 88, 1317). S.G. 8·5–8·7 (*v.* Playfair a. Joule, *C. S. Mem.* 3, 57). S.G. 8·96 (Rammelsberg, *P.* 78, 93). S.H. ·107 (Regnault, *A. Ch.* [3] 63, 5). $V_t = V_0 (1 + 3 \times \cdot00001236t)$, $t = 40°$ (Fizeau, *C. R.* 68, 1125). E.C. at 0° (Hg at 0° = 1) 9·685 (Matthiesen a. Vogt, *P. M.* [4] 26, 242). T.C. (Ag = 100) 17·2 (Barrett, *J.* 1873. 131). S.V.S. c. 6·84. H.C. $[Co^2,O^3,3H^2O] = 149,380$ (*Th.* 3, 306).

Occurrence.—The metal is found in small quantities (1 p.c.) in some meteorites. Chiefly as *smaltine*, $CoAs_2$ in which Co is more or less replaced by Ni and Fe; and *cobalt-glance*, CoAsS with Co partially replaced by Fe and Ni, Co compounds also occur as oxide, sulphate, arsenate, &c., chiefly with compounds of Ni, Fe, and Mn. Compounds of Co were used for producing blue glasses in ancient times. 'Smalt' was prepared in Saxony in the 16th century. Cobalt was first recognised as an element by Brandt in 1735. The name is said to be derived from 'Kobold' (= sprite or goblin) a term applied by miners in the middle ages to minerals which were employed in the arts, but from which no useful metal could be extracted.

Formation.—The ore is roasted to partly remove arsenic and sulphur; the residue is dissolved in HClAq with a little HNO_3; Fe is ppd. by CaO_2H_2; Cu, Bi, &c. are ppd. by H_2S; addition of bleaching powder then pps. $Co_2O_3.xH_2O$; this is heated, and the Co_3O_4 formed is reduced by heating with charcoal.

Preparation.—1. The chief impurities to be removed are As and other metals ppd. by H_2S, Fe, and Ni. The roasted ore freed from gangue may be fused with nitre, treated with water to dissolve K arsenate, the residue dissolved in *aqua regia*, evaporated, diluted, saturated with H_2S, and filtered; the filtrate may then be mixed with so much of a ferric salt that a brown pp. (ferric arsenite and $Fe_2O_6H_6$) forms on partial neutralisation, K_2CO_3Aq is then added so long as the pp. is brown, and until a few drops of the filtrate give a reddish pp. (showing ppn. of Ni) with alkali; almost every trace of As is thus removed; the filtrate may be acidulated with HCl and reppd. by H_2S. To the filtrate (which should be only slightly acid) solution of bleaching powder or NaClO is added, so long as the pp. is black (Co_3O_4), a reddish-brown colour indicates ppn. of Ni oxides; the pp. is washed, and dissolved in nitric acid, the liquid is concentrated and neutralised by KOH, mixed with KNO_2Aq, strongly acidified by acetic acid, and allowed to stand for a few days; the pp. of K-Co nitrite is washed, dried, and strongly heated; K is removed by washing with water; the residual Co oxide is dissolved in oxalic acid, and the Co oxalate is reduced by strongly heating in a closed crucible (Hermbstädt, *J. pr.* 31, 105; Patera, *J. pr.* 67, 14).—2. The oxide, prepared as described in 1, is reduced in a stream of H at temp. above 320° (Müller, *P.* 136, 51).—3. The oxide is dissolved in HClAq and the solution is evaporated to crystallisation, the crystals of $CoCl_2.6H_2O$ are dried and heated in a stream of Cl; and the $CoCl_2$ thus obtained is reduced by heating in H (Peligot, *C. R.* 19, 670).—4. A solution of the oxide is saturated with NH_4 oxalate, and the liquid is warmed, a little solid NH_4 oxalate is dissolved in the hot liquid which is then electrolysed, using a Pt basin as negative, and a piece of Pt foil as positive, electrode (Classen a. Von Reis, *B.* 14, 1622).

Properties.—Steel-grey, lustrous, crystalline plates; nearly white when polished; hard; somewhat malleable; very ductile at red heat and upwards; slightly magnetic, even at full red heat (Pouillet). The compact metal does not oxidise in air at ordinary temperatures, but when heated it forms Co_3O_4; the finely divided metal obtained by reducing the oxide or chloride in H at moderate temperatures is pyrophoric. Combines directly with Cl. Oxidised superficially by H_2O_2Aq. Decomposes steam at red heat, and NH_3 to N and H. Dissolves in mineral acids forming cobaltous salts. Cobalt wire heated till superficially oxidised, and at once plunged into fuming nitric acid, does not dissolve; it shows 'passivity' (Nicklès, *C. R.* 38, 284) due either to the formation of a protecting layer of N oxides, or to a layer of cobalt oxide (*cf. passivity of iron*, under IRON). Co in thin leaves is said to absorb H much as Pd does (Böttcher, *J.* 1874. 295).

Cobalt is distinctly metallic in its chemical behaviour; CoO forms a series of well-marked normal salts, many basic salts are also known; Co_2O_3 dissolves in acids probably forming salts, but these are very soon decomposed to cobaltous salts; double cobaltic salts are, however, stable, *e.g.* $Co(NO_2)_3.3KNO_2$ (*v.* also COBALTAMINES). When CoO is added to molten KOH, the compound $(Co_2O_3)_3.K_2O$ is said to be produced, in which Co forms part of the acid radicle (*v.* COBALTATES). The sulphides of Co show no acidic character.

The atomic weight of Co has been determined (1) from analyses of the sulphate and chloride (Marignac, *Ar. Sc.* 1, 373); (2) by reduction of CoO in H (Russell, *C. J.* [2] 1, 51); (3) by reduction of NH_4-Co cyanide and phenylammonium cobalt cyanide (Weselsky, *B.* 2, 592); (4) by reduction (by heat) of strychnine- and brucine-cobalt cyanide (Lee, *C. N.* 24, 234); (5) by reducing CoO in H (Zimmermann, *A.* 232, 324). Determinations of the S.H. have shown that 58·8 and not a multiple of this number is to be adopted. This result has been confirmed by the isomorphism of several Co salts with the corresponding salts of Ni and Fe.

Cobalt is very closely related in its chemical properties to Ni, it is classed with this metal and Fe, and it also shows analogies with Mn; *v.* IRON GROUP OF ELEMENTS.

Reactions and *Combinations.*—1. With *steam* at red heat forms CoO and H.—2. Strongly heated in *air* burns to Co_3O_4.—3. Decomposes *ammonia* at red heat to N and H.—4. Dissolves in *mineral acids* with formation of salts; with H_2SO_4 evolves SO_2, and with HNO_3 gives N oxides. Thomsen (*Th.* 3, 306) gives these thermal data; $[Co,H^2SO^4Aq]=19,710$ giving $CoSO_4+H_2$: $[Co,H^2Cl^2Aq]=16,190$.—5. Combines with *chlorine*, *bromine, and iodine*, by heating in contact with these elements, forming $CoCl_2$, $CoBr_2$, and CoI_2, respectively. $[Co,Cl^2]=76,480$; $[Co,Cl^2,Aq]=94,820$; $[Co,Br^2,Aq]=72,940$; $[Co,I^2,Aq]=42,520$ (*Th.* 3, 306).—6. Heated with *sulphur* forms CoS and Co_4S_3.—7. Combines with *selenion* to form CoSe, by heating the two elements together (*v.* COBALT, SELENIDE OF).—8. Combines with *arsenic* (*v.* COBALT, ARSENIDES OF).—9 Absorbs (? combines with) small quantities of *carbon* when strongly heated with it, forming a hard grey mass resembling steel.—10. Forms *alloys* with several metals, especially Sb, Bi, Au, Fe, Pb, Pt, Ag, Sn, and Zn; little is known of these bodies.

Detection and estimation.—Co compounds give a clear blue colour with a bead of *borax* or *microcosmic salt* in both blowpipe flames. Black CoS is ppd. by *alkaline sulphides*, but not by H_2S in acid solutions. *Ammonia* pps. blue basic salts, soluble in excess to a reddish liquid which absorbs O from the air and becomes brownish; KOHAq pps. part of the Co as hydrated oxide from this solution. Traces of Co are detected by adding excess of NH_3Aq, and then K_4FeCy_6Aq, when a dark yellowish red colour is produced (Skey, *C. N.* 15, 111); or by adding excess of KCNAq followed by NH_4 sulphide, when a blood-red colour is formed which slowly disappears (Tattersall, *C. N.* 39, 66; Papasogli, *B.* 12, 297). Co may be estimated by ppn. as oxalate, which is then decomposed by heat to metal. The Co may be separated from Ni by evaporating an acid solution to a small bulk, adding slight excess of KOHAq, acidifying with acetic acid, adding excess of a conc. solution of KNO_2 strongly acidified by acetic acid, allowing to stand for 24 hours in a warm place, and washing the ppd. $Co_2(NO_2)_6.6KNO_2$ with solution of 1 part K acetate in 9 parts H_2O. The pp. is dissolved in HClAq; liquid is evaporated until very conc. and all free acid is removed, $K_2C_2O_4Aq$ is added drop by drop until the pp. which forms is dissolved, a *little* water is added, the liquid is heated to boiling, and rather more than an equal volume of 80 p.c. acetic acid is added *very slowly*; after standing 6 hours at about 50° the ppd. Co oxalate is filtered off, washed with a mixture of equal volumes of conc. acetic acid, alcohol, and water, and dried; it is heated in a closed crucible, then strongly in the air (to oxidise C), and the oxide is reduced by strongly heating in H. After weighing, the Co should be washed in hot water and again heated in H (Classen, *Fr.* 18, 189). Classen recommends the electrolytic estimation of Co by depositing the metal from a solution in excess of warm $K_2C_2O_4Aq$ (*v.* Classen's *Quantitative Analyse durch Electrolyse*, Berlin, 1886. A description of the apparatus will be found in Dittmar's *Exercises in Quantitative Chemical Analysis*, Glasgow, 1887). Wolff (*Fr.* 18, 38) proposes to determine minute quantities of Co by a spectroscopic method based on the absorption-spectrum of very dilute solutions of Co to which excess of NH_3Aq and a little NH_4SCy have been added.

Technical applications.—By adding a fraction of a per cent. of Mg to Co an easily worked metal is obtained, which is very compact and lustrous, and resists the action of the air (Fleitmann, *B.* 12, 454; *Biedermann's Chem.-techn. Jahrber.* 1884-5. 25). Many metals may be covered with a thin deposit of Co by electrolysing a fairly conc. solution of $CoCl_2.NH_4Cl$ (Böttcher, *W. J.* 1876. 219; Gaiffe, *C. R.* 87, 100) (*v.* COBALT COLOURING MATTERS, p. 229.)

Cobalt, alloys of. Little is known of these bodies; Co seems to form alloys with Sb, Bi, Au, Fe, Pb, Pt, Ag, Sn, and Zn.

Cobalt, ammonia compounds of *v.* **COBALTAMINES, p. 222.**

Cobalt, antimonate of. $Co(SbO_3)_2.xH_2O$ (Heffter, *P.* 86, 418; *cf.* vol. i. p. 285).

Cobalt, arsenates of. $CoH_4(AsO_4)_2$ and $Co_3(AsO_4)_2.8H_2O$; *v.* vol. i. p. 308.

Cobalt, arsenides of. Co and As are said to form a grey-black, porous, mass, when heated together in the ratio of 2 parts Co to 3 parts As. The mineral *smaltine* is more or less pure Co arsenide, $CoAs_2$: and *skutterudite* is nearly pure $CoAs_3$.

Cobalt, arsenite of. $Co_3H_6(AsO_3)_4.H_2O$; *v.* vol. i. p. 306.

Cobalt, borate of. Probably $2CoB_2O_4.CoO_2H_2.3H_2O$ (H. Rose, *P.* 88, 299).

Cobalt, bromide of. $CoBr_2$. Mol. w. unknown. $[Co,Br^2,Aq] = 72,940$ (*Th.* 3, 306). A green, deliquescent, lustrous solid; prepared either by heating Co in Br vapour (Rammelsberg, *P.* 55, 244); or by warming Co in contact with Br and H_2O, evaporating over H_2SO_4, drying the crystals of $CoBr_2.6H_2O$, and heating to c. 130° (Hartley, *C. J.* [2] 12, 214). The crystals of $CoBr_2.6H_2O$ melt at 100°, giving the purple-grey hydrate $CoBr_2.2H_2O$ (Hartley). $CoBr_2$ absorbs NH_3 forming $CoBr_2.6NH_3$, from which all NH_3 can be removed by heat (*v.* COBALTAMINES). $CoBr_2Aq$ and $PtBr_4Aq$ evaporated yield carmine, rhombohedral, very deliquescent, crystals of $CoBr_2.PtBr_4.12H_2O$; S.G. 2·763 (Topsoë, *J.* 1868. 275).

Cobalt bromide, hydrated; *v.* COBALT, BROMIDE OF.

Cobalt, carbides of. Co absorbs C when heated with charcoal, forming a hard, grey, steel-like solid. It is not known whether definite carbides are formed or not.

Cobalt, chloride of, $CoCl_2$. Mol. w. unknown. $[Co,Cl^2] = 76,480$; $[CoCl^2,Aq] = 18,340$ (*Th.* 3, 306). Absorption-spectrum, *v.* Russell, *Pr.* 32, 258.

Preparation.—1. CoO, or $CoCO_3$, is dissolved in dilute HClAq, the solution is evaporated until a blue-green solid separates, which is sublimed in a stream of dry Cl or dry HCl.—2. Finely divided Co or CoS is heated in a stream of Cl.—3. $CoCl_2.6H_2O$, obtained by crystallising solution of CoO in HClAq, is heated to 120°; traces of oxychloride are always formed thus (Potilitzin, *B.* 17, 276).

Properties and Reactions.—Blue crystalline scales: easily soluble in water forming reddish liquid, also in absolute alcohol. $CoCl_2Aq$ of different S.G. contains as follows (Franz, *J. pr.* [2] 5, 274):—

S.G.	$CoCl_2$ p.c.	S.G.	$CoCl_2$ p.c.
1·0496	5	1·2245	20
1·0997	10	1·3002	25
1·1579	15	1·3613	saturated at 17·5°.

A saturated alcoholic solution contains 23·6 p.c $CoCl_2$, appears blue by reflected light and almost black by transmitted light, becomes colourless when diluted so that one part $CoCl_2$ is contained in 10,000 parts of solution, but blue colour returns on warming; S.G. of this solution is 1·0107. Addition of water to the blue alcoholic solution produces violet and then red colour; a method of determining water in alcohol or in organic compounds miscible with alcohol has been founded on this reaction (Winkler, *J. pr.* 91, 209). An aqueous solution of $CoCl_2$ becomes blue on addition of conc. HClAq, H_2SO_4, or other dehydrating agent; also on heating, the temperature of change being the lower the more conc. is the solution, thus a 50 p.c. solution changes colour at 60°-100°, a 25 p.c. solution at 85°-135°, and a 10 p.c. solution at 180°-207° (Tichborne, *J.* 1872. 27). Addition of HCl to conc. $CoCl_2Aq$ pps. crystals containing from 1 to 1½ H_2O (Ditte, *A. Ch.* [5] 22, 551). The change of colour of solution of $CoCl_2$ from blue to red is accompanied by hydration (Potilitzin, *B.* 17, 276); it is not an isomeric change as supposed by Bersch (*W. A. B.* 56, 724).

Combinations.—1. With *water* to form various hydrates (*v.* Potilitzin, *B.* 17, 276). The **hexahydrate**, $CoCl_2.6H_2O$, separates by carefully evaporating a red solution of CoO or $CoCO_3$ in HClAq; dark red monoclinic crystals; S.G. = 1·84; lose water at 30°-35°, and at 45°-50° form the dihydrate; slowly lose water over H_2SO_4 forming the dihydrate; $[CoCl^2,6H^2O] = 21,190$;

$[CoCl^2.6H^2O,Aq] = -2850$ (*Th.* 3, 306). The dihydrate, $CoCl_2.2H_2O$, forms a rose-red finely crystalline powder; prepared as described above; absorbs water from the air forming the hexahydrate. The monohydrate, $CoCl_2.H_2O$, is obtained by heating the dihydrate to c. 100°, or by slowly evaporating a solution in absolute alcohol of the hexa- or di-hydrate, the temperature being gradually raised to 95°. Lustrous, violet-blue, crystalline needles: dehydrated at 110°–120°.—2. With *ammonia* to form the compounds $M.6NH_3$, $M.4NH_3$, and $M.2NH_3$ where $M = CoCl_2$ (*v.* Cobaltamines).—3. With *ammonium chloride* to form $CoCl_2.NH_4Cl.6H_2O$; prepared by evaporating a mixture of solution of CoO in 2 parts HClAq and NH_3 in 1 part HClAq (Hantz, *A.* 66, 284); not obtained from mixed solutions of $CoCl_2$ and NH_4Cl (Merrick, *J.* 1876. 251); forms ruby-red, deliquescent crystals. — 4. With *aniline, paratoluidine*, and *xylidine*. The aniline compounds are $CoCl_2.(C_6H_5.NH_2)_2$ and $CoCl_2(C_6H_5.NH_2)_2.2C_2H_6O$; the former, lustrous blue crystals, is obtained by dissolving $CoCl_2$ in hot aniline and crystallising from absolute alcohol; the latter, rose-red leaflets, by adding aniline to an alcoholic solution of $CoCl_2$; at 100° alcohol is completely removed. The toluidine and xylidine compounds, obtained similarly to the aniline compound, are blue needles: $CoCl_2.(C_6H_4.CH_3.NH_2)_2$ and $CoCl_2.(C_6H_3(CH_3)_2.NH_2)_2$ (Lippmann a. Vortmann, *B.* 11, 1069; 12, 79).—5. With *cadmium chloride, gold chloride*, and *zinc chloride* to form $CoCl_2.2CdCl_2.12H_2O$, $CoCl_2.2AuCl_3.8H_2O$, and $CoCl_2.ZnCl_2.6H_2O$, respectively; by evaporating mixed solutions of the constituent chlorides.—6. With *cobaltous oxide*; when dilute NH_3Aq is added drop by drop to boiling $CoCl_2Aq$ a blue pp. is formed, which turns peach-red; this pp. when dried probably has the composition $2CoCl_2.6CoO.7H_2O$ (Habermann, *M.* 5, 442).

Cobalt chloride, hydrated; *v.* Cobalt, chloride of; *Combinations*, No. 1.

Cobalt, chromates of; *v.* Chromates.

Cobalt, cyanides of, also Cobalto- and Cobalticyanides; *v.* Cyanides.

Cobalt, fluoride of, $CoF_2.2H_2O$. Mol. w. unknown. Rose-red crystals; by dissolving CoO in excess of HFAq; soluble in Aq containing HF, or in a little cold water; decomposed by much hot water to oxyfluoride $Co_2OF_2.H_2O$ (Berzelius). Combines with *potassium fluoride, sodium fluoride*, and *ammonium fluoride*, to form double salts; $CoF_2.KF.H_2O$, $CoF_2.NaF.H_2O$, and $CoF_2.2NH_4F.2H_2O$ (Berzelius; Wagner, *B.* 19, 897).

Cobalt, haloid compounds of.—These compounds all belong to the form CoX_2; $X = F$, Cl, Br, or I. None has been gasified, and therefore the molecular weight of none is known with certainty. These compounds are greenish-blue solids; all form hydrates, which are reddish. All are soluble in water, and all seem to form double compounds with alkali haloid compounds. A very few oxyhaloid compounds have been prepared.

Cobalt, hydrated oxides of; *v.* Cobalt, oxides and hydroxides of.

Cobalt, hydroxides of; *v.* Cobalt, oxides and hydroxides of.

Cobalt, iodide of, CoI_2. Mol. w. unknown. A black, graphite-like, solid; obtained by digesting Co with water and iodine, filtering, evaporating the red liquid till it gets thickish, cooling over H_2SO_4, and heating the crystals to 130° (Hartley, *C. J.* [2] 12, 502). The liquid prepared as described yields green crystals of $CoI_2.2H_2O$; these are exceedingly deliquescent. When the same solution is kept at 16° or so for some days red crystals of $CoI_2.6H_2O$ separate (Hartley; Erdmann, *J. pr.* 7, 354; Rammelsberg, *P.* 48, 155). CoI_2 combines with NH_3 to form $CoI_2.4NH_3$ (Rammelsberg, *P.* 55, 245).

Cobalt, oxides and hydroxides of.—Cobalt forms three well-marked oxides: CoO, Co_3O_4, and Co_2O_3; four other oxides are known, which are usually regarded as compounds of the first and third of these, viz. $Co_2O_3.2CoO$, $Co_2O_3.3CoO$, $Co_2O_3.4CoO$, and $Co_2O_3.6CoO$. The monoxide CoO is distinctly basic; the sesquioxide Co_2O_3 dissolves in acids, probably with formation of salts, but very few salts corresponding to this oxide have been obtained as they are very easily reduced to salts of CoO; the other oxides do not form corresponding salts. The monoxide is stable when heated to a moderate temperature, but at full redness it is oxidised to Co_3O_4; Co_2O_3 is deoxidised by heating strongly with formation of Co_3O_4. Several hydrates of the various oxides are known.

I. Cobaltous oxide CoO. (*Cobalt monoxide, cobalt oxide.*) Mol. w. unknown. A greenish-brown powder, slightly hygroscopic. S.G. 5·59 to 5·75 (Playfair a. Joule, *C. S. Mem.* 3, 57). Prepared by heating $CoCO_3$ or $Co(OH)_2$ (*q. v.*) in complete absence of air (Beetz, *P.* 61, 473); or by heating $CoCl_2$ in steam (Schwarzenberg, *A.* 97, 211); or by heating Co_3O_4 in a stream of CO_2 (Russell, *C. J.* 16, 51). CoO is unchanged in air, but when strongly heated it is oxidised to Co_3O_4; it is reduced to Co by heating in H or CO, or with C; it is quickly changed to CoS by heating in H_2S.

Cobaltous hydroxide $Co(OH)_2$. (*Cobalt hydrate. Hydrated cobaltous oxide.*) $[Co,O,H^2O] = 63,400$ (*Th.* 3, 306). Obtained by adding potash to solution of a cobaltous salt in absence of air; the pp. is a blue basic salt, which slowly changes to the rose-red hydrate; the change is quickened by heating (Winkelblech, *A.* 13, 148, 253; Beetz, *P.* 61, 473). If potash is added to a boiling solution the pp. contains alkali and some basic salt (Fremy, *A.* 80, 277; 83, 227, 289). A rose-red powder; absorbs O from air turning brown; heated in absence of air gives CoO. Cobaltous oxide and hydroxide dissolve in acids forming stable cobaltous salts (*v.* Cobalt, salts of, p. 221). $[CoO^2H^2,H^2SO^4Aq] = 24,670$; $[CoO^2H^2,H^2Cl^2Aq] = 21,140$ (*Th.* 3, 307).

II. Cobaltic oxide Co_2O_3. (*Cobalt sesquioxide. Cobalt peroxide.*) Mol. w. unknown. A steel-grey, lustrous solid. Heated in air gives Co_3O_4. Dissolves in conc. acids, but very few salts have been obtained corresponding to the oxide; solution in conc. cold acetic acid gives brown pp. of $Co_2O_3.3H_2O$ with an alkali; some double salts are known, *e.g.* $Co_2(NO_2)_6.6KNO_2$ (*v.* Cobalt, salts of, p. 221). Prepared by gently-heated $Co2NO_3$ so long as reddish vapours are evolved, powdering finely and again gently heating; or by heating $Co_2O_3.3H_2O$ to 600°–700°.

Cobaltic hydroxides. The compound $Co_2(OH)_6$ or $Co_2O_3.3H_2O$ is obtained by exposing a solution of a cobaltous salt, with excess of NH_3Aq added, to the air until brown, and ppg. by KOHAq; or by ppg. a cobaltous salt solution by a hypochlorite in presence of alkali; or by passing Cl into, or adding BrAq to, $Co(OH)_2$ or $CoCO_3$ suspended in water; the pp. is dried by pressing between paper. A dark-brown powder $[Co^2,O^3,3H^2O]$ - 149,380 ; $[2CoO^2H^2,O,H^2O]$ = 22,580 (*Th.* 3, 306). By drying at 100°, or by prolonged exposure over H_2SO_4, the hydrate $Co_2O_3.2H_2O$ [? $Co_2O(OH)_4$] is obtained. The same hydrate is formed as a black lustrous deposit on the positive pole, when a slightly alkaline solution of cobaltous-potassium tartrate is electrolysed, using Pt electrodes (Wernicke, *P.* 141, 119); S.G. as thus obtained = 2·483. The hydrate $3Co_2O_3.2H_2O$ is obtained by heating $CoCl_2$ and $Co_2(NH_3)_{10}Cl_6$ in the ratio 2:1 mols., with water in a open vessel (Mills, *P.M.* [4] 35, 257).

The cobaltic hydrates lose water when gently heated, giving Co_2O_3; when strongly heated they yield Co_3O_4. They dissolve in *cold* conc. acids, forming brown solutions; these solutions are decomposed on warming and thus give cobaltous salts; the solution in conc. acetic acid is fairly stable; potash pps. $Co_2O_3.3H_2O$ from this solution. Freshly ppd. $Co_2O_3.3H_2O$ dissolves in neutral $(NH_4)_2SO_3Aq$ forming a solution of $Co_2O_3.10NH_3.6SO_2$ (Geuther, *A.* 128, 157).

III. Cobalto-cobaltic oxide Co_3O_4. (*Black oxide of Cobalt.*) Mol. w. unknown. Obtained by strongly heating in air, or in O, CoO, $Co(OH)_2$, Co_2O_3 or any of its hydrates, $CoCO_3$, $Co(NO_3)_2$, or CoC_2O_4. A black amorphous powder which slowly absorbs water from the air. S.G. 5·833–6·296 (Rammelsberg, *J.* 2, 282). Obtained as lustrous, metal-like, greyish-black microscopic octahedra, by strongly heating a mixture of $CoCl_2$ and NH_4Cl in a stream of air or O, or a mixture of CoC_2O_4 and NH_4Cl in O, and treating the residue with hot conc. HClAq. The crystals are unacted on by many conc. acids, but dissolve slowly in conc. H_2SO_4 (Schwarzenberg, *A.* 97, 211); they are non-magnetic.

Hydrates of cobalto-cobaltic oxide. Three have been described. $Co_3O_4.2H_2O$, obtained by exposing to ordinary air Co_3O_4 prepared by heating $CoCO_3$; $Co_3O_4.3H_2O$, obtained by boiling a solution of roseo-cobaltic sulphate (Genth a. Gibbs, *Am. S.* 23, 257); $Co_3O_4.7H_2O$, obtained by allowing $Co(OH)_2$ ppd. by adding excess of alkali to a cobaltous solution to stand in the air (Fremy).

IV. Other cobalto-cobaltic oxides. (i.) $Co_2O_3.2CoO$; a black powder, obtained by heating dried $CoCO_3$ to 100°–150° in a closed crucible, or by heating luteo- or purpureo-cobalt chloride with 30-40 parts water to 70°–100° in a sealed tube (Mills, *P. M.* [4] 35, 257). (ii.) $Co_2O_3.3CoO$; obtained by heating purpureo-cobalt chloride with 2 mols. $CoCl_2$ and some water to 100° in a sealed tube (Mills, *l.c.*). (iii.) $Co_2O_3.4CoO$; a black powder, unchanged by boiling with HNO_3 or H_2SO_4, obtained by strongly heating cobaltous salts in air. (iv.) $Co_2O_3.6CoO$; obtained with $6H_2O$ by adding NH_3Aq to $Co(NO_3)_2Aq$ and allowing to stand in air till pp. is yellow.

Cobalt, oxyhaloid compounds of. Very few of these compounds have been prepared. $2CoCl_2.6CoO.7H_2O$, *v.* Cobalt, chloride of; *Combinations*, No. 6. $CoF_2.CoO.H_2O$, *v.* Cobalt, fluoride of.

Cobalt, oxysulphide of, Co_2OS. (= CoO.CoS). Dark-grey powder; by heating $CoSO_4$ in H. Dilute acids dissolve CoO; conc. acids also evolve H_2S; heated, gives CoO and SO_2.

Cobalt, phosphide of, Co_2P_2. Black powder; obtained by ppg. $CoCl_2Aq$ by Na_2HPO_4Aq and heating the ppd. phosphate in a stream of H; also by heating $CoCl_2$ in PH_3. Insoluble in conc. HClAq; easily soluble in HNO_3Aq. Co and P combine, by heating Co with a mixture of P_2O_5 and charcoal.

Cobalt, salts of. *Compounds obtained by replacing the H of acids by Co.* Many of these salts are known; most of them belong to the class of *cobaltous salts* CoX_2 where X = Cl, NO_3, $\frac{SO_4}{2}$, $\frac{2}{3}PO_4$, &c.; a few double *cobaltic salts* CoX_3 are known. The Co salts are generally obtained by dissolving CoO or $CoO.H_2O$ in acids, or by double decomposition from other Co salts. Cobaltous haloid salts, sulphate, nitrate, and some others, are soluble in water; the carbonate and phosphate, &c., are insoluble. Co forms many basic salts. Aqueous solutions of cobaltous salts are generally pink; when very conc. they usually become blue to blue-green; this colour-change is accompanied by dehydration and rehydration (*cf.* Cobalt, chloride of; *Properties and Reactions*). For some account of the resemblances between Fe, Ni, and Co *v.* Iron Group of Metals. Cobaltous salts closely resemble Ni salts; many of them are also very similar to, and isomorphous with, ferrous salts. Cobaltic hydrate $Co_2O_3.3H_2O$ dissolves in conc. cold acids probably forming cobaltic salts; on warming, these solutions are generally quickly decomposed with production of cobaltous salts; a solution in acetic acid is fairly stable. When KNO_2 is added to an acetic acid solution of a cobaltous salt a pp. of the double cobaltic salt $Co(NO_2)_3.3KNO_2$ is obtained. As no compound of Co has been gasified the formulæ of the Co salts are not necessarily molecular. The chief salts of oxyacids are the *carbonates*, *nitrates*, *phosphates*, and *sulphates*; *chlorate*, *bromate*, *iodate*, *nitrite*, *phosphite*, *sulphite*, and a few others, are also known (*v.* Carbonates, nitrates, &c.). A great many double compounds of Co salts with ammonia are known (*v.* Cobaltamines, p. 222).

Cobalt, selenide of. CoSe. Co and Se combine when heated together, forming a metal-like, lustrous, greyish mass, which is fusible at red heat (Berzelius). The compound CoSe is obtained by passing vapour of Se over hot Co in an atmosphere of H; S.G. 7·65; when melted under borax it forms a yellow, crystalline, metal-like solid (Little, *A.* 112, 211).

Cobalt, sulphides of. Co and S combine directly in different proportions. Sulphides are also formed by adding alkali sulphides to cobaltous salts, and by passing H_2S into an acetic acid solution of Co_2O_3, or CoO, and in various other ways. The following sulphides are known: Co_4S_3, CoS, Co_3S_4, Co_2S_3, CoS_2; these are the simplest formulæ that can be given, but they are not necessarily molecular. The sulphides of Co are basic; CoS combines with As_2S_3 and Sb_2S_3.

I. Cobaltous sulphide CoS. (*Cobalt monosulphide.*) Occurs native as *Syepoorite.* Prepared by heating Co with S, or CoO with S, or $CoSO_4$ with BaS and excess of NaCl; forms bronze-coloured, lustrous needles, soluble in acids. Also obtained as a black amorphous powder by adding NH_4 sulphide to an aqueous solution of a cobaltous salt, or by passing H_2S into a dilute acetic acid solution of CoO, or into water holding $Co(OH)_2$ in suspension; the black pp. is soluble in dilute mineral acids, but not in acetic acid; insoluble in alkali sulphides; when moist it oxidises rapidly in air to $CoSO_4$. Non-magnetic (Hjordtdahl, *C. R.* 65, 75). Compounds of CoS with As and Sb sulphides, $M_2S_3.2CoS$, are obtained by adding Co solutions to Na thio-arsenite, &c.

II. Cobaltic sulphide Co_2S_3. (*Cobalt sesquisulphide.*) Occurs native as *Cobalt-pyrites* in octahedra. Prepared by heating CoS or $Co(OH)_2$ in a stream of H_2S, or by strongly heating a mixture of CoO, S, and KOH, and washing with water; forms a graphite-like crystalline powder. Also obtained as an amorphous black pp. by passing H_2S into a solution of Co_2O_3 in acetic acid, or by adding NH_4 sulphide to the solution of a roseo- or purpureo-cobalt salt. Insoluble in KCNAq, thus differing from NiS.

III. Cobalt disulphide CoS_2. (*Cobalt persulphide.*) *Cobalt-glance* is approximately pure $CoS_2.CoAs_2$. Obtained by moderately heating a mixture of 1 part dry CoO with 3 parts S, or of 1 part $CoCO_3$ with 1½ parts S, until excess of S has been removed (Setterberg, *P.* 7, 40). A black lustrous powder; heated in absence of air to redness forms CoS; unacted on by acids except conc. HNO_3 and *aqua regia.*

IV. Cobalto-cobaltic sulphide Co_3S_4. Occurs native as *Linnæite.* Formed, as a greenish-black powder, by heating $CoCl_2Aq$ with K polysulphide solution to 160° (Sénarmont, *A. Ch.* [3] 30, 137).

V. The sulphide Co_4S_3 is said to be obtained by heating $CoSO_4$ to whiteness in a carbon crucible, or by strongly heating Co with S, or CoO with H_2S (Hjortdahl, *C. R.* 65, 75). A grey metal-like, lustrous mass, soluble in hot HClAq with evolution of H_2S.

Cobalt, sulphocyanide of, $Co(SCy)_2$; *v.* Sulphocyanides, under Cyanides.

Cobalt, borotungstate of; *v.* Borotungstates, under Tungsten. M. M. P. M.

COBALTAMINES. (*Cobaltammonium compounds. Cobalt-ammonia compounds. Ammonio-cobalt salts. Ammoniacal cobalt bases.*) Compounds of ammonia, cobalt, and negative radicles, formed either by combination of NH_3 with cobaltous salts in absence of air, or by reactions between cobaltous salts and ammonia in presence of air.

Bergmann noticed the solubility of cobalt salts in ammonia. Tassaert (*A. Ch.* [1] 28, 95, [1799]) noted that colour-changes occur when these solutions stand in the air. Thénard (*A. Ch.* [1] 42, 211 [1803]) and Proust (*A. Ch.* [1] 60, 264 [1806]) explained these changes as caused by absorption of oxygen from the air. Quantitative measurements of the changes in question were made by L. Gmelin (*S.* 36, 236; Pfaff (*S.* 35, 486), Dingler (*B. J.* 10, 139), Hess (*P.* 26, 547), and Winkelblech (*A.* 13, 259). Beetz (*P.* 61, 489; *B. J.* 25, 169) and H. Rose (*P.* 20, 147) carried further the investigation of the compounds produced. In 1850–60 Gibbs (*P. Am. A.*; *v. post*) began his investigations of the compounds formed when ammoniacal solutions of cobalt salts are exposed to air; these researches form the basis of our knowledge of the subject. The chemists who have chiefly contributed to the elucidation of the subject of ammonio-cobalt salts, besides Gibbs, are Fremy, Claudet, Genth, Braun, Mills, Vortmann, F. Rose, and Jörgensen (references will be given to original memoirs by these and other chemists under the individual compounds).

Some cobaltous salts combine with ammonia in absence of air, forming salts which crystallise from ammoniacal solutions but are decomposed by water; these *ammonio-cobaltous salts,* or *cobalto-amines,* generally belong to the form $M.6NH_3$ where M = a cobaltous compound, *e.g.* $CoCl_2$ or $CoSO_4$. Many cobaltous salts in solution react with ammonia in presence of air to form compounds of the type $Co_2X_6.xNH_3$ where X = an acidic radicle. These *ammonio-cobaltic-salts,* or *cobalti-amines,* may be classified, primarily, according to the value of x in the general formula $Co_2X_6.xNH_3$, and secondarily according to the nature and relation to the rest of the salt of the acidic radicle X.

Recent researches have shown that when ammonia is added to a cobaltous salt solution in presence of air, the cobaltous compound probably oxidises, and at the same time combines with ammonia, and that the various ammonio-cobaltic compounds subsequently produced are derived from these oxidised compounds by removal of oxygen and ammonia, followed in some cases by recombination with more ammonia. The final production of this or that ammonio- compound seems to depend chiefly on the relative masses of the cobaltous salt and ammonia or ammonium compound originally present.

The cobaltamines form compounds with many acids and with metallic salts. The mutual relations of the various classes of cobaltamines, and the constitution of each class, are not yet thoroughly elucidated. The following classification is a fairly satisfactory scheme of arrangement, and is generally adopted:—

I. COBALTO-AMINES or AMMONIO-COBALTOUS SALTS. Formed by the reaction of cobaltous salts in solution with ammonia in absence of air. These compounds belong to the form $M.xNH_3$ where M = a cobaltous compound and x is generally = 6.

II. OXY-COBALTAMINES or AMMONIO-OXYCOBALTIC SALTS. Formed by prolonged oxidation of ammoniacal solutions of cobalt salts by a stream of air. Most of these compounds may be represented as belonging to one or other of the series $Co_2(NH_3)_{10}R_4.OH.O.OH$ and $Co_2(NH_3)_{10}R_4.O.OH$, where R = an acidic radicle Cl, Br, I, $\frac{SO_4}{2}$, $\frac{1}{3}PO_4$, &c.

III. COBALTI-AMINES or AMMONIO-COBALTIC SALTS. Formed by exposing ammo niacal solutions of cobaltous salts to the air, and adding an acid or a salt. These compounds may be divided into four main series:—

(i.) HEXAMINES or HEXAMMONIO-COBALTIC SALTS; $Co_2(NH_3)_6R^I_6$ *e.g.* $Co_2(NH_3)_6(SO_4)_3.6H_2O$. These salts are also called *dichrocobaltic salts.*

(ii.) OCTAMINES or OCTAMMONIO-COBALTIC SALTS; $Co_2(NH_3)_8R^I_6$ *e.g.* $Co_2(NH_3)_8Cl_6.2H_2O$.

(iii.) DECAMINES or DECAMMONIO-COBALTIC SALTS; $Co_2(NH_3)_{10}R^I_6$ *e.g.* $Co_2(NH_3)_{10}(OH)_6$.

(iv.) DODECAMINES or DODECAMMONIO-COBALTIC SALTS; $Co_2(NH_3)_{12}R^I_6$ *e.g.* $Co_2(NH_3)_{12}(CO_3)_3.7H_2O$. The fourth series is also called the series of *luteo-cobaltamines* or *luteo-ammonio-cobaltic salts.*

The *octamines* and *decamines* are generally divided each into three divisions:—

OCTAMINES.

(*a*) *Praseo-cobaltic salts*; normal salts, *e.g.* $Co_2(NH_3)_8(SO_4)_3.4H_2O$.

(*b*) *Fusco-cobaltic salts*; basic salts, *e.g.* $Co_2(NH_3)_8Cl_4(OH)_2.2H_2O$.

(*c*) *Croceo-cobaltic salts,* also called *nitramines of the octamine series*; derived from praseo-salts by replacing $\frac{2}{3}$ of R by NO_2 *e.g.* $Co_2(NH_3)_8SO_4(NO_2)_4$.

DECAMINES.

(*a*) *Roseo-cobaltic salts*; $Co_2(NH_3)_{10}Cl_6.2H_2O$

(*b*) *Purpureo-cobaltic salts*; $Co_2(NH_3)_{10}Cl_6$.

} differ in quantity of H_2O they contain.

(*c*) *Xantho-cobaltic salts,* also called *nitramines of the decamine series*; derived from purpureo- or roseo-salts by replacing $\frac{1}{3}$ of R by NO_2 *e.g.* $Co_2(NH_3)_{10}Cl_4(NO_2)_2.2H_2O$.

Many cobaltamines of different classes combine with acids and with metallic salts to form double compounds.

The empirical formulæ given to the cobaltamines do not sufficiently represent the properties of these compounds. It is sometimes necessary to distinguish between the functions of different radicles in the same compound; and isomerism is exhibited by some of these bodies. Thus, in the octamine series, two octamine chlorides exist, $Co_2(NH_3)_8Cl_6.2H_2O$; one is green, it loses all its water at 100°, its aqueous solution is easily decomposed giving a pp. of $Co_2O_3.3H_2O$; when the solution of this salt is treated with fairly conc. HClAq a violet salt crystallises out, having the same composition as the green salt; this violet salt does not begin to lose water at 120°, it is considerably more stable than the green salt. These two salts are representatives of two subdivisions of the division *praseo-salts*; the subdivisions are known as *octamine-praseo-salts* and *octamine-purpureo-salts* respectively. Again, in the decamine series; the chloride $Co_2(NH_3)_{10}Cl_6$ is a violet-red solid which dissolves in water, and when digested with dilute HClAq yields a red dichroic powder having the composition $Co_2(NH_3)_{10}Cl_6.2H_2O$; this salt is very unstable, it is changed to the violet-red compound on warming or on solution in water; a solution of this salt is not ppd. by $Na_4P_2O_7Aq$, while a solution of the violet-red salt is ppd. by this reagent. These two salts are representatives of two divisions of the DECAMINE SERIES, viz. the *purpureo-* and *roseo-decamines.* Some of the purpureo-salts crystallise with xH_2O, *e.g.* $Co_2(NH_3)_{10}(SO_4)_3.H_2O$; but such salts lose water without undergoing essential change, hence the water is water of crystallisation, whereas in the roseo-salts the water seems to be rather water of constitution. Again, there is a compound of the purpureo-division of the decamine series, $Co_2(NH_3)_{10}(SO_4)_2(NO_3)_2$, which is isomeric with another compound of the same division, and both are isomeric with a roseo-salt of the decamine series. So also in one of the series of oxy-cobaltamines, viz. the series $Co_2(NH_3)_{10}R_5.O.OH$, $\frac{4}{5}$ of the radicle R are more firmly held to the rest of the salt than the remaining one-fifth.

It is generally possible to give formulæ to each series, or division, which shall more or less satisfactorily represent the typical reactions of the compounds as connected with the arrangement of the different radicles, and ammonia, relatively to the cobalt atoms; but, considering the present state of knowledge of the constitution of complex mineral compounds, such formulæ have little permanent value.

In this article accounts will be given of the leading properties of each class, series, and division, of the ammonio-cobalt compounds, and descriptions will be added of the methods of preparation of one or two of the best-known members of each group; the less-known compounds will merely be recorded. For details concerning individual compounds other than those described, reference must be made to the original memoirs. (A good account of the cobaltamines will be found in the article '*Kobalt*' in Ladenburg's *Handwörterbuch der Chemie*, 5, 601 *et seq.*)

Class I.—COBALTO-AMINES or AMMONIO-COBALTOUS SALTS, $M.xNH_3$; M = cobaltous salt, x generally = 6. These salts were first examined by H. Rose (*P.* 20, 147). They are produced by combination of NH_3 with dry cobaltous salts, or adding conc. NH_3Aq to conc. solutions of cobaltous salts in absence of air; they are decomposed by heat with loss of NH_3; their aqueous solutions also undergo decomposition, especially on warming.

Ammonio-cobaltous chloride $CoCl_2.6NH_3$; obtained by adding conc. NH_3Aq to conc. $CoCl_2Aq$ until the blue pp. which forms is dissolved, in absence of air, and allowing to crystallise. Red octahedra; unchanged in a closed vessel; in the air, or over H_2SO_4, or by warming with Aq, NH_3 is separated. Soluble, without change, in dilute NH_3Aq, scarcely sol. in conc. NH_3Aq, insol. alcohol. The compound $CoCl_2.4NH_3$ is formed when NH_3 is absorbed by dry $CoCl_2$; and $CoCl_2.2NH_3$ is produced by heating $CoCl_2.6NH_3$ to 120° (H. Rose, *P.* 20, 147).

Ammonio-cobaltous nitrate $Co(NO_3)_2.6NH_3.2H_2O$; obtained similarly to the chloride. Red crystals, which quickly turn brown; decomposed by water with removal of NH_3 (Fremy, *A. Ch.* [3] 35, 257).

Ammonio-cobaltous sulphate $CoSO_4.6NH_3$; obtained by adding alcohol to an ammoniacal solution of $CoSO_4$ (Fremy), or by combination of dry $CoSO_4$ with NH_3 (Rose).

The compounds $CoBr_2.6NH_3$, $CoI_2.6NH_3$, and $CoI_2.4NH_3$ are also known (Rammelsberg, *P.* 55, 245; 48, 155).

Class II.—OXY-COBALTAMINES or AMMONIO-OXYCOBALTIC SALTS, or OXYCOBALTIAC SALTS, $Co_2(NH_3)_{10}R^I_4.OH.O.OH$, and $Co_2(NH_3)_{10}R^I_5.O.OH$, where R^I = monovalent acidic radicle. These salts are obtained by the combined action of NH_3 and air on cobaltous salts; when a stream of air is passed into an ammoniacal solution of a cobaltous salt, the colour of the liquid changes to brown, and if the solution is sufficiently conc. the oxycobaltamine frequently separates; in some cases the salt is obtained by adding a salt or an acid to the solution obtained as described. The oxycobaltamines generally partially decompose when heated alone or in NH_3Aq, giving off oxygen and forming salts of the octamine (*fusco-*) series, which, by combination with NH_3, form salts of decamine and dodecamine series. The oxycobaltamines are decomposed by warm water with ppn. of $Co_2O_3.3H_2O$ or a basic cobaltous salt and evolution of oxygen. Dilute acids partially decompose the oxycobaltamines of the form $Co_2(NH_3)_{10}R_4.OH.O.OH$ with production of green salts and separation of water. The green salts thus formed are regarded by Vortmann (*M.* 6, 404) as *anhydro-oxycobaltamines*; *e.g.* oxy-cobaltamine chloride $Co_2(NH_3)_{10}Cl_4.OH.O.OH$ with conc. HClAq gives anhydro-oxycobaltamine chloride $Co_2(NH_3)_{10}Cl_4.Cl.O.OH$, thus

$$Co_2(NH_3)_{10}Cl_4.OH.O.OH + HCl$$
$$= Co_2(NH_3)_{10}Cl_4.Cl.O.OH + H_2O.$$

The oxycobaltamines were formerly represented as containing the group Co_2O_2; and the anhydro-oxycobaltamines were regarded as acid salts derived from the oxycobaltamines (Maquenne, *C. R.* 96, 344): the change from the chloride to the anhydro-chloride, for instance, was formulated thus:—

$$Co_2O_2(NH_3)_{10}Cl_4.H_2O + HCl$$
$$= Co_2O_2(NH_3)_{10}Cl_4.ClH + H_2O.$$

But Vortmann's observation that solutions of the oxycobaltamines reduce $KMnO_4Aq$ and $K_2Cr_2O_7Aq$ points to the presence of the group O.OH; and the formation of octamine salts with evolution of ammonia and oxygen by heating ammoniacal solutions of oxy-cobaltamines confirms this supposition; thus

$$Co_2(NH_3)_{10}(NO_3)_4.OH.O.OH.H_2O$$
$$= Co_2(NH_3)_8(NO_3)_4(OH)_2 + 2NH_3 + H_2O + O.$$

Whether the green salts obtained by the reaction of acids with the oxycobaltamines are regarded as acid salts of the oxycobaltamines (Maquenne), or as anhydro-oxycobaltamines (Vortmann), in either case $\frac{1}{5}$ of the acid radicle is represented as related to the rest of the salt differently from the other four-fifths; thus the nitrate is either $Co_2(NH_3)_{10}(NO_3)_4.NO_3.O.OH$ or $Co_2O_2(NH_3)_{10}.(NO_3)_4.NO_3H$. If Vortmann's formula for the oxycobaltamines is adopted, it is better to regard the green salts as anhydro-oxy-cobaltamines. One-fifth of the acid radicle is regarded by Vortmann as directly associated with the Co atom. The existence of acid salts of the oxycobaltamines, differing in properties from the anhydro-oxycobaltamines, and very probably belonging to the same type as the oxycobaltamines (*e.g.* $Co_2(NH_3)_{10}(NO_3)_4.OH.O.OH.HNO_3$), tends to show that the green salts are better regarded as anhydro-oxycobaltamines than as acid salts of oxycobaltamines.

Series I. OXY-COBALTIAC SALTS, OR AMMONIO-OXY-COBALTIC SALTS, $Co_2(NH_3)_{10}R^I_4.OH.O.OH$.

Oxy-cobaltamine iodide $Co_2(NH_3)_{10}I_4.OH.O.OH$ (Vortmann, *M.* 6, 404); obtained by adding cold conc. KIAq to an oxidised ammoniacal solution of $CoCl_2$. Green needles; unchanged in air; decomposed by much H_2O with evolution of O. Dilute acids separate I and evolve O; hot conc. HNO_3 forms luteo-cobalt nitrate $Co_2(NH_3)_{12}(NO_3)_6$.

Oxy-cobaltamine chloride $Co_2(NH_3)_{10}Cl_4.OH.O.OH$ (Vortmann, *M.* 6, 404); obtained by dissolving crystals of $CoCl_2$ in $2\frac{1}{2}$ parts NH_3Aq S.G. ·912, with gentle warming, passing air into the cold solution until the pp. of $CoCl_2.xNH_3$, which forms, redissolves, saturating with NH_4Cl, and adding alcohol; ppn. is aided by rubbing with a glass rod. Greenish-brown powder; very unstable, easily giving off O, and then passing into fusco-cobalt chloride $Co_2(NH_3)_8.Cl_4(OH)_2$ (*cf.* Fremy, *A. Ch.* [3] 35, 257).

Oxy-cobaltamine nitrate $Co_2(NH_3)_{10}(NO_3)_4.OH.O.OH$ (Fremy, *l.c.*; Vortmann, *l.c.*; Gibbs, *P. Am. A.* 10 [1875] 1; 11, 1); obtained by leading air into saturated $Co2NO_3Aq$, to which saturated NH_4NO_3Aq, and 5 parts of NH_3Aq S.G. ·938, have been added. Dark brown prismatic crystals. Very unstable; loses water and a little NH_3 in dry air; when heated appears to form fusco-cobalt nitrate $Co_2(NH_3)_8(NO_3)_4(OH)_2$.

Oxy-cobaltamine sulphate $Co_2(NH_3)_{10}(SO_4)_2.OH.O.OH$ (Fremy; Vortmann); obtained similarly to, but more easily than, the nitrate. Dark brown crystals; more stable than the nitrate; heated to 110°–120° it loses H_2O, NH_3, and O, and forms fusco-cobalt sulphate $Co_2(NH_3)_8(SO_4)_2(OH)_2$.

Oxy-cobaltamine acid nitrate, sulphate, sulphato-chloride, &c. These salts are obtained by dissolving the nitrate or sulphate in conc. HNO_3 or H_2SO_4 respectively, or by dissolving the sulphate or nitrate in conc. HClAq. Their compositions are expressed by the formulæ

$$Co_2(NH_3)_{10}(NO_3)_4.OH.O.OH.HNO_3,$$
$$Co_2(NH_3)_{10}(SO_4)_2.OH.O.OH.2H_2SO_4,$$
$$Co_2(NH_3)_{10}(SO_4)Cl_2.OH.O.OH.4HCl,$$
$$Co_2(NH_3)_{10}(NO_3)_2Cl_2.OH.O.OH.4HCl,$$
and $$Co_2(NH_3)_{10}(SO_4)(NO_3)_2.OH.O.OH.4HNO_3.$$

These salts are all very easily decomposed by heat, giving green salts, the change probably consisting in removal of the excess of acid.

Series II. ANHYDRO-OXYCOBALTIAC SALTS, or ANHYDRO-OXY-COBALTAMINES, $Co_2(NH_3)_{10}R^I_4.R^I.O.OH$ (Vortmann, *M.* 6, 404).

Anhydro-oxy-cobaltamine chloride $Co_2(NH_3)_{10}Cl_4.Cl.O.OH.H_2O$; obtained by digesting freshly prepared oxy-cobaltamine chloride in cold conc. HClAq until the colour is green, and crystallising from warm dilute HClAq. Small green needles; stable in air; loses NH_3 and H_2O on warming; e. sol. water, the solution rapidly decomposes; when a solution in HClAq is boiled, purpureo-chloride, $Co_2(NH_3)_{10}Cl_6$, is formed; heated with NH_3Aq, purpureo-chloride is formed, along with luteo-chloride $Co_2(NH_3)_{12}Cl_6$. Forms double salts with $2PtCl_4.5H_2O$, and $3HgCl_2$.

Anhydro-oxy-cobaltamine nitrate $Co_2(NH_3)_{10}(NO_3)_4NO_3.O.OH.H_2O$; obtained by adding oxy-cobaltamine nitrate to a mixture of equal vols. conc. HNO_3 and H_2O, digesting in the cold and then warming until all is dissolved; on cooling a blue-green finely crystalline pp. forms. Sl. sol. water, solution rapidly decomposes; solution in dilute acids may be boiled without change.

The other important salts of the *anhydro-oxy-cobaltamine series* are the following:—

Sulphate $(Co_2(NH_3)_{10}.O.OH)_2(SO_4)_5.8H_2O$.

Dichromate $(Co_2(NH_3)_{10}.O.OH)_2(Cr_2O_7)_5.8H_2O$.

Chloronitrates
$Co_2(NH_3)_{10}(NO_3)_2Cl_2.Cl.O.OH.H_2O$, and
$Co_2(NH_3)_{10}(NO_3)_4Cl.O.OH.H_2O$.

Acid sulphates
$(Co_2(NH_3)_{10}.O.OH)_2(SO_4)_5.xH_2SO_4.nH_2O$; $x=1$ and 2, and $n=2$ and 3.

Acid nitrato-sulphate
$Co_2(NH_3)_{10}(SO_4)_2(NO_3).O.OH.H_2SO_4.H_2O$.

Class III.—COBALTI-AMINES, or AMMONIO-COBALTIC SALTS $Co_2(NH_3)_xR^I_6$; $x=6$, 8, 10, 12. This class comprises by far the greater number of the ammonio-cobalt salts. It is divided into four series, and some of these are again subdivided. The series are:

(i.) *Hexamines* $Co_2(NH_3)_6R_6$.
(ii.) *Octamines* $Co_2(NH_3)_8R_6$.
(iii.) *Decamines* $Co_2(NH_3)_{10}R_6$.
(iv.) *Dodecamines* $Co_2(NH_3)_{12}R_6$.

Series I. HEXAMINES, or HEXAMMONIO-COBALTIC SALTS $Co_2(NH_3)_6R^I_6$. Also called *dichro-cobaltic salts*. These salts are very unstable; they are readily decomposed by potash.

Hexamine chloride $Co_2(NH_3)_6Cl_6.H_2O$ (*Dichrocobaltic-chloride*). Octamine cobalt carbonate, $Co_2(NH_3)_8(CO_3)_3$, is obtained by dissolving $CoCO_3$ in NH_3Aq in presence of $(NH_4)_2CO_3$, exposing to air for some time, evaporating on water-bath to a small volume, adding $(NH_4)_2CO_3$ and evaporating again; this salt is dissolved in NH_3Aq, $(NH_4)_2CO_3$ is added, and the solution is evaporated to dryness on the water-bath; evaporation after addition of a little water and $(NH_4)_2CO_3$ is repeated two or three times; the crude carbonate thus obtained is treated with dilute HClAq; the turbid liquid is heated nearly to boiling, and then quickly cooled, when the hexamine chloride separates as small green crystals (Vortmann, *B.* 10, 1451; 15, 1890). Crystallises from neutral solution in green crystals, appearing almost black when large; crystallises from acidified solution in red-brown tables. Dichroïsm is best seen by evaporating a drop of solution of salt on an object-glass, and examining under microscope. Water is not completely removed at 120°. Fairly soluble in water; on warming solution becomes violet, and contains octamine purpureo-chloride $Co_2(NH_3)_8Cl_6.2H_2O$ which may be ppd. by HCl; solution in HClAq on warming gives pp. of decamine purpureo-chloride $Co_2(NH_3)_{10}Cl_6$. Forms a double salt with $HgCl_2$.

The chief salts of the *hexamine series*, besides the chloride, are the following: $M = Co_2(NH_3)_6$.

Basic carbonate $M.(OH)_2(CO_3)_2.3H_2O$.

Nitrates $M.(NO_3)_6.8H_2O$; and $M.(NO_3)_3(OH)_3.2H_2O$.

Sulphate $M.(SO_4)_3.6H_2O$.

Nitrite $M.(NO_2)_6$ (Erdmann, *J. pr.* 97, 405).

Series II. OCTAMINES, or OCTAMMONIO-COBALTIC SALTS $Co_2(NH_3)_8R^I_6$. The salts of this series are arranged in three divisions, the *praseo-*, the *fusco-*, and the *croceo- cobaltic salts.*

Division I. *Praseo-cobaltic salts.*

Praseo-cobaltic chloride $Co_2(NH_3)_8Cl_6.2H_2O$ (Vortmann, *B.* 10, 1451; 15, 1890; F. Rose, *Untersuchungen über ammoniakalische Kobaltverbindungen* [Heidelberg, 1871]). This salt exists in two modifications generally known as *praseo-cobaltic chloride* and *octamine-purpureo-cobalt chloride*, respectively. Praseo-chloride forms green lustrous crystals; e. sol. water, the solution readily decomposes, turning violet, and HCl then pps. decamine-purpureo-chloride $Co_2(NH_3)_{10}Cl_6.2H_2O$; dried at 100° this salt becomes anhydrous. Octamine-purpureo-chloride forms deep violet octahedra; does not lose any H_2O at 120°.

The praseo-salt is generally found in the mother-liquor when any cobalt salt is exposed to air in presence of ammonia, and the solution is ppd. by HCl; it is separated from such liquid by addition of NH_4Cl. The pp. is separated from admixed decamine-purpureo-chloride by washing with alcohol, drying, dissolving in conc. H_2SO_4, and carefully ppg. by HClAq added drop by drop; it is then dissolved in ice-cold water, and at once ppd. by a little HClAq.

The purpureo-salt is obtained by oxidising an ammoniacal cobalt chloride solution in the air, evaporating to a small bulk after addition of $(NH_4)_2CO_3$, filtering from ppd. luteo-chloride ($Co_2(NH_3)_{12}Cl_6$) and allowing to stand.

When a praseo-chloride solution is warmed with fairly dilute HClAq, a violet liquid is obtained, from which octamine-purpureo-chloride separates on cooling. When conc. H_2SO_4 is added to an aqueous solution of the purpureo-chloride crystals of the praseo-salt gradually separate.

Praseo-chloride forms two double salts with $HgCl_2$, viz., $M.HgCl_2$ and $M.2HgCl_2$. Purpureo-chloride forms the double salts $M.6HgCl_2.2H_2O$ and $M.3HgCl_2.H_2O$; where $M = Co_2(NH_3)_8Cl_6$. When a solution of octamine carbonate, formed as described under *hexamine chloride* (*v. supra*), is ppd. by *cold* HClAq, small red crystals are obtained; these have the composition $Co_2(NH_3)_8Cl_6.2H_2O.2H_2O$; at 120° the crystals lose $2H_2O$, becoming octamine purpureo-chloride. This salt is usually known as octamine roseo-cobalt chloride; it forms a double salt $Co_2(NH_3)_8Cl_6.2H_2O.6HgCl_2.3H_2O$.

The two salts, praseo-cobalt chloride and octamine-purpureo-chloride, are isomeric; in the second the two molecules of water are more firmly held to the rest of the salt than in the praseo- compound. The roseo-chloride differs from the two others by containing two molecules of water loosely held to the rest of the salt. Each of these salts is the representative of a subdivision of praseo-cobaltic salts; the *praseo-salts proper*, the *octamine purpureo-salts*, and the *octamine roseo-salts*. The chief salts in these subdivisions are the following:— $M = Co_2(NH_3)_8$.

Praseo-cobalt chromato-chloride $M.Cl_4.Cr_2O_7.H_2O$.

Praseo-cobalt nitrato-chloride $M.Cl_4.(NO_3)_2.2H_2O$.

Octamine purpureo-cobalt chromate $M.(CrO_4)_3.2H_2O.2H_2O$.

Octamine purpureo-cobalt sulphate $M.(SO_4)_2.2H_2O.2H_2O$.

Octamine roseo-cobalt sulphate $M.(SO_4)_2.2H_2O.4H_2O$.

Octamine cobalt carbonates $M.(CO_3)_3.3H_2O$; and $M.(CO_3)_3.H_2CO_3.2H_2O$.

Octamine cobalt sulphato-carbonate $M.(CO_3)_2SO_4.3H_2O$.

Octamine cobalt nitrate $M.(NO_3)_6.2H_2O$.

Division II. *Fusco-cobaltic salts* (Fremy, *A. Ch.* [3] 35, 257). These compounds, which are basic salts of the octamine series, are obtained from the brown liquids formed by allowing ammoniacal cobalt solutions to stand for a long time in air; they are also formed by decomposing oxy-cobaltamines by water. They are non-crystallisable; alcohol, or passage of an ammonia-stream, pps. them from their solutions. Boiled with water, especially if alkali is present, they are decomposed with separation of $Co_2O_3.3H_2O$. The chief salts are the following: $M = Co_2(NH_3)_8(OH)_2$.

Fusco-cobalt chloride $M.Cl_4.2H_2O$.

Fusco-cobalt nitrate $M.(NO_3)_4.2H_2O$.

Fusco-cobalt sulphate $M.(SO_4)_2.2H_2O$.

Division III. *Croceo-cobaltic salts.* These compounds, which are tetra-nitro-derivatives of the praseo-salts, are produced by the action of ammonia and nitrous acid (or ammonium or potassium nitrite) on solution of $Co2NO_3$ or $CoSO_4$; dark-coloured solutions are thus formed, from which the croceo-salts separate in yellow crystals mixed with $Co(OH)_2$.

Croceo-cobaltic sulphate $Co_2(NH_3)_8(NO_2)_4.SO_4$. Prepared by adding NH_3Aq and $(NH_4)NO_2$ to $CoSO_4Aq$, and recrystallising from hot dilute H_2SO_4Aq. Yellow lustrous tables; large wine-red crystals from dilute solutions. Sl. sol. hot or cold water. The other important croceo-salts are represented by the following formulæ, where $M = Co_2(NH_3)_8(NO_2)_4$: *Chloride* $M.Cl_2$; forms double salts $M.Cl_2.PtCl_4$ and $M.Cl_2.2AuCl_3$; *Bromide* $M.Br_2$; *Chromate* $M.CrO_4$; *Dichromate* $M.Cr_2O_7$; *Nitrate* $M.(NO_3)_2$; *Periodide* $M.I_2.I_4$.

Series III. DECAMINES, or DECAMMONIO-COBALTIC SALTS, $CO_2(NH_3)_{10}R^{I}_{6}$. This series contains very many compounds; these compounds are well-marked and stable bodies, frequently obtained from cobaltamines by decomposing these by acids. The series is arranged in three divisions: the roseo-, the purpureo-, and the xantho-salts. The following are typical representatives of these divisions: *roseo-cobaltic chloride* $Co_2(NH_3)_{10}Cl_6(H_2O)_2$; *purpureo-cobaltic chloride* $Co_2(NH_3)_{10}Cl_6$; *xantho-cobaltic chloride* $Co_2(NH_3)_{10}(NO_2)_2Cl_4$. The roseo- and purpureo-salts differ in the quantities of water they contain, the purpureo-salts are generally anhydrous, the roseo-salts usually contain $2H_2O$; inasmuch as these salts form very distinct compounds with different properties, it seems necessary to conclude that the $2H_2O$ of the roseo-salts is not water of crystallisation, but forms an integral part of the molecule of each of these salts. The purpureo-salts are less soluble in water than the roseo-salts; they are changed to the latter by long-continued warming in presence of water, by long-continued digestion with dilute acids at the ordinary temperature, or, generally by processes which result in hydration, but not merely by solution in water and crystallisation. The xantho-salts bear a somewhat similar relation to the purpureo-salts that the croceo-compounds of the octamine series bear to the praseo-compounds of the same series; the xantho-salts are dinitro-derivatives of the purpureo-salts, the croceo-salts are tetra-nitro-derivatives of the praseo-salts.

Division I. *Roseo-cobaltic salts.* These salts are obtained as products of the decomposition of the oxy-cobaltamines, from aqueous solutions of which they are ppd. by acids in the cold. They are obtained from purpureo-salts by long-continued digestion with dilute acids, or, more readily, by treating these salts with alkalis, *e.g.* dilute solution of NH_3 or NaOH, Ag_2O and water, or $BaCO_3$—and subsequent saturation with acids. The roseo-salts form red to peach-coloured crystals, which exhibit dichroïsm; they are fairly easily soluble in water; their ammoniacal solutions are decomposed on boiling with ppn. of $Co_2O_3.3H_2O$. These salts lose water by treatment with conc. acids, and form purpureo-salts. Roseo-salts in solution give a pp. of roseo-pyrophosphate on addition of sodium pyrophosphate; potassium ferrocyanide also gives a pp. with these salts; these reactions serve to distinguish roseo- from purpureo-salts (Jörgensen, *J. pr.* [2] 31, 49) The roseo-salts show many analogies—*e.g.* i crystalline form, methods of formation, an general reactions—with the dodecammonio- (o luteo-) salts $Co_2(NH_3)_{12}R^{I}_{6}$. Jörgensen (*J. p* [2] 31, 49) regards the roseo-decamines as luteo salts in which $2NH_3$ is replaced by $2H_2O$. Roseo chloride, nitrate, oxalate, &c., in aqueous solution react with $BaCl_2Aq$ and $Ba(NO_3)_2Aq$ to give onl roseo-salts. Roseo-chloride is soluble in 4·8 pt water at 10°, while purpureo-chloride require 287 pts. water for solution at 10°. Aqueous s lutions of the two chlorides often give differe compounds by reacting with the same re-agent *e.g.*:

With $PtCl_4$, *roseo-chloride* gives $M.Cl_6.2PtCl_4.5H_2O$; **and** *purpureo-chloride* gives $M.Cl_6.2PtCl_4$.
" $AuCl_3$ " " $M.Cl_6.2AuCl_3.2H_2O$; " " " $M.Cl_6.2AuCl_3$.
" $(NH_4)_2C_2O_4$ " " $M.(C_2O_4)_3.6H_2O$; " " " $M.Cl_2(C_2O_4)_2$.
$M = Co_2(NH_3)_{10}$.

Roseo-cobaltic chloride $Co_2(NH_3)_{10}(H_2O)_2C$ (Jörgensen, *J. pr.* [2] 18, 209; 31, 49; Gibbs Genth, *Researches on the Ammonia-cobalt bas* [Washington, 1856]; Mills, *P. M.* [4] 35, 24 Geuther, *Lehrbuch der Chemie*, 442). Obtain from an ammoniacal solution of $CoCl_2$ by oxid ing in air, or by $KMnO_4Aq$ (Mills), and p by HCl, avoiding rise of temperature; also digesting purpureo-chloride (*q. v.*) with dil HClAq, or by dissolving the same salt in NH_3 and ppg. by HCl in the cold (Jörgensen, *l.* Geuther, *l.c.*). A red, dichroïc powder, appear crystalline under the microscope. Loses 2E at 100°, giving purpureo-chloride. Soluble 4·8 pts. water at 10°. Very unstable, easily go to purpureo-chloride. Forms a gold salt, M.2Au by reaction with $AuCl_3NaCl$: forms three Pt sal $M.PtCl_6.2H_2O$, $M.2PtCl_4.H_2O$, and $M.3PtCl_4.6I$

(Jörgensen, *l.c.*): forms two Hg salts; $M.2HgCl_2$ and $M.6HgCl_2.2H_2O$ (Jörgensen, *l.c.*).

$[M = CO_2(NH_3)_{10}(OH_2)_2Cl_4.]$

Gibbs (*l.c.*) describes a *yellow form of roseo-chloride* obtained by decomposing the yellow form of roseo-sulphate (*q. v.*) by $BaCl_2Aq$; this form does not yield purpureo-chloride by reaction with HClAq.

Roseo-cobaltic sulphate $Co_2(NH_3)_{10}(H_2O)_2(SO_4)_3.3H_2O$ (Fremy, *A. Ch.* [3] 35, 257; Gibbs a. Genth, *Researches on the Ammonia-cobalt bases* [Washington, 1856]; Gibbs, *P. Am. A.* 10, 1; 11, 1; Braun, *A.* 138, 109; 142, 50; Jörgensen, *J. pr.* [2] 31, 49; 35, 417). Obtained by adding the proper quantity of H_2SO_4Aq to a solution of roseo-carbonate, and evaporating over H_2SO_4, or ppg. by alcohol; the roseo-carbonate solution is prepared by decomposing purpureo-chloride or bromide by Ag_2CO_3 (Genth, *A.* 80, 275; Claudet, *P. M.* [4] 2, 253; Jörgensen, *J. pr.* [2] 18, 209; 19, 49). Roseo-sulphate forms reddish crystals; soluble in 94·6 pts. water at 17°, and in 58 pts. water at 27°. Two other forms of the sulphate are described by Gibbs a. Genth (*P. Am. A.* 10, 1; 11, 1); they differ chiefly in solubility from the ordinary form. An *acid roseo-sulphate* $Co_2(NH_3)_{10}(OH)_2(SO_4)_3.2H_2SO_4.H_2O$ is described by Fremy (*l.c.*) (*v.* also Jörgensen, *l.c.*). The normal sulphate forms a gold and also a Pt salt: $M.(SO_4)_2Cl_2.2AuCl_3$ and $M.(SO_4)_2Cl_2.PtCl_4$ (Jörgensen, *l.c.*) $[M = Co_2(NH_3)_{10}(OH_2)_2]$.

The chief salts of the roseo- division besides the chloride and sulphate are represented by the following formulæ, where $M = Co_2(NH_3)_{10}(H_2O)_2$:— *Dichromate*, $M.(Cr_2O_7)_3.3H_2O$ (Gibbs). *Bromide*, $M.Br_6$ forming Pt salts with $2PtBr_4.2H_2O$, and $3PtBr_4.4H_2O$ (Jörgensen). *Iodide*, $M.I_6$ (Jörgensen). *Nitrate*, $M.(NO_3)_6$ (Gibbs; Jörgensen); forming a Pt salt, $M(NO_3)_2Cl_4.2PtCl_4.2H_2O$. *Nitrato-sulphate*, $M.(NO_3)_2(SO_4)_2$ (J.). *Oxalate*, $M.(C_2O_4)_3.4H_2O$. *Sulphato-oxalate*, $M.(C_2O_4)_2(SO_4).SO_4.2H_2O$ (Gibbs a. Genth). *Orthophosphates*, $M.(PO_4)_2.H_3PO_4.4H_2O$; $M.(OH)_2(PO_4H)_2.2H_2O$ (J.). *Pyrophosphates*, $M_2.(P_2O_7)_3.12H_2O$; $M.(P_2O_7H)_2$ (J.); also $M.(P_2O_7Na)_2.23H_2O$ (Gibbs, Braun, Porumbaru, *C. R.* 91, 933; 93, 342). *Bromo-sulphate*, $M.Br_2(SO_4)_2$; forms a gold salt $M.Br_2(SO_4)_2.2AuBr_3$ (J.). *Iodosulphate*, $M.I_2(SO_4)_2$ (Krok, *Acta Univers. Lund.* 1870). *Sulphite*, $M.(SO_3)_3.3H_2O$ (Gibbs); forming a double salt $M.(SO_3)_3.Co_2(SO_3)_3.9H_2O$ (Künzel, *J. pr.* 72, 209; Geuther, *l.c.*).

Division II. *Purpureo-cobaltic salts.* $Co_2(NH_3)_{10}R^I_6$. These salts are the most stable of all the cobaltamines. They are formed from the roseo-salts by heating with conc. acids, or sometimes by continued digestion with conc. acids in the cold; also by the action of acids on fusco- and xantho-cobaltic salts. The purpureo-salts are generally anhydrous; they are less soluble in water than the roseo-salts, into which salts they are changed by prolonged digestion with dilute acids. Solutions of purpureo-salts are decomposed by boiling with alkalis, giving pps. of $Co_2O_3.3H_2O$. These salts probably contain two acidic radicles more closely associated with the rest of the salt than the other four radicles; *e.g.* they form xantho-salts $Co_2(NH_3)_{10}(NO_2)_2R^I_4$; again, chloro-purpureo-sulphate $Co_2(NH_3)_{10}Cl_2(SO_4)_4$ does not give HCl with conc. H_2SO_4, nor is it ppd. by $AgNO_3Aq$ even on warming (Jörgensen). It is convenient to consider the purpureo-salts in four main sections: the *chloropurpureo-salts* $Co_2(NH_3)_{10}Cl_2.R^I_4$, the *bromopurpureo-salts* $Co_2(NH_3)_{10}Br_2.R^I_4$, the *nitrato-purpureo-salts* $Co_2(NH_3)_{10}(NO_3)_2.R^I_4$, and the *sulphato-purpureo-salts* $Co_2(NH_3)_{10}(SO_4).R^I_4$.

Chloro-purpureo-cobaltic chloride $Co_2(NH_3)_{10}Cl_2.Cl_4$ (Mills, *P. M.* [4] 35, 245; Porumbaru, *C. R.* 91, 933; 93, 342; Genth, *A.* 80, 275; Claudet, *P. M.* [4] 2, 253; Terreil, *C. R.* 62, 139; Braun, *A.* 138, 109; 142, 50). This salt is formed when an ammoniacal solution of $CoCl_2$ is allowed to oxidise in the air; boiling with excess of HClAq pps. the salt as a carmine-red powder. The reaction of HClAq or NH_4ClAq with very many cobaltamines produces this salt. Instead of oxidising $CoCl_2$ in NH_3Aq in air, which process takes a long time to accomplish, it is advisable to use $KMnO_4Aq$ (Terreil), bleaching powder (Mills), or ozonised turpentine or indigo-blue (Braun). Chloro-purpureo-chloride is a carmine-red crystalline powder; in larger crystals it appears carmine-red to black; these crystals are tetragonal pyramids, isomorphous with roseo-chloride; they are dichroïc; S.G. $\frac{23}{\,}$ 1·802; sol. 287 pts. water at 10·2°, 255 pts. at 11·5°, and 244 pts. at 15·5° (F. Rose); insol. alcohol according to Fremy (*A. Ch.* [3] 35, 257). An aqueous or alkaline, but not an acid, solution, pps. $Co_2O_3.3H_2O$ on boiling. Heated in air $CoCl_2$ and Co are obtained; at a higher temperature with free access of air Co_3O_4 is produced. Many double salts of chloropurpureo-chloride are known, *e.g.* $M.Cl_4.2PtCl_4$; $M.Cl_4.2AuCl_3$; $M.Cl_4.6HgCl_2$; $M(SiF_6)_2$ $[M = Co_2(NH_3)_{10}Cl_2]$.

The other chief salts of the *chloropurpureo-* section of purpureo-cobaltic salts are the following:—

$$M = Co_2(NH_3)_{10}Cl_2.$$

Bromide, $M.Br_4$; double salts, $M.Br_4.2PtBr_4$, $(M.Br_4)_2.9HgBr_2$.

Iodide, $M.I_4$; double salts, $M.I_4.4HgI_2$, $M.I_4.2HgI_2$.

Carbonates, $M.(CO_3)_2.9H_2O$; $M.(CO_3)_2.H_2O$.

Chromate, $M.(CrO_4)_2$ (Jörgensen, *J. pr.* [2] 18, 209).

Dichromate, $M.(Cr_2O_7)_2$ (Jörgensen).

Nitrate, $M.(NO_3)_4$ (J.).

Oxalate, $M.(C_2O_4)_2$ (J.).

Pyrophosphates, $M.(P_2O_7).xH_2O$; $M.(P_2O_7).H_4P_2O_7$ (J.); double salts, $M.(2PO_4H.5MoO_3)$, $M.(2PO_4NH_4.5MoO_3)$ (J.).

Sulphates, $M.(SO_4)_2.4H_2O$; $M.(SO_4)_2$; $M_2.(SO_4).(HSO_4)_6$ (J.).

Dithionate, $M.(S_2O_6)_2$ (J.).

Thiosulphate, $M.(S_2O_3)_2$ (J.).

Tartrate, $M.(C_4H_4O_6)_4.5H_2O$ (J.).

Bromo-purpureo-cobaltic bromide $Co_2(NH_3)_{10}Br_2.Br_4$ (Jörgensen, *J. pr.* [2] 19, 49). Obtained by oxidising ammoniacal $CoBr_2Aq$ and heating with HBrAq; or by heating roseo-sulphate with conc. HBrAq, and in other ways. Blue-violet, dichroïc, microscopic octahedra; from solutions in very dilute HBrAq separates as large black octahedra. S.G. $\frac{18}{4}$ = 2·488. Less sol. water than the chloride; 1 pt. dissolves in 530 water at 16°; insol. HBrAq, KBrAq, and alcohol, but sl. sol. in warm water acidulated with HBr, long digestion with this liquid produces roseo-bromide; decomposed to bromo-purpureo-chloride by digestion with excess of AgCl; Ag_2O or Ag_2CO_3 produces solutions of roseo-hydroxide and carbonate respectively. Forms double salts, *e.g.* $M.Br_4.6HgBr_2$; $M.(SiF_6)_2$; $M.Br_4.2PtBr_4$ [$M = Co_2(NH_3)_{10}Br_2$].

The following are the chief salts of the *bromopurpureo-* section of purpureo-cobaltic compounds:

$M = Co_2(NH_3)_{10}Br_2$.

Chloride, $M.Cl_4$; double salts, $M.Cl_4.2PtCl_4$, $M.Cl_4.6HgCl_2$ (J.).

Chromate, $M.(CrO_4)_2$ (J.).

Nitrate, $M.(NO_3)_4$ (J.).

Oxalate, $M.(C_2O_4)_2$ (J.).

Sulphate, $M.(SO_4)_2$ (J.).

Dithionate, $M.(S_2O_6)_2$ (J.).

Nitrato-purpureo-cobaltic nitrate $Co_2(NH_3)_{10}(NO_3)_2.(NO_3)_4$ (Genth, *A.* 80, 275; Fremy, *A. Ch.* [3] 35, 257; Gibbs, *Researches*, &c.; also *P. Am. A.* 10, 1; 11, 1). Obtained by dissolving $CoCO_3$ in the minimum of warm dilute HNO_3Aq, adding twice the volume of conc. NH_3Aq, boiling with addition of 127 pts. I for every 59 pts. Co used, filtering after I is all dissolved (from ppd. luteo-salt), and warming the filtrate with HNO_3Aq, whereby I is changed to HIO_3 and the nitrato-salt separates out (Jörgensen, *J. pr.* [2] 23, 227). Red powder with shade of violet; 1 pt. dissolves in 273 pts. water at 16°; decomposed by boiling with water, giving $Co_2O_3.3H_2O$. The nitrato-salts are more easily changed by hot water to roseo-salts than are the chloro- and bromo-purpureo salts. *Basic nitrates* are known; $Co_2(NH_3)_{10}(OH)_2(NO_3)_4.6H_2O$ (Gibbs); and $Co_2(NH_3)_{10}(OH)(NO_3)_5$ (Künzel, *J. pr.* 72, 209).

The following *nitrato-compounds* form the more important members of the section:

$M = Co_2(NH_3)_{10}(NO_3)_2$.

Chloride, $M.Cl_4$; double salts, $M.Cl_4.2PtCl_4$, $M.Cl_4.2HgCl_2$ (J.).

Bromide, $M.Br_4$ (J.).

Chromate, $M.(CrO_4)_2$.

Dichromate, $M.(Cr_2O_7)_2.2H_2O$ (J.).

Oxalate, $M.(C_2O_4)_2$ (J.).

Sulphate, $M.(SO_4)_2.2H_2O$ (J.).

Dithionate, $M.(S_2O_6)_2.2H_2O$ (J.).

Diamine-cobalt nitrite $M.2[Co_2(NH_3)_4(NO_2)_8]$ (J.).

Sulphato-purpureo-cobaltic sulphate $Co_2(NH_3)_{10}(SO_4).(SO_4)_2.H_2O$ (Gibbs, *P. Am. A.* 10, 1; 11, 1; Jörgensen, *J. pr.* [2] 31, 262). Obtained by adding alcohol to an oxidised ammoniacal solution of $CoSO_4$ (Gibbs), or to a 2½ p.c. aqueous solution of the acid sulphate $Co_2(NH_3)_{10}(SO_4).(SO_4[SO_4H]_2).4H_2O$ (J.). Violet-red, microscopic, dichroïc needles; v. sol. water, from which solution roseo-sulphate separates on evaporation. Forms a Pt salt, $Co_2(NH_3)_{10}(SO_4).SO_4.Cl_2.PtCl_4.2H_2O$. The chief *sulphato-salts* are the following:

$M = Co_2(NH_3)_{10}(SO_4)$.

Bromide, $M.(SO_4)Br_2$ (J.).

Nitrate, $M.(SO_4)(NO_3)_4$ (J.)

A few other purpureo-cobaltic salts are known besides those belonging to the four sections already described; the chief are

Purpureo-cobaltic iodide, $Co_2(NH_3)_{10}I_2.I_4$ (J., *J. pr.* [2] 31, 262).

Purpureo-cobaltic chromate and *dichromate*, $Co_2(NH_3)_{10}(OH)_2(CrO_4)_2$, $Co_2(NH_3)_{10}(Cr_2O_7)_3.H_2O$ (Gibbs).

Division III. *Xantho-cobaltic salts.* These salts are derived from the purpureo-compounds by replacing one-third of the acidic radicle by the group NO_2; they may be called *nitro-purpureo- salts*, $Co_2(NH_3)_{10}R_4.(NO_2)_2$. These salts are produced by the action of nitrous acid or nitrites on ammoniacal solutions of cobaltous salts, or on neutral or acid solutions of purpureo- or roseo-cobaltic salts. The xantho-salts are yellow or brownish yellow; they are more soluble in water, and more easily decomposed by water, than the other salts of the decamine series. By reacting with mineral acids they form purpureo-salts. The following are the chief xantho-salts:—

(Gibbs a. Genth, *Researches on the Ammonia-cobalt bases* [Washington, 1856]).

$M = Co_2(NH_3)_{10}(NO_2)_2$.

Chloride, $M.Cl_4$; double salts, $M.Cl_4.2AuCl_3.2H_2O$; $M.Cl_4.2PtCl_4.2H_2O$; $M.Cl_4.4HgCl_2.2H_2O$.

Iodide, $M.I_4$.

Chromate, $M.(CrO_4)_2.2H_2O$.

Dichromate, $M.(Cr_2O_7)_2$.

Oxalate, $M.(C_2O_4)_2$.

Sulphate, $M.(SO_4)_2$.

Iodo-sulphate, $M.I_2(SO_4)$.

Nitrate, $M.(NO_3)_4$.

Chloro-nitrate, $M.Cl_2(NO_3)_2$; double salts, $M.Cl_2(NO_3)_2.2AuCl_3$; $M.Cl_2(NO_3)_2.PtCl_4$.

Bromo-nitrate, $M.Br_2(NO_3)_2$.

Nitrite, $M.(NO_2)_4.4H_2O$; double salt, $M.(NO_2)_4.2(Co.(NO_2)_3)$.

Series IV. DODECAMINES, OR DODECAMMONIO-COBALTIC SALTS, OR LUTEO-COBALTIC SALTS, $Co_2(NH_3)_{12}R^I_6$. These salts are formed, along with other cobaltamines, by the oxidation of ammoniacal solutions of cobaltous compounds, especially in presence of much salammoniac; they are also produced by treating fusco-cobaltic salts with dilute acids, and by boiling roseo- or purpureo-cobaltic salts with ammonia. The luteo-salts are yellow to bronze-yellow in colour; easily crystallisable; generally more soluble in water than the corresponding roseo-salts. Acid solutions of these salts are stable; aqueous and alkaline solutions are decomposed on boiling with ppn. of $Co_2O_3.3H_2O$. Those luteo-salts which contain water of crystallisation effloresce in air or over H_2SO_4 *in vacuo*. The luteo-salts are closely analogous to the roseo-salts of the decamine series, $Co_2(NH_3)_{10}(OH_2)_2R_6$; the crystalline forms of many luteo- and roseo-salts are the same; the solubilities are similar; both series of salts give similar pps. with $K_4Fe(CN)_6Aq$ and $Na_4P_2O_7Aq$; haloid salts of both series are decomposed by Ag salts giving up the whole of their halogen. Ammonia reacts differently with the two series; the roseo-salts are dissolved with formation of basic compounds, while the luteo-salts are unchanged. Jörgensen (*J. pr.* [2] 31, 49) regards the luteo-salts as roseo- compounds in which $2H_2O$ has been replaced by $2NH_3$.

Luteo-cobaltic chloride $Co_2(NH_3)_{12}Cl_6$ (Mills, *P. M.* [4] 35, 245; Genth, *A.* 80, 275; Braun, *A.* 138, 109; 142, 50; Jörgensen, *J. pr.* [2] 35, 417). Obtained by heating an ammoniacal solution of $CoCl_2$ in presence of NH_4Cl and an oxidiser such as PbO_2, MnO_2, or $KMnO_4$; also by digesting purpureo-chloride with NH_3Aq to 50°–60° in a closed tube, and in other ways. Red-yellow, dichroïc, monoclinic crystals; S.G. 1·7016 at 20°; when dry it is unchanged in air at 130°; soluble in 16·8 parts water at 11·4° (F. Rose); crystallises from hot water on cooling; aqueous solution is ppd. by alkali chlorides, mineral acids and alcohol; unchanged by heating with conc. HClAq at 100° in a closed tube; slowly decomposed by heating with NH_3Aq, more rapidly by KOHAq. Forms various double salts of which the chief are:—$M.2AuCl_3$ (Jörgensen), $M.2PtCl_4.H_2O$, $M.PtCl_4.2H_2O$, $M.3PtCl_4.6H_2O$, $M.3PtCl_4.4H_2O$, $M.2HgCl_2$, $M.6HgCl_2.2H_2O$, $M.3SnCl_2.10H_2O$ (J.; also Braun) [$M = Co_2(NH_3)_{12}Cl_6$].

Luteo-cobaltic sulphate

$Co_2(NH_3)_{12}(SO_4)_3.5H_2O$. Obtained by passing air for some days into an ammoniacal solution of $CoSO_4$ and $CoCl_2$ mixed with NH_4Cl, treating the yellow pp. of luteo-chloride and sulphate which forms with hot water, adding Ag_2SO_4 and a few drops of H_2SO_4Aq to the solution, and crystallising by evaporation (Gibbs a. Genth, *Researches*, &c.). Also by rubbing together luteo-chloride and Ag_2O with water, filtering, acidulating the filtrate with H_2SO_4, and evaporating (Jörgensen, *J. pr.* [2] 35, 417). Yellow, rhombic, dichroïc, crystals; slightly soluble in cold, more soluble in hot, water; loses $4H_2O$ over H_2SO_4; aqueous solution is only slowly decomposed on boiling; not ppd. by acids from aqueous solution. Forms double salts with sulphates of Ce and La; $M.3LaSO_4.H_2O$, $M.3CeSO_4.H_2O$, $M.Ce_2(SO_4)_3.H_2O$ (Wing, *Am. S.* 49, 363). [$M = Co_2(NH_3)_{12}(SO_4)_3$].

The chief *luteo-salts* besides the chloride and sulphate are the following:– $M = Co_2(NH_3)_{12}$.

Carbonate, $M.(CO_3)_3.7H_2O$ (Gibbs a. Genth, *Researches*, &c.).

Chromates, $M.(CrO_4)_3.5H_2O$ (G. a. G.).

Dichromate, $M.(Cr_2O_7)_3.xH_2O$.

Bromide, $M.Br_6$; double salt, $M.Br_6.2PtBr_4.2H_2O$ (Jörgensen).

Iodide, $M.I_6$ (J.; G. a. G.).

Nitrate, $M.(NO_3)_6$; double salt, $M.(NO_3)_2.Cl_4.2PtCl_4.2H_2O$ (J.; also Fremy, *A. Ch.* [3] 35, 257).

Nitrato-sulphate, $M.(NO_3)_2.(SO_4)_2$ (J.).

Oxalate, $M.(C_2O_4)_3.4H_2O$; double salt, $M.(C_2O_4)_2.Cl_2.2AuCl_3.4H_2O$ (G. a. G.).

Phosphates, $M.(PO_4)_2.8H_2O$ (J.); $M.(PO_4H)_3.4H_2O$ (J.); $M.(P_2O_7Na)_2.23H_2O$ (J.); $M.(P_2O_7)_3.20H_2O$; $M.(P_2O_7H)_2$ (J.).

Chloro-sulphate, $M.(SO_4)_2.Cl_2$; double salts, $M.(SO_4)_2.Cl_2.2AuCl_3$, $M.(SO_4)_2.Cl_2.2HgCl_2$ (J.; G. a. G.; Schiff, *A.* 123, 1; 121, 124; Krok, *Acta Univ. Lund*, 1870).

Bromo-sulphate, $M.(SO_4)_2Br_2$ (J.); double salt, $M.(SO_4)_2.Br_2.2AuCl_3$.

Iodo-sulphate, $M.(SO_4)_2I_2$ (Krok).

Double salts of nitrite, sulphite, and dithionate, $M.(NO_2)_6.Co_2(NO_2)_6$ (Sadtler, *Am. S.* 49, 198); $M.(SO_3)_3.Co_2(SO_3)_3.2H_2O$ (Geuther, *A.* 128, 158; Künzel, *J. pr.* 72, 209); $M.(SO_3)_3.2Co_2(SO_3)_3.15H_2O$ (Geuther, Künzel); $2[M.(S_2O_6)_2.(OH)_2].Co_2(S_2O_6)_2.(OH)_2$ (G.; also K.).

COBALTAMINES NOT INCLUDED IN ANY OF THE FOREGOING CLASSES.

Erdmann's salt $Co_2(NH_3)_4(NO_2)_8K_2$ (Erdmann, *J. pr.* 97, 405). Brown, lustrous, prisms, separating from a solution of $CoCl_2$ in presence of much NH_4Cl on addition of KNO_2. Solutions of this salt give pps. of analogous compositions with solutions of many metallic salts, *e.g.* of Pb, Hg, Ag, Tl (Gibbs, *P. Am. A.* 10, 1; 11, 1).

Melano-cobaltic chloride

$Co_2(NH_3)_6.NH_2Cl.Cl_4$ (F. Rose; Vortmann, *B.* 10, 1451; 15, 1890). Greyish violet, very hygroscopic, crystals; obtained by oxidising an ammoniacal solution of a cobaltous salt, adding HClAq, filtering after an hour or so from purpureo-chloride, and dropping the filtrate into an equal volume of ice-cold fuming HClAq. This compound forms double salts, and derivatives, especially $M.Cl_4.PtCl_4$, $M.(OH)_2.Cl_2.PtCl_4$, $M.(OH)_2.Cl_2.3HgCl_2.H_2O$ (Vortmann). [$M = Co_2(NH_3)_6.NH_2Cl.$].

Ammonio-cobaltic oxychloride

$Co_2(NH_3)_2O_3Cl_2.5H_2O$ (Fremy, *A. Ch.* [3] 35, 257). Black crystals; obtained by exposing ammoniacal $CoCl_2Aq$ to the air for some months, boiling with NH_3Aq, filtering from purpureo-chloride, and boiling again. M. M. P. M.

COBALTATES. When CoO, $Co(OH)_2$, or $CoCO_3$ is dropped into 6–8 parts molten potash, a blue colour is formed which after a time changes to brown; if fusion is continued until dark-coloured crystals begin to form, the mass is then allowed to cool and treated with water, thin, black, lustrous, six-sided tablets remain. These crystals have the composition $(Co_3O_5)_3.K_2O.xH_2O$; according to Schwarzenberg $x = 3$, or if the crystals are dried at 200° $x = 1$ (*A.* 97, 212; also Mayer, *A.* 101, 266). Von Pebal (*A.* 100, 257) says that all water is removed at 100°. The crystals of *potassium cobaltate* are insoluble in water; they are decomposed at a little over 200°, water then dissolves out K_2O and Co_3O_4 remains. Mayer (*l.c.*) says that long-continued washing or boiling with water removes potash from the original crystals, and that dilute HClAq removes Co (*cf.* also Russell, *Pr.* 32, 258). M. M. P. M.

COBALTI-CYANIDES and **COBALTO-CYANIDES** *v.* CYANIDES.

COBALT COLOURING MATTERS. Addition of a Co salt to potash glass produces a deep blue colour. Roasted Co ore is fused with pearl-ash and quartz-sand, the molten mass is poured into water, and then finely powdered; it is used as a colouring matter under the name of *Smalt*. Smalt is essentially a double silicate of Co and K approaching the composition $CoO.K_2O(SiO_2)_6$. *Cobalt-ultramarine* or *Thénard's blue*, and *Cœruleum*, are essentially salts of Co chiefly phosphates and arsenates. *Cobalt-green* or *Rinman's green* contains Co and Zn oxides, and sometimes a little As_2O_3; it is prepared by evaporating mixed solutions of Co and Zn salts and strongly heating the residue. (For details of these colouring matters *v.* DICTIONARY OF TECHNICAL CHEMISTRY.) M. M. P. M.

COBRA POISON (A. Pedler, *Pr.* 27, 17; Blyth, *Analyst*, i. 204; Warden, *C. N.* 54, 197). Two-thirds of the organic matter in the poison of *Naja tripudians* is of albuminous character, being ppd. by alcohol, the poisonous substance is soluble in alcohol. NH_3 is not an antidote, but HCl retards the physiological action, while HCl and platinic chloride form a salt, $(C_{17}H_{25}N_4O_7,HCl)_2PtCl_4$(?), which is not poisonous. $AuCl_3$ and $KMnO_4$ mixed with the poison before injection prevent death; but after the poison has been injected, the subsequent injection of these liquids will not prevent death (T. L. Brunton a. Sir J. Fayrer, *Pr.* 27, 465). A poisonous crystalline substance may be obtained by dialysing the poison.

COCAÏNE $C_{17}H_{21}NO_4$. *Benzoyl-methyl-ecgonine.* [98°]. S. ·14 at 12°.

Occurrence.—In the leaves of *Erythroxylon Coca* of South America (Niemann, *Ar. Ph.* [2] 103, 120, 291; *A.* 114, 213). These leaves are chewed by the inhabitants.

Formation.—In small quantity by heating together ecgonine, benzoic anhydride and methyl-iodide at 100° for 10 hours (Merck, *B.* 18, 2952).

Preparations.—1. Coca leaves are digested with ether; the ether is evaporated and the residue extracted with boiling water; the solution is mixed with magnesia and evaporated and the cocaïne extracted by amyl alcohol (Trupheme, *C. C.* 1881, 447).—2. The leaves are extracted with alcohol, colouring matter is ppd. by lime, and the filtrate evaporated to a small bulk and mixed with water. The alkaloid is then ppd. by K_2CO_3 and dissolved in ether and decolorised by animal charcoal (Schull, *Ph.* [3] 10, 408).

Properties.—Small monoclinic prisms; $a:b:c = 1·186:1:1·223$; $\beta = 73° 50'$ (Tscherniak, *Sitz. W.* 48, i. 34); v. sl. sol. water, v. sol. hot alcohol and ether. Conc. H_2SO_4 dissolves it without colour. It produces insensibility to pain in the tongue, eye, or other part touched by it. Taken internally it acts somewhat like opium (Kennedy, *Ph.* [3] 10, 65; J. Grasset, *C. R.* 99, 983, 1122; 100, 364; Richard, *C. R.* 100, 1409; Laffont, *C. R.* 105, 1278; Sighicelli, *C. C.* 1887, 1150). An injection of cocaïne acts as a cerebro-spinal stimulant or anti-narcotic (Mosso, *Ar. Ph.* [3] 26, 179). Solutions of salts of cocaïne are ppd. by KOH, NH_3, and Na_2CO_3; the pp. is soluble only in a large excess of KOH, but insol. NH_3. Ammonium carbonate gives a pp. sol. excess. Picric acid, tannin and HCl, potassio-mercuric iodide, iodine solution, $SnCl_2$, $AuCl_3$, and $PtCl_4$ also give pps. By heating with conc. HCl cocaine is split up into ecgonine $C_9H_{15}NO_3$, methyl alcohol, and benzoic acid (Lossen, *A.* 133, 351). Cocaïne, freshly ppd. by NH_3 and left under water, slowly decomposes forming MeOH and benzoyl-ecgonine (Paul, *Ph.* [3] 18, 783). The specific rotation in chloroform solution at 20° is given by the formula: $[\alpha]_D = -(15·827 + ·00585\,q)$, where q = weight of chloroform in 100 pts. by weight of the solution, and the tube is 100 mm. long. If $q = 0$ then $[\alpha]_D = -15·827$.

Salts.—B'HCl: the melting-point varies in different preparations between [181°] and [185°]. For its medicinal employment its absolute purity is essential, and this is best determined by taking its specific rotation. In dilute alcoholic solution at 20°, with a tube 100 mm. long, the specific rotation is given by the formula: $[\alpha]_D = -(52·18 + ·1588\,q)$, and $[\alpha]_D = -(67·982 - ·15827\,c)$, where q = weight of dilute alcohol of S.G. $\frac{20}{4}$ ·9358 (mixture of 6 pts. by weight of absol. alcohol to 9 pts. by weight of water) in 100 pts. by weight of the solution, and c = weight of cocaïne hydrochloride in 100 pts. by vol. of the solution. When $q = 0$, then $[\alpha]_D = 52·2$; when $q = 100$, then $[\alpha]_D = 68·0$ (Antrick, *B.* 20, 310).—$B'_2H_2PtCl_6$.—$B'HAuCl_4$.—$B'H_2C_2O_4$: feathery crystals.

Amorphous cocaïne. An amorphous alkaloid accompanies cocaïne in coca-leaves. It is v. sol. alcohol and ether. Its hydrochloride is amorphous, and its solution partially decomposes on evaporation, becoming acid (Paul, *Ph.* [3] 18, 784). According to Hesse (*Ph.* [3] 18, 71) this base is isomeric with cocaïne (*cf.* Stockman, *Ph.* [3] 17, 861; Howard, *Ph.* [3] 18, 71; Bender, *C. C.* 1885, 490. *V. also* ECGONINE).

COCATANNIC ACID $C_{14}H_{18}O_8$. [189°]. Occurs in coca leaves (Warden, *Ph.* [3] 18, 985). Gives a red colour with KOH. $FeSO_4$ and Fe_2Cl_6 give a dark-green colour. $Pb(OAc)_2$ gives a rose-red pp. It reduces alkaline silver solution, but not Fehling's solution. Potash-fusion gives butyric and traces of benzoic acids.

COCCERIC ACID $C_{31}H_{62}O_3$. [93°]. Formed, together with cocceryl alcohol, by saponification of coccerin, the wax of cochineal. White crystalline powder. Sol. hot alcohol, ether, benzene, &c., sl. sol. the cold solvents. On oxidation with CrO_3 and acetic acid it gives pentadecoic acid, the same product as from cocceryl alcohol (Liebermann a. Bergami, *B.* 20, 964).—A'_2Ca and A'_2Ba: flocculent pps.

Ethyl ether A'Et. [c. 70°] (Liebermann, *B.* 18, 1980).

COCCERIN $C_{30}H_{60}(O.C_{31}H_{61}O_2)_2$. *Cocceryl coccerate.* [106°]. Occurs in cochineal in quantity varying from 1 p.c. to 4 p.c. and is obtained by extraction with benzene. The cocoons of the cochineal insect consist of coccerin to the extent of $\frac{3}{4}$ of their weight (Liebermann, *B.* 19, 328). Thin glistening plates. Sl. sol. all cold solvents, nearly insol. alcohol and ether. On saponification with alcoholic KOH it gives cocceryl alcohol $C_{30}H_{60}(OH)_2$ and cocceric acid $C_{31}H_{62}O_3$ (Liebermann, *B.* 18, 1975).

COCCERYL ALCOHOL $C_{30}H_{60}(OH)_2$. [101°–104°]. Formed, together with cocceric acid, by saponification of coccerin, the wax of cochineal (Liebermann, *B.* 18, 1975). White crystalline powder. On oxidation with CrO_3 and acetic acid it gives pentadecoic acid $C_{15}H_{30}O_2$ and probably also an acid $C_{30}H_{60}O_3$.

Acetyl derivative $C_{30}H_{60}(OAc)_2$: [50°]; crystalline solid; v. sol. ether, warm alcohol, and acetic acid; v. sl. sol. acetone.

Benzoyl derivative $C_{30}H_{60}(OBz)_2$: [62°]; crystalline solid; v. sol. ether, warm alcohol, and acetic acid, v. sl. sol. acetone (Liebermann a. Bergami, *B.* 20, 959).

COCCININ *v.* CARMINIC ACID.

COCCOGNIN $C_{20}H_{22}O_8$. A crystalline substance occurring in the seeds of *Daphne Mezereum.* Sl. sol. water, v. sol. alcohol and ether. May be sublimed, when it emits an odour like coumarin. Boiling dilute H_2SO_4 forms no glucose from it (Casselmann, *Z.* [2] 6, 681).

COCCULIN $C_{19}H_{26}O_{10}$. Occurs in cocculus indicus. Found in small quantities in the preparation of picrotoxin (*q.v.*), from which it can be separated by means of absolute alcohol, and recrystallised from hot water acidulated with HCl. Conc. H_2SO_4 colours it pale yellow, disappearing on stirring (Löwenhardt, *A.* 222, 353).

COCETHYLINE $C_{18}H_{23}NO_4$. [109°]. Obtained by heating benzoyl-ecgonine with ethyl iodide for 8 hours at 100°. Splendid glistening prisms. Has an anæsthetic action. $PtCl_4$ gives with very dilute solutions of the hydrochloride a yellow pp. of the platino-chloride $B'_{12}H_2Cl_2PtCl_4$, which crystallises from a large quantity of hot water in glittering yellow rhombic plates. $AuCl_3$ gives a very sparingly soluble yellow pp. $HgCl_2$ forms a white pp., v. sol. hot water (Merck, *B.* 18, 2954).

COCHLEARIA OIL. The essential oil of scurvy-grass (*Cochlearia officinalis*) is isobutyl thiocarbimide (Hofmann, *B.* 7, 508).

COCOA NUT OIL *or cocoa butter.* The following acids have been described as present in the product of saponification of this fatty oil: hexoic, octoic, decoic, lauric $C_{12}H_{24}O_2$, an isomeride of lauric [58°], tridecoic $C_{13}H_{26}O_2$, myristic, palmitic, stearic, oleic, and arachic acids. Kingzett (*C. J.* 33, 38) also found an acid $C_{64}H_{128}O_2$ [72°] (Bromeis, *A.* 35, 86; Fehling, *A.* 53, 399; Gœrgey, *A.* 66, 290; Oudemans, *J. pr.* 81, 367; Carr Robinson, *Tr. E.* 28, 277; Traub, *Ar. Ph.* [3] 21, 19).

CODAMINE $C_{20}H_{25}NO_4$. [126°] (from benzene); [121°] (from alcohol or ether). An alkaloid occurring in the aqueous extract of opium (Hesse, *A.* 153, 56; *Suppl.* 8, 280). Six-sided prisms (from ether); m. sol. boiling water, v. sol. benzene, alcohol, chloroform, and ether. Conc. HNO_3 gives a green solution. Fe_2Cl_6Aq gives a green colour. Conc. H_2SO_4 gives a blue colour, changing to green, and to dark violet on warming. NH_3 and KOH give pps. sol. excess.—$B'_2H_2PtCl_6$ 2aq. B'HI 1½aq.

CODEÏNE $C_{18}H_{21}NO_3$. *Methyl-morphine. Codeia.* [150°]. S.G. 1·32. S. 1·26 at 15°, 5·88 at 100°. $[\alpha]_D = -134°$ (in alcohol). S. (amyl alcohol) 15·68; S. (benzene) 9·60 (Kubly, *J.* 1866, 823).

Synthesis.—By gently heating morphine (1 mol.) with NaOH (1 mol.) and MeI (1 mol.) dissolved in alcohol (Grimaux, *C. R.* 92, 1140, 1228; Hesse, *A.* 222, 210). The yield is small, but by doubling the quantity of MeI a good yield of codeïne methylo-iodide may be obtained. The codeïne so prepared is lævorotatory; $[\alpha]_D = -130°$.

Preparation.—Aqueous extract of opium is freed from meconic acid by ppg. with $CaCl_2$, and the filtrate evaporated to crystallisation. The mixed hydrochlorides of morphine and codeïne are dissolved in water and ppd. by ammonia; morphine is ppd. but codeïne remains in solution. On evaporating the filtrate codeïne hydrochloride crystallises out (Robiquet, *A. Ch.* [2] 51, 259; *A.* 5, 106; Gregory, *A.* 7, 263; Anderson, *A.* 77, 341; *Ed. Phil. Trans.* 20, 57; *cf.* Couerbe, *A. Ch.* [2] 59, 158; Regnault, *A. Ch.* [2] 68, 136; Gerhardt, *Rev. Scient.* 10, 203; Winckler, *Rép. Pharm.* 44, 459; Merck, *A.* 11, 279; Plugge, *Ar. Ph.* [3] 25, 343).

Properties.—Trimetric crystals (containing aq). From CS_2 it separates in anhydrous trimetric crystals $a:b:c$ = ·980:1:·509 (Arzruni, *Z. K.* 1, 302). Lævorotatory; $[\alpha]_j$ (in alcohol) = −136°; (in $CHCl_3$) = −112° (Hesse, *A.* 176, 191; *cf.* Grimbert, *J. Ph.* [5] 16, 295). The rotatory power is much affected by the presence and amount of acid in solution (Hesse; Tykocimer, *R. T. C.* 1, 144). It is a strong base, reddens litmus, and pps. salts of Pb, Fe, Cu, &c. Sol. ether. Codeïne is insoluble in aqueous KOH and hardly more soluble in aqueous NH_3 than in pure water. Its physiological action resembles that of morphine.

Colour reactions.—1. H_2SO_4 forms a greenish solution which, after a week, becomes indigo blue.—2. Fe_2Cl_6 gives no colour.—3. H_2SO_4 and Fe_2Cl_6 gives an intense blue (Lindo, *C. N.* 37, 158).—4. Chloride of iodine gives a yellowish pp. in solutions of salts of codeïne.—5. K_2CrO_4 gives the chromate.—6. K_4FeCy_6 gives no pp. (Plugge, *Ar. Ph.* [3] 25, 793).

Reactions.—1. Hot H_2SO_4 decomposes it, and after diluting, Na_2CO_3 pps. 'amorphous codeïne' as a grey powder [100°], v. sol. alcohol, but ppd. therefrom by ether.—2. Heating with KOH gives off trimethylamine.—3. Heating with a large excess of conc. HClAq forms 'chlorocodide' $C_{18}H_{20}ClNO_2$, apomorphine, and MeCl.—4. HBr gives 'bromocodide' $C_{18}H_{20}BrNO_2$, 'deoxy-codeïne' $C_{18}H_{21}NO_2$ (sol. ether), and 'bromo-tetracodeïne' $C_{72}H_{83}BrN_4O_{12}$ (insol. ether) (Matthiessen a. Wright, *Pr.* 17, 460; 18, 83; Wright, *Pr.* 19, 371, 504).—5. HI and P at 100° to 130° forms some amorphous substances (Wright, *Pr.* 20, 8).—6. Codeïne (1 pt.) evaporated with HPO_3 (3 pts.) and water (5 pts.) is partly converted into dicodeïne $C_{36}H_{42}N_2O_6$ and tetracodeïne $C_{72}H_{84}N_4O_{12}$ (Matthiessen a. Wright, *Pr.* 18, 87).—7. Alkaline $KMnO_4$ expels half the nitrogen as NH_3 (Wanklyn a. Gamgee, *C. J.* 21, 25).—8. PCl_5 forms two bases $C_{18}H_{20}ClNO_2$ and $C_{18}H_{19}Cl_2NO_2$ (v. Gerichten, *A.* 210, 107).—9. *Cyanogen*, passed into a conc. alcoholic solution of codeïne, forms crystals of $C_{18}H_{21}NO_3Cy_2$.

Salts.—B'HCl 2aq; radiate groups of prisms. S. 5 at 15·5° $[\alpha]_j = -108°$.—$B'_2H_2PtCl_6$ 4aq: light yellow powder, gradually becoming crystalline.—B'HI aq: long thin needles. S. 1·3.—$B'HI_3$: red crystals with violet reflex.—$B'HI_5$.—$B'HNO_3$: small prisms, v. sol. hot water.—$B'_2H_2C_2O_4$ 3aq: prisms or scales. S. 3·3 at 15·5°; 200 at 100°.—$B'H_3PO_4$ 1½aq: scales or prisms.—$B'_2H_2SO_4$ 5aq: trimetric prisms. S. 3·3 in the cold $[\alpha]_j = -101°$ at 20°.—$B'H_2S_2O_3$ 5aq: prisms S. 5·5.—B'HSCy ½aq. [100°]. Radiating needles. Chloro-acetate $B'C_2ClH_3O_2$ [154°].—Di-chloro-acetate $B'C_2Cl_2H_2O_2$ [156°].—Tri-chloro-acetate $B'C_2Cl_3HO_2$. [93°].—Chloro-crotonate $B'C_4H_5ClO_2$. [171°].—Tri-chloro-butyrate $B'C_4H_5Cl_3O_2$ [173°].—Di-bromo-pyruvate $B'C_3H_2Br_2O_3$ [70° (Daccomo, *J.* 1884, 1385).

Acetyl derivative $C_{18}H_{20}AcNO_3$. [135°] From codeïne and Ac_2O (Wright, *C. J.* 27, 1031 Hesse, *A.* 222, 212).—B'HCl 2aq.—$B'_2H_2PtCl_6$.

Propionyl derivative $C_{18}H_{20}(C_3H_5O)NO_3$. From codeïne and propionic anhydride. V. sol. alcohol, ether, and benzene. Conc. H_2SO_4 gives a blue colour Forms well-crystallised salts.—B'HCl 2aq.—$B'_2H_2PtCl_6$.—B'HI aq.—$B'H_2C_2O_4$ 3aq (Hesse, *A* 222, 212).

Butyryl derivative $C_{18}H_{20}(C_4H_7O)NO$

Amorphous (Beckett a. Wright, *C. J.* 28, 15).—B'HCl 3aq.—$B'_2H_2PtCl_6$.

Benzoyl derivative $C_{18}H_{20}(C_7H_5O)NO_3$. Crystallises from ether.—B'HCl aq.—$B'_2H_2PtCl_6$.

Succinoxyl derivative $C_{18}H_{20}NO_3(CO.CH_2.CH_2.CO_2H)$ 5aq. Formed by heating codeïne (1 pt.) with succinic acid (2 pts.) at 180° (Beckett a. Wright, *C. J.* 28, 689). Insol. water, ether, and benzene.—B'HCl aq.—$B'_2H_2PtCl_6$.

Camphoryl derivative $C_{18}H_{20}NO_3(C_{10}H_{15}O_3)$. From codeïne and camphoric acid at 180°. Crystalline.—B'HCl 3aq.—$B'_2H_2PtCl_6$.

Methylo-iodide $C_{18}H_{21}NO_3MeI$. Prepared from codeïne and methyl iodide, or from morphine, methyl iodide and sodium in presence of alcohol. Fine needles when hydrated: hard voluminous crystals when anhydrous. With moist silver oxide yields a hydroxyl derivative converted by dehydration into methyl codeine (*q. v.*) (Grimaux, *A. Ch.* [5] 27, 276; *C. R.* 93, 591). By successive treatment with Ac_2O and AgOAc it is converted into $C_{17}H_{14}O_3$ [131°] which crystallises from alcohol in needles (Fischer, *B.* 19, 794).

Ethylo-iodide $C_{18}H_{21}NO_3EtI$. Formed by heating codeïne with EtI and alcohol at 100° (How, *C. J.* 6, 125). Crystalline mass, v. sol. water. Not decomposed by KOH but converted by Ag_2O into a very alkaline hydroxide. The hydroxide changes, when its alkaline solution is evaporated, into ethyl-codeïne. Acetyl derivative $C_{18}H_{20}AcNO_3EtI\frac{1}{2}$aq: crystals, v. sl. sol. cold alcohol (Beckett a. Wright, *C. J.* 28, 318). Gives rise to $C_{18}H_{20}AcNO_3EtCl$ and $(C_{18}H_{20}AcNO_3EtCl)_2PtCl_4$. Butyryl derivative $C_{18}H_{20}(C_4H_7O)NO_3EtI\frac{1}{2}$aq.

Chloride $C_{18}H_{20}ClNO_2$. *Codeyl chloride.* [147°]. Formed by treating codeïne with PCl_5 mixed with $POCl_3$. Colourless leaflets; insol. water, sol. alcohol and ether (v. Gerichten, *A.* 210, 105).—$B'_2H_2PtCl_6$.

Chloro-codide $C_{18}H_{20}ClNO_2$. Formed by prolonged heating of codeïne (1 pt.) with conc. HCl (12 pts.) at 100° (Matthiessen a. Wright, *Pr.* 17, 460; 18, 83; *A. Suppl.* 7, 364). Amorphous; v. sol. alcohol and ether. Water at 140° gives HCl and codeïne. Conc. HCl at 140° gives MeCl and apomorphine.—B'HCl: amorphous.—$B'_2H_2PtCl_6$.

Bromo-codide $C_{18}H_{20}BrNO_2$. From codeïne and HBrAq (S.G. 1·5) at 100° (Wright, *Pr.* 19, 371). Unstable.—B'HBr: gummy.

Chloro-codeïne $C_{18}H_{20}ClNO$, $1\frac{1}{2}$aq. [170°]. From codeïne, $KClO_3$, and HCl. Crystalline powder: sl. sol. ether and hot water, v. e. sol. NH_3Aq.—$B'_2H_2SO_4$ 4aq: prisms.—$B'_2H_2PtCl_6$.

Chloride $C_{18}H_{19}Cl_2NO_2$. *Chloro-codeyl chloride.* [196°]. Formed by heating codeïne (1 mol.) with PCl_5 ($2\frac{1}{2}$ mols.) and $POCl_3$ at 70° (v. Gerichten, *A.* 210, 105). Trimetric prisms; insol. water, v. sol. alcohol, ether, and benzene. Its hydrochloride crystallises in grouped needles.—$B'_2H_2PtCl_6$.

Bromo-codeïne $C_{18}H_{20}BrNO_3$. [162°]. From codeïne and bromine-water. Needles (containing $\frac{1}{2}$ aq or $1\frac{1}{2}$ aq). V. sl. sol. water, v. e. sol. NH_3Aq.—$B'_2H_2PtCl_6$.—B'HBr aq: prisms.

Ethylo-hydrate B'EtOH. Decomposes on evaporation of its aqueous solution forming bromo-ethyl-codeïne (*B.* 15, 1485).

Chloride $C_{18}H_{19}BrClNO_2$. [131°]. From bromo-codeïne and PCl_5. Prisms; sol. alcohol and ether.

Tri-bromo-codeïne $C_{18}H_{18}Br_3NO_2$. From bromo-codeïne and bromine-water (Anderson). Amorphous powder.—$B'_2$3HBr.—$B'_2H_2PtCl_6$.

Di-iodo-codeïne $C_{18}H_{19}I_2NO_3$ (?). From codeïne hydrochloride and ICl. Crystals (from alcohol). Insol. water.—$B'_2H_2PtCl_6$ aq.

Nitro-codeïne $C_{18}H_{20}(NO_2)NO_3$. From codeïne and hot dilute HNO_3 (S.G. 1·06). Silky laminæ (from alcohol). Sl. sol. boiling water (Anderson).—$B'_2H_2PtCl_6$ 4aq.—$B'_2H_2SO_4$ 2aq (at 100°): radiating needles.

Dicodeïne $(C_{18}H_{21}NO_3)_2$ 2aq. Formed by heating codeïne with dilute H_2SO_4, with P_2O_5, or with oxalic acid (Anderson, *Ed. Phil. Trans.* 20 [1] 57; Armstrong, *C. J.* 24, 56; Wright, *C. J.* 25, 506; 28, 312, 696). Amorphous powder. Insol. water, sol. alcohol and ether. Immediately ppd. from its salts by Na_2CO_3 (codeïne comes down only after some time). Fe_2Cl_6 gives no colour. HNO_3 gives a pale orange tint. Hot conc. HCl converts it into $C_{72}H_{83}ClN_4O_{11}H_4Cl_4$. HI and phosphorus at 120° form $C_{136}H_{133}IN_8O_{20}H_8I_8$ (?).

Salt.—$B''H_2Cl_2$ 6aq.

Acetyl derivative $(C_{18}H_{20}AcNO_3)_2$. From dicodeïne and Ac_2O (Beckett a. Wright, *C. J.* 28, 15). Amorphous; v. sol. ether.—$B''H_2Cl_2$ 5aq: crystalline.—$B''H_2PtCl_6$.

Tricodeïne $(C_{18}H_{21}NO_3)_3$. A product of the action of H_2SO_4 or of $ZnCl_2$ on codeïne (Wright, *C. J.* 25, 507; 27, 101; *Pr.* 20, 203). Amorphous. Sol. alcohol and ether. Its hydrochloride is amorphous and extremely deliquescent. Conc. HCl converts it on heating into apocodeïne. Fe_2Cl_6 gives no colour at first, but afterwards a reddish-purple. HNO_3 gives a blood-red colour. Na_2CO_3 immediately pps. it from solutions of its salts (difference from codeïne). Hot concentrated hydrochloric acid forms $C_{108}H_{114}N_6O_{12}H_6Cl_6$.

Tetracodeïne $(C_{18}H_{21}NO_3)_4$. From codeïne and P_2O_5. Formed also by boiling codeïne with benzene and NaOEt (Wright, *C. J.* 27, 107; 28, 324). Amorphous; sol. alcohol; insol. ether. Its hydrochloride is amorphous and deliquescent. Fe_2Cl_6 gives immediately a reddish-purple colour. HNO_3 gives a blood-red colour. $K_2Cr_2O_7$ and H_2SO_4 gives an evanescent red colour (this reaction is given also by tricodeïne, but no colour is got with codeïne or dicodeïne). Na_2CO_3 immediately pps. tetracodeïne from its salts. Boiling aqueous HCl has no action. Boiling HI and phosphorus form $C_{136}H_{150}I_2N_8O_{22}H_8I_8$ (?).

Acetyl derivative $(C_{18}H_{20}AcNO_3)_4$. From tetracodeïne and Ac_2O at 120°. Amorphous.—$B''_2H_2PtCl_6$.

Bromo-tetracodeïne $C_{72}H_{83}BrN_4O_{12}$. From codeïne and HBr. HCl forms $C_{72}H_{83}ClN_4O_{12}H_4Cl_4$. Hydric bromide forms bromo-tetramorphine $C_{68}H_{75}BrN_4O_{12}$.

Salt.—$C_{72}H_{83}BrN_4O_{12}H_4Br_4$.

Deoxycodeïne $C_{18}H_{21}NO_2$. From codeïne and HBr. Insol. water, sol. alcohol and ether. Turns brown in air.—B'HBr: small crystals.

Apocodeïne $C_{18}H_{19}NO_2$. Formed by heating codeïne hydrochloride with a conc. solution of $ZnCl_2$ for 15 minutes (Matthiessen a. Burnside, *Pr.* 19, 71). Gummy mass; insol. water, sol. alcohol and ether. Gives a blood-red colour with HNO_3.—B′HCl: amorphous. Acts as a mild emetic.

Methyl-codeïne $C_{19}H_{23}NO_3$. *Di-methyl-morphine.* [119°]. Prepared by evaporating the product of the action of silver oxide, or of KOH, on codeïne methylo-iodide. The substance separates out as an oil, which solidifies on desiccation. Hard, brilliant laminæ. It appears to possess all the properties of a tertiary base and to be formed by the dehydration of methyl codeïne hydroxide. With sulphuric acid it gives a brown colouration, turning violet on addition of water (Grimaux, *A. Ch.* [5] 27, 283).

Ethyl-codeïne $C_{18}H_{20}EtNO_3$. Formed by evaporation of a solution of codeïne ethylo-hydroxide.

Methylo-iodide $C_{18}H_{20}EtNO_3MeI$. Readily formed by the union of MeI with ethyl-codeïne.

Methylo-hydroxide B′MeOH. Formed by the action of moist Ag_2O on the methylo-iodide. On heating to 130° it decomposes into methyl-ethyl-propyl-amine and a body $C_{15}H_{10}O_2$ (Gerichten a. Schrötter, *B.* 15, 1486). The compound $C_{15}H_{10}O_2$ [65°] is converted into phenanthrene by distillation with zinc-dust. According to Grimaux (*C. R.* 93, 591), a crystalline tertiary base (? methyl-ethyl-codeïne) [132°] is formed by heating ethyl-codeïne methylo-iodide with moist Ag_2O or KOH.

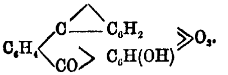
Bromo-ethyl-codeïne $C_{18}H_{19}EtBrNO_3$. Long white needles. Sol. acids and strong NH_3. Tertiary base. Formed by evaporation of a solution of the ethylo-hydrate of bromo-codeïne.

Ethylo-hydrate B′MeOH. Formed by the action of moist Ag_2O on the methylo-iodide. On evaporating the solution to dryness it decomposes into methyl-ethyl-propyl-amine and a body $C_{15}H_9BrO_2$ (Gerichten a. Schrötter, *B.* 15, 1485). This compound $C_{15}H_9BrO_2$ [122°] is converted by CrO_3 into a substance which is apparently a quinone.

DICODETHINE *v. Ethylene*-MORPHINE.

CODETHYLENE *v. Ethyl*-MORPHINE.

CŒRULEIN $C_{20}H_8O_6$ *i.e.*



Formation.—1. By heating galleïn with concentrated sulphuric acid at 190°–200°, an olive-brown solution is formed, from which the cœruleïn is precipitated by water.—2. By oxidation of cœrulin.

Properties.—Dark-blue, metallic glistening crystals, sl. sol. water, alcohol and ether. When heated with *zinc-dust* phenyl-anthracene is produced.

Triacetyl derivative $C_{20}H_7O_3(OAc)_3$, red needles, sol. alcohol, acetone and chloroform, readily decomposed with separation of cœruleïn (Buchka, *A.* 209, 272).

CŒRULIN $C_{20}H_{12}O_7$ *i.e.*

$C_6H_4{<}\begin{matrix}C{-}C_6H_2(OH)_2\\ C(OH){>}C_6H(OH)_2\end{matrix}{>}O$. Formed by the action of concentrated sulphuric acid on gallin; formed also by reduction of cœruleïn with ammonia and zinc-dust (Baeyer, *B.* 4, 556, 663): the solution is acidified and agitated with ether, on evaporation of which cœrulin is left as a red substance, sol. alcohol, ether and acetic acid with golden-green fluorescence. It is readily oxidised to cœruleïn.

Tetra-acetyl derivative $C_{20}H_8O_2(OAc)_4$. [256°]. Cannot be prepared directly from cœrulin, but indirectly from cœruleïn, acetic anhydride and zinc-dust; yellow needles sol. alcohol, chloroform and benzene, converted on oxidation into tri-acetyl-cœruleïn.

Constitution.—Cœrulin bears to gallin (*q. v.*) the same relation that phenol-phthalidin bears to phenol-phthalin, as shown by its analogous method of formation (Buchka, *A.* 209, 274).

CŒRULIGNOL $C_{10}H_{14}O_2$ *i.e.* $C_9H_{10}(OMe)(OH)$. *Blue-oil.* (241° cor.). S.G. ^{15} 1·06. Obtained first by Reichenbach among the higher boiling portions of beech-tar oil, and characterised by giving a blue colouration with baryta water. Is best separated by boiling the oil for some time with acetic acid just strong enough to dissolve it. On pouring the solution into water the compound separates out. Colourless oil, of creasote-like odour, m. sol. hot water, alcohol, ether and acetic acid. From its reaction with nitrobenzene and strong sulphuric acid it appears to be a homologue of pyrocatechin, probably of guaiacol (Pastrovich, *M.* 4, 188). It gives a blue colouration with *baryta water* or *bleaching powder*; with *ferric chloride* in alcoholic solution, a green, but in aqueous solution, a carmine-red colouration. Heated with *hydrochloric* acid it forms a substance $C_9H_{12}O_2$ *i.e.* $C_9H_{10}(OH)_2$ crystallising in prisms [56°]. On melting it evolves methyl chloride.

Acetyl derivative $C_{10}H_{13}AcO_2$ (265°); viscid, colourless oil, once obtained in fan-shaped crystals.

Nitro-derivative $C_{10}H_{13}NO_2O_2$ [124°], obtained together with oxalic acid, the principal product, by the action of nitric acid (S.G. 1·12) on cœrulignol. Light yellow crystals, sol. water and alcohol.

CŒRULIGNONE $C_{16}H_{16}O_6$ *i.e.*

$\begin{matrix}O.C_6H_2(OMe)_2\\ |\quad|\\ O.C_6H_2(OMe)_2\end{matrix}$

Tetramethyl-ether of *tetra-oxy-diphenylene-quinone. Cedriret.* One of the products obtained by Reichenbach from beechwood tar (*J. pr.* 1, 1). The crude acetic acid prepared from wood is treated with $K_2Cr_2O_7$ which oxidises the di-methyl-ether of pyrogallol that is present (Liebermann, *B.* 5, 746; 6, 381; *A.* 169, 231; Hofmann, *B.* 11, 335). It is purified by solution in phenol and ppn. by alcohol or ether. Small dark steel-blue needles. Insol. ordinary solvents; cannot be distilled. Dissolves in conc. H_2SO_4 with blue colour, but is decomposed thereby with elimination of one or two methyl groups. Heated with aqueous KOH it forms a green solution, quickly becoming yellow. *Potash-fusion* gives an intense but fugitive violet colour. Reducing agents convert it into hydrocœrulignone $C_{16}H_{18}O_6$ [190°] which is the tetra-methyl-ether of HEXA-OXY-DIPHENYL (*q. v.*).

Cœrulignone of the ethyl series

$\begin{matrix}C_6H_2(OEt)_2.O\\ |\qquad\quad|\\ C_6H_2(OEt)_2.O\end{matrix}$. Greenish-golden glistening prisms. Prepared by the oxidation of diethyl-pyrogallol with chromic acid in acetic acid.

May be reduced to the hydro-derivative $C_6H_2(OEt)_2(OH).C_6H_2(OEt)_2(OH)$ [176°] which crystallises in long white needles (Hofmann, *B.* 11, 801).

Di-bromo-hydrocœrulignone *v.* Hexa-oxy-diphenyl.

COFFEE *v.* Caffeïne and Caffeol.

COLCHICINE $C_{22}H_{25}NO_6$ *i.e.* $C_{15}H_9(OMe)_3(NHAc)(CO_2Me)$ (?). *Methyl ether of colchiceïn* [145°]. Occurs in all parts of the meadow-saffron (*Colchicum autumnale*), especially in the seeds (Pelletier a. Caventou, *A. Ch.* [2] 14, 69; Geiger a. Hesse, *A.* 7, 274; Hübschmann, *Ar. Ph.* [2] 92, 330; Aschoff, *Ar. Ph.* [2] 89, 4; Bley, *Ar. Ph.* [2] 89, 18; Hübler, *C. C.* 1865, 536; Flückiger, *Ph.* [3] 7, 372; Hertel, *C. C.* 1881, 501; *Ph.* [3] 12, 498; Rosenwasser, *Ph.* [3] 8, 507; Houdès, *C. R.* 98, 1442; Zeisel, *C. R.* 98, 1587; *M.* 4, 162; 7, 557; 9, 1).

Preparation.—The whole seeds are extracted with hot 90 p.c. alcohol, and the residue digested with water. The aqueous solution is shaken with $CHCl_3$. On evaporation the chloroform leaves a syrupy residue, which after some days begins to crystallise. It is recrystallised repeatedly from alcohol and chloroform, and finally from water (Zeisel).

Properties.—Yellowish-white powder. Sol. water and alcohol, insol. ether; darkens when exposed to the light. It is lævorotatory. Mineral acids colour the solution yellow. Weak alkalis also give a yellow colour; concentrated acids yield a yellow resinous pp. Conc. HNO_3 gives a violet colour. Conc. H_2SO_4 with a trace of nitrate gives a yellow green. Br water a yellow pp. Iodine in KI a brown pp. Fe_2Cl_6 no colour except on warming, when a green colour is produced. $HgCl_2$ in neutral solutions gives a slight turbidity, when acid a yellow pp. $AuCl_3$ yellow needles, CdI_2, potassium bismuth iodide, potassium mercuric chloride, phosphotungstic and phosphomolybdic acids, and chromates give yellow pps. Tannic acid in acid and neutral solution a white pp. It forms an addition compound with $CHCl_3$ of the formula $C_{22}H_{25}NO_6.2CHCl_3$ with evolution of heat. Yellow needles decomposed by water. Phenol gives a milkiness, and finally a yellow resin. Colchicine acts as a diuretic, purgative, and irritant poison (Mairet a. Combemale, *C. R.* 104, 439, 515).

Salts.—Colchicine is a weak base, most of its salts being decomposed by water. The aurochloride $B'HAuCl_4$ is stable.

Colchiceïn $C_{21}H_{23}NO_6$ *i.e.* $C_{15}H_9(OMe)_3(NHAc)(CO_2H)$. *Tri-methyl-acetyl-colchicinic acid* [c. 166°].

Preparation.—By warming an aqueous solution of pure colchicine with 2 p.c. H_2SO_4 or 1 p.c. HCl. Separates in white needles. There are also formed methyl alcohol, an acid substance, and a new or possibly two new bases.

Properties.—Shining white needles (containing ½ aq); becomes anhydrous at 140°–150°. Lævorotatory. V. e. sol. alcohol and chloroform, insol. ether and benzene. Sol. mineral acids giving a yellow solution, in the case of HCl with rise of temperature. Alkalis also dissolve it, yielding yellow solutions. Conc. H_2SO_4 and HNO_3 behave with it as with colchicine. Br water, phosphomolybdic acid and aqueous phenol yield slight pps. in the aqueous solution, but not other reagents. In HCl solution it behaves like colchicine with most reagents. From conc. HCl solution $AuCl_3$ ppts. an orange-gold compound, which can be subsequently crystallised in needles. Lead and copper acetates give pps. HCl converts it into the hydrochloride of tri-methyl-colchicinic acid $C_{19}H_{21}NO_5HCl$ which forms a Pt salt $(C_{19}H_{21}NO_5HCl)_2PtCl_4$ 2aq. The dimethyl-colchicinic acid and colchicinic acid are also produced.

Salts.—$B'HAuCl_4$.—$(C_{21}H_{22}NO_6)_2Cu$ 5aq (Zeisel, *M.* 7, 585; 9, 8).

Amide of colchiceïn $C_{21}H_{24}N_2O_5$ *i.e.* $C_{15}H_9(OMe)_3(NHAc)(CONH_2)$ (?). Formed when colchicine and alcoholic NH_3 are heated together in a sealed tube. After evaporating the alcohol a yellow crystalline mass is left, which is recrystallised from alcohol. Two kinds of crystals separate. Those which effloresce contain ½ mol. alcohol.

Properties.—Heated with NaHO it forms colchiceïn and NH_3. It behaves as a base, being sol. HCl, insol. water. Fe_2Cl_6 gives a brown colouration, and in HCl solution KNO_2 gives a violet colour, and the alkaloidal reagents give precipitates. Conc. H_2SO_4 dissolves it, giving a yellow-red colouration (Zeisel, *M.* 9, 26).

COLCHICINIC ACID $C_{16}H_{15}NO_5$ *i.e.* $C_{15}H_9(OH)_3(NH_2)(CO_2H)$ (?).

Preparation.—The hydrochloride remains in the mother-liquor after separating the dimethyl- and trimethyl-derivatives formed from colchiceïn by heating with HCl. After drying at 109° the colchicinic acid is obtained as a yellow powder.

Properties.—HCl solution is ppd. by Br water, KI, $HgCl_2$, $PtCl_4$, $AuCl_3$, CdI_2, and by the usual alkaloidal reagents. Phenol gives no pp. Conc. H_2SO_4 gives a brown colouration; if a nitrate be present, and then excess of NH_3 added, a red colour is produced. Fe_2Cl_6 gives a red-brown colouration (Zeisel, *M.* 9, 22).

Dimethyl-derivative $C_{18}H_{19}NO_5$. [142°]. The hydrochloride is formed with the trimethyl-derivative. It crystallises from hot water as $B'HCl$ aq, from which the free acid is obtained in yellow microscopic prisms by the addition of weak NaHO. These prisms contain 4½aq. A solution gives the usual alkaloid reactions (Zeisel, *M.* 9, 17).

Trimethyl derivative $C_{19}H_{21}NO_5$ *i.e.* $C_{15}H_9(OMe)_3(NH_2)(CO_2H)$? [150°]. From the hydrochloride formed from colchiceïn (*q.v.*). Microscopic prisms (containing 2 aq). It forms a Pt salt $(B'HCl)_2PtCl_4$ 2aq.

COLEÏN $C_{10}H_{10}O_5$ (?) A brittle red resin, which may be extracted by acidulated alcohol from the leaves of *Coleus Verschaffeltii* (Church, *C. J.* 31, 258).

COLLAGEN *v.* Proteïds, *Appendix C.*

COLLIDINE *v.* Tri-methyl-pyridine and Methyl-ethyl-pyridine.

COLLINIC ACID obtained by Fröhde (*J. pr.* 80, 344) by oxidising gelatin with CrO_3 is Benzoic acid.

COLLODION *v.* Cellulose.

COLLOIDS. Name given by Graham to those substances which do not diffuse through porous membranes. *Colloids* are contrasted with *Crystalloids*. *V.* Diffusion, and Physical methods.

COLLOTURINE *v.* Loturine.

COLOCYNTHIN $C_{56}H_{84}O_{23}$ (?) S. (cold) 5; (hot) 5·8. The bitter principle occurring in the pulp of the fruit of *Citrullus Colocynthis* (Vauquelin, *J. Phys.* 84, 338; Braconnot, *J. Ph.* 10, 415; Herberger, *Buchner's Repert.* 35, 368; Bastick, *Ph.* 10, 239; Walz, *Ar. Ph.* [2] 96, 141; 99, 338; Lebourdais, *A. Ch.* [3] 24, 58; Henke, *Ar. Ph.* [3] 21, 200).

Preparation.—The fruit is extracted with alcohol, the alcohol is evaporated, and the residue taken up by cold water; lead acetate is added, and in the filtrate, after removing the excess of lead by H_2SO_4, the colocynthin is ppd. by tannin. The compound with tannin is then decomposed by lead carbonate.

Properties.—Yellowish prisms or powder. Sol. water and alcohol, insol. ether, CS_2, benzene, chloroform, and ligroïn. Conc. H_2SO_4 gives a red colouration. It easily reduces Fehling's solution. Boiling aqueous HCl gives a dark green greasy pp., and the solution still reduces Fehling's solution. According to Walz, colocynthin is split up by boiling dilute H_2SO_4 into glucose (2 mols.) and a resin colocynthein $C_{44}H_{64}O_{13}$.

COLOMBIN *v.* COLUMBIN.

COLOPHENE. This name is applied by Armstrong and Tilden to the viscid yellow oil left after distilling all that is volatile in steam from the crude product of the action of H_2SO_4 on the terpenes. It is probably a mixture of polymerides of these hydrocarbons (*C. J.* 35, 748). Deville (*A. Ch.* [2] 75, 66; [3] 27, 85) applied the name to the portion of the product of the action of H_2SO_4 on French turpentine that boils a little above 300°. This might be called dicamphene, $C_{20}H_{32}$. A similar product occurs among the products of the distillation of colophony, but it differs from Deville's colophene in forming a grease when rubbed with slaked lime. *V. also* TERPENES.

COLOPHONY *v.* TERPENES and TURPENTINE.

COLUMBIC ACID $C_{21}H_{22}O_6$ aq? An acid which may be extracted by lime-water from Columbo root (Bödecker, *A.* 69, 47). Amorphous, nearly insol. water, v. sol. alcohol, sl. sol. cold ether.—$Pb_2A'_4Pb(OH)_2$ aq?.

COLUMBIN $C_{21}H_{22}O_7$. [182°]. S. (alcohol) 3 at 78°. Occurs in the Columbo root (from *Menispermum palmatin*, together with berberin and a substance [220°] which crystallises from HOAc in prisms. Prepared by extracting the root with ether. On evaporation a crystalline residue, together with a fatty substance, separates out; the latter is removed by washing with ether, and the former crystallised from alcohol (Wittstock, *P.* 19, 298; Liebig, *P.* 21, 30; Röse, *P.* 19, 441; Bödecker, *A.* 69, 39; Paterno and Oglialoro, *G.* 9, 66; Alessandri, *Ph.* [3] 12, 995). Tastes very bitter. V. sl. sol. cold water, alcohol, and ether.

COMANIC ACID $C_5H_3O_2.CO_2H$ *i.e.*

$$CH\!\left<\begin{matrix}CO.CH\\CH.O\end{matrix}\right>C.CO_2H\ (?)\quad [250°].$$

Preparation.—1. Comenic acid (*q.v.*) is treated with PCl_5 and the di-chloro-comanic acid produced is reduced by HI (b.p. 127°) (Ost, *J. pr.* [2] 29, 62).—2. Chelidonic acid is heated *in vacuo* at 280° (Haitinger a. Lieben, *M.* 6, 279).

Properties.—Oblique prisms. Sl. sol. water. Gives no colour with Fe_2Cl_6.

Reactions.—1. Decomposed by excess of *baryta* with precipitation of the salt of an acid which gives a brown colour with Fe_2Cl_6. On warming the pp. with excess of baryta it changes to baric oxalate, acetone being evolved (compare chelidonic acid).—2. Heated by itself it splits up into CO_2 and $C_5H_4O_2$, pyrocomane, a neutral substance, insol. water, [32°] (c. 213°).—3. Warmed with conc. NH_3 it reacts thus (compare the behaviour of comenic and of oxycomenic acids): $C_6H_4O_4 + NH_3 = C_6H_5NO_3 + H_2O$. The product is oxy-pyridine carboxylic (β-oxy-picolinic) acid $C_5H_3N(OH)(CO_2H)$.—4. When comanic acid (10 g.), *hydroxylamine hydrochloride* (6 g.), Na_2CO_3 (4·5 g.) and water (100 g.) are warmed together, the sparingly soluble oximido- acid separates $C_5H_3O(NOH).CO_2H$. Crystallised from water, it forms crystals which decompose at 200°. With fuming HCl at 200° this forms $C_5H_5NO_2$, a crystalline body that is very soluble in water. The oximido- acid is reduced by Zn and HCl to oxy-pyridine carboxylic acid. From this it would appear that the oximido- acid is di-oxy-pyridine carboxylic (di-oxy-picolinic) acid (H. Ost, *J. pr.* [2] 29, 378).—5. *Ethylamine* converts comanic acid into oxy-ethyl-pyridine-carboxylic (oxy-ethyl-picolinic) acid, $C_5H_2N(OH)(CO_2H)Et$. This acid splits up at 160° into CO_2 and (?) oxy-ethyl-pyridine.

Salts.—BaA'_2 aq: v. sol. water.—BaA'_2 3aq. AgA'.

Ethyl ether EtA'. [103°]. Prisms; not acted upon by AcCl.

Chloro-comanic acid $C_6H_3ClO_4$. [247°]. Formed, together with the following, from comenic acid by successive treatment with PCl_5 and water. Needles.

Di-chloro-comanic acid $C_6H_2Cl_2O_4$. [217°]. Needles (from alcohol). HI converts it into comanic acid.

COMBINATION, CHEMICAL, LAWS OF.—Chemistry concerns itself with the changes of composition and properties which certain definite kinds of matter undergo. Those kinds of matter which are studied in chemistry are divided into two classes, elements and compounds. Elements are those kinds of matter which undergo chemical change only by combining with other elements or compounds. Compounds may combine with other compounds or with elements, or they may be separated into two or more elements or compounds each unlike the others, and each weighing less than the original quantity of the compound used.

The expression 'homogeneous bodies' has sometimes been employed to denote elements and compounds, and to distinguish these from mixtures which palpably consist of unlike portions.

The law of the conservation of matter holds good in all chemical, as in all physical, changes. This law may be stated as follows as regards chemical occurrences:—*When homogeneous bodies interact to produce new bodies, the sum of the masses of the bodies produced is equal to the sum of the masses of those which have interacted to produce them.*

The proof of this law is found in the whole body of chemical and physical science. A few numbers are here given, taken from the researches of Stas, which were conducted with very great care and accuracy.

(1) Silver iodide is the sole product of the combination of iodine and silver; if the law of the conservation of mass holds good, the mass of silver iodide formed should be exactly equal to the sum of the masses of silver and iodine used.

Iodine used.	Silver used	Sum of Silver and Iodine.	Silver iodide formed.	Differences.
32·4665	27·6223	60·0888	60·086	−·0028
46·8282	39·8405	86·6687	86·6653	−·0034
44·7599	38·0795	82·8394	82·8375	−·0019
160·2752	136·3548	296·6300	296·624	−·0060
96·7964	82·3631	179·1595	179·159	−·0005

The mass of silver iodide formed was in every case slightly less than the sum of the masses of silver and iodine used; but this is accounted for by the fact that it is impossible to collect absolutely the whole of the silver iodide formed. The differences amount to about $\frac{1}{20,000}$ of the total weight, and fall within the limits of necessary experimental errors.

(2) In another series of experiments Stas heated silver iodate, and so decomposed it into silver iodide and oxygen; the differences between the mass of iodate used and the sum of the masses of iodide and oxygen obtained amounted to about $\frac{1}{78,000}$ of the total weight. Here are a few of the results:—

Silver iodate	Silver iodide	Oxygen	Sum	Difference
98·2681	81·5880	16·6815	98·2695	+·0014
156·7859	130·1755	26·6085	156·7840	−·0019.

Homogeneous bodies interact to produce new homogeneous bodies in certain definite and fixed ratios; there is a constant ratio between the masses of the interacting bodies, and also between the mass of each interacting body and the mass of the product, or of each of the products, of the change.

The validity of this statement is assumed in all chemical investigations. Stas carried out a series of elaborate researches in order to determine whether the statement is or is not absolutely accurate. The following numbers taken from Stas' memoirs are illustrations of his results.

(1) Potassium chloride was caused to react with nitric acid to form potassium nitrate; the masses of potassium chloride and of potassium nitrate were determined.

Potassium chloride taken	Potassium nitrate formed	Potassium nitrate from 100 parts of chloride	Difference from mean
50·7165	68·6938	135·643	−·002
80·2610	108·8665	135·638	−·007
72·1022	99·8050	135·647	+·002
50·2175	68·1200	135·649	+·004
48·9274	68·3675	135·645	·000
69·8836	94·7900	135·640	−·005
14·2578	19·3415	135·655	+·010
		Mean 135·645	

The divergences from the mean are very small and are wholly accounted for by necessary experimental errors.

(2) A solution of silver was added to a solution of potassium bromide until the whole of the bromine was precipitated as silver bromide, and from the results was calculated the mass of potassium bromide which reacted with 100 parts by weight of silver. The numbers obtained established the absolute identity of the ratio of silver to potassium bromide in every experiment. Thus five experiments gave the following results:—

Potassium bromide	Silver	Potassium bromide reacting with 100 parts of silver	Difference from mean
9·20526	8·34305	110·332	−·008
20·12315	18·23665	110·343	+·003
15·8310	14·3451	110·357	+·017
11·0613	10·0253	110·334	−·006
16·3032	14·77495	110·335	−·005
		Mean 110·340	

The relations between the masses of interacting homogeneous bodies are expressed in the three laws of chemical combination, usually known as the law of fixity of composition, or the law of constant proportions; the law of multiple proportions; and the law of reciprocal proportions, or the law of combining weights. These laws may be stated in various forms of words; the following are fairly satisfactory.

Law of constant proportions. *The masses of the constituent elements of every compound stand in an unalterable ratio to each other, and also to the mass of the compound formed.*

Law of multiple proportions. *When two elements combine to form more than one compound, the masses of one of the elements which combine with a constant mass of the other element bear a simple relation to each other.*

Law of reciprocal proportions; or law of combining weights. *The masses of different elements which severally combine with one and the same mass of another element are also the masses of these different elements which combine with each other, or they bear a simple relation to these masses.*

When gaseous homogeneous bodies react to produce new gaseous bodies, the relations between the volumes of the interacting bodies and the volume of the product, or the volumes of the products, are expressed in the law of volumes or the law of Gay-Lussac.

Law of volumes. *When gaseous elements or compounds interact, the volumes of the interacting bodies bear a simple relation to each other, and also to the volumes of the gaseous products of the reaction.*

The law of constant proportions asserts the absolute invariability of the composition of every chemical compound. This law was finally gained as one result of the long controversy waged between Berthollet and Proust throughout the years 1801 to 1808. Many of the older chemists regarded every chemical compound as of fixed composition; the investigations of Bergmann and Lavoisier, for instance, implicitly assumed the validity of this law of fixity of composition. Indeed, even so far back as the middle of the 17th century Van Helmont spoke of the saturation-point which is reached when a definite quantity of an acid is added to a specified quantity of a base. The experiments of Richter in the last years of the 18th century rendered it probable that the masses of two acids, which severally neutralise one and the same mass of a given base, bear a constant ratio to each other independently of the nature of the base with which they react.

Berthollet, in his *Essai de statique chimique*, published in 1803, stated the fundamental law of chemical action, to the effect that the amount of a chemical change is dependent on the affinities and the masses of the reacting bodies. One of the conclusions which he drew from this generalisation was, that the composition of the products of a chemical reaction may vary within certain limits, which are determined by the relative masses of the interacting bodies, and by the physical states of these bodies, and of those produced in the change. Proust opposed this notion of variability of composition. He analysed with great care many series of compounds, chiefly metallic oxides and sulphides, and as a final result he established the law of fixity of composition, or of constant proportion, on a firm basis of experimentally determined facts.

Proust admitted that two elements might combine in more than one ratio. Indeed he analysed various pairs of oxides and sulphides of the same metal; for instance, he gave the following analyses of oxides of copper and of tin:—

Copper oxides	(1)	(2)	*Tin oxides*	(1)	(2)
Copper =	86·2	80	Tin =	87	78·4
Oxygen =	13·8	20	Oxygen =	13	21·6

Proust contented himself with stating the results of his analyses of compounds in percentages of the constituent elements. Had he calculated the masses of oxygen which were combined with the same mass of copper, or the same mass of tin, he might perhaps have forestalled Dalton and announced the law of multiple proportions. For Proust's analyses quoted above, if thus treated, give these results:—

Copper oxides	(1)	(2)	*Tin oxides*	(1)	(2)
Copper =	86·2	86·2	Tin =	87	87
Oxygen =	13·8	21·5	Oxygen =	13	24

Dalton analysed two compounds of carbon and hydrogen, and found that the ratio of carbon to hydrogen in one compound was twice that of carbon to hydrogen in the other; in other words, he found that a fixed mass of hydrogen combined with a definite mass of carbon to form one compound, and with twice that mass of carbon to form another compound. Dalton did not conduct the experiments which led to this result, solely with the view of finding the quantitative laws of chemical combination, but rather with the object of rendering clear the atomic conception of chemical change which at this time was occupying his attention. While determining the composition of series of compounds, he had always in his mind the conception of chemical combination as consisting in the union of extremely minute portions of the combining bodies. These minute portions, or atoms, of an element, he pictured to himself as chemically indivisible, and as all of the same mass; hence, he argued, if two elements combine to form more than one compound, the masses of one of these elements which combine with a fixed mass of the other element must bear a very simple relation to each other, one must be a whole multiple of the other, because portions of atoms cannot combine, and all the atoms of the same element have the same mass.

The law of multiple proportions was a necessary consequence of the Daltonian atomic theory. As a matter of fact, the law was deduced from experimental data by reasoning directed by the mechanical conceptions of this theory (*v.* ATOMIC AND MOLECULAR WEIGHTS, vol. i. pp. 336–7). Dalton's analyses were not very accurate. There can be little doubt that it was not the analytical results which led him to the discovery of the law of multiple proportions, but that the law was tentatively deduced from the atomic conception he had formed of chemical processes, and was then confirmed by the results of his analyses of compounds.

The announcement of the law of multiple proportions at once threw a flood of light on the empirical data already amassed regarding chemical composition; and it also led to more careful analyses of numerous compounds, by showing the importance of these analyses, and by interpreting their results in terms capable of general application.

After the publication of Dalton's *New System of Chemical Philosophy* in 1808, chemists everywhere busied themselves with making accurate analyses of compounds. Some chemists accepted the atomic theory of Dalton, others preferred to speak of combining proportions, or equivalents, rather than of atoms, of elements; but whether accepting or rejecting his theory, all were influenced by Dalton's teaching. The development of the atomic theory and the verification of the laws of chemical combination are indissolubly bound together.

If the atomic theory were granted, not only the law of multiple proportions, but also that of reciprocal proportions, followed as a necessary consequence. For the masses of two or more elements which combine with each other must be the masses, or whole multiples, or sub-multiples, of the masses, of those elements which severally combine with a fixed mass of some other specified element; because combination occurs between atoms, and atoms are chemically indivisible, and all the atoms of any element are of the same mass.

The outcome of the researches of Berzelius and his followers into the composition of compounds was to establish the laws of chemical combination on a firm basis; but so intimately were those investigations connected with the development of the atomic theory, and with the controversies which attended that development, that many chemists who demurred to the theory were inclined to deny the absolute validity of the laws as expressions of fact, and to think that these laws must stand or fall with the theory which had first given them importance.

The results of the laborious researches of Stas[1] have shown that the laws of chemical combination by mass are perfectly accurate statements of facts which hold good in all chemical processes.

Some of the results obtained by Stas have been already given (p. 236). The following analyses of silver chloride, and of ammonium chloride, prepared by different methods, serve to show that the composition of each of these two compounds at any rate is absolutely fixed:—

Method of preparation of silver chloride	Grams of silver chloride obtained from 100 of silver
1. Ag burnt in Cl gas . .	132·842
2. Ag dissolved in HNO_3Aq, and ppd. by HCl gas .	132·847
3. Ag dissolved in HNO_3Aq, and ppd. by HClAq .	132·848
4. Ag dissolved in HNO_3Aq, and ppd. by NH_4ClAq .	132·842

The ammonium chloride analysed was prepared in four different ways:—

(1) Commercial salammoniac was dissolved in water and boiled with nitric acid to destroy organic matter; the liquid was decomposed by pure lime; the ammonia produced was led into water and then neutralised by hydrochloric acid; the ammonium chloride was sublimed in a stream of ammonia.

(2) Commercial sulphate of ammonia was heated with sulphuric acid, then boiled with nitric acid; the solution was treated in the same way as described in (1).

(3) A solution of potassium nitrite was mixed with potash, zinc-dust was added, and the liquid warmed; the nitrite was thus reduced to ammonia, which was led into water, and then neutralised by hydrochloric acid, the ammonium chloride was sublimed in an ammonia-stream.

(4) A part of the ammonium chloride prepared in (3) was sublimed *in vacuo*.

Weighed quantities of the different preparations were dissolved in water, and the quantity of silver required for the precipitation of all the chlorine was very accurately determined; experiments were conducted at different temperatures. A selection is given from the results:—

		Grams used	Silver used	Grams NH_4Cl decomposed by 100 grams silver
Specimen (1)	at 20°	11·79643	23·7843	49·598
	at 100°	89·62130	79·88613	49·5974
„ (2)	at 20°	11·80844	23·8086	49·597
	at 100°	13·40631	27·0277	49·602
„ (3)	at 20°	6·25216	12·60716	49·593
	at 20°	10·71756	21·6093	49·597
„ (4)	at 20°	13·5129	27·2429	49·598
	at 20°	6·2250	12·5523	49·592
			Mean	49·5968

One of the forms in which the law of reciprocal proportions may be stated is as follows: *The elements combine in the ratios of their combining weights, or in ratios which bear a simple relation to these.* By the combining weight of an element is here understood the smallest mass of that element which combines with unit mass of a standard element (*v.* COMBINING WEIGHTS OF ELEMENTS). Suppose the standard element were oxygen; then if the combining weight of an element were determined from analyses of different compounds of that element, all of which compounds contained oxygen, the law asserts either that the same value for the combining weight should be deduced from all the analyses, or that the different values found should bear a simple relation to each other. Stas proved the absolute accuracy of the law as regards silver, by determining the mass of this element combined with 16 parts by weight of oxygen in various compounds. The compounds chosen were, silver iodate, bromate, chlorate, and sulphate. Stas reduced these compounds to silver iodide, bromide, chloride, and sulphide, respectively, and then determined the amount of silver in these salts.

The following values were obtained for the mass of silver combined with iodine, &c., and 16 parts by weight of oxygen: (1) From analyses of iodide prepared by reducing iodate 107·928; (2) from analyses of bromide prepared by reducing bromate 107·921; (3) from analyses of chlorate prepared by reducing chloride 107·937; (4) from analyses of sulphide prepared by reducing sulphate 107·920. Stas further reduced potassium chlorate to chloride and then determined the mass of silver needed to precipitate the chlorine which was combined with 16 parts of oxygen in the original chlorate; he thus indirectly obtained a value for the combining weight of silver, meaning thereby the mass of this element which combines with that mass of chlorine which enters into union with 16 parts by weight of oxygen; the number found was 107·930. Another method which Stas used for testing the accuracy of the law of reciprocal proportions consisted in finding the ratio of the masses in which two elements united to form a binary compound, and also the ratio of the masses in which the same pair of elements were united in a compound formed by the addition of a third element to the first binary compound. Stas determined the ratio of silver to iodine in silver iodide and iodate, of silver to chlorine in silver chloride and chlorate, and of silver to bromine in silver bromide and bromate. The results proved the absolute accuracy of the law.

There can be no doubt as to the accuracy of the laws of chemical combination by weight. These laws are perfectly accurate statements of facts, and they hold good in every chemical change.

The law of combination of gaseous elements and compounds by volume, enunciated by Gay-Lussac, has not yet been subjected to so rigorous an examination as that which the laws of combination by weight have undergone.

The ratio of the volumes in which hydrogen and oxygen combine to form water was determined by Lavoisier, in 1783, to be 1·91:1. Other chemists stated the ratio to be approximately

---

[1] *Recherches sur les rapports réciproques des poids atomiques* [1860]. *Nouvelles recherches sur les lois des proportions chimiques, sur les poids atomiques et leurs rapports mutuels* [1865]. A German translation of both memoirs was published in 1867, with the title *Untersuchungen über die Gesetze der chemischen Proportionen, über die Atomgewichten und ihre gegenseitigen Verhältnisse.*

2:1. In 1805 Gay-Lussac and Humboldt announced that the ratio was exactly 2:1, and in 1808 Gay-Lussac made the generalisation, which he based on numerous experiments, that the volumes of gaseous elements or compounds which combine to form gaseous products can be expressed by small whole numbers, and that the volume of the gaseous product of such combinations is either the sum of the volumes of the constituents or it bears a very simple relation ($\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c.) to this sum. Gay-Lussac's experiments showed, for instance, that 1 volume of nitrogen combines with 3 volumes of hydrogen to form 2 volumes of ammonia, and with 2 volumes of oxygen to form 2 volumes of nitrogen dioxide, &c.

Investigations have recently been made by Scott regarding the volumetric ratio in which hydrogen and oxygen combine to form water. The results (*v.* Scott, *Pr.* 1887. 398; *B.A.* 1887. 668; *N.* 37, 439) do not finally settle the ratio but they all tend to show that it is slightly less than 2:1, the most probable value being 1·997:1.

The laws of chemical combination are all included in the two statements:

1. The elements combine in the ratios of their combining weights, or in ratios which bear a simple relation to these.
2. The gaseous elements combine in the ratios of their combining volumes, or in ratios which bear a simple relation to these.

By *combining weight* is here meant the smallest mass of an element which combines with unit mass of some specified element taken as a standard; and by *combining volume* is meant the smallest volume of a gaseous element which combines with unit volume of some specified gaseous element taken as a standard.

The first statement has been amply verified by accurate experiments; the second does not yet stand on so firm an experimental basis.

In connexion with this article *v.* the articles ATOMIC AND MOLECULAR WEIGHTS; COMBINING WEIGHTS OF ELEMENTS; COMPOSITION, CHEMICAL; EQUIVALENTS; FORMULÆ. M. M. P. M.

COMBINING WEIGHTS OF THE ELEMENTS.- The laws of chemical combination by mass are expressed in the statement, *the elements combine in the ratios of their combining weights, or in ratios which bear a simple relation to these.* The term *combining weight* is here taken to mean the smallest mass of an element which combines with unit mass of a standard element. Hydrogen is adopted as the standard element; hence the practical definition of combining weight, as here understood, is the smallest mass of an element that combines with 1 part by weight of hydrogen. But many elements do not combine with hydrogen; it is therefore often necessary to make use of some element other than hydrogen as a standard.

All the elements except fluorine and bromine form oxides, and most of the elements combine with chlorine. These two elements, oxygen and chlorine, are therefore frequently used as standards of reference in determinations of combining weights.

Oxygen combines with hydrogen in two ratios (by weight), 8:1 and 16:1; but chlorine and hydrogen combine only in the ratio 35·5:1 (these values are given in round numbers). In accordance with the definition given above, the combining weight of oxygen is said to be 8, and the combining weight of chlorine to be 35·5. The combining weight of an element may then be taken to be the smallest mass of it which combines with 1 part by weight of hydrogen, or 8 parts by weight of oxygen, or 35·5 parts by weight of chlorine.

The same value is found for the combining weights of some elements which form both oxides and chlorides, whether the value is determined from analyses of the compounds with oxygen or with chlorine. Sodium and silicon are cases in point. But in some cases, one value is found for the combining weight of an element from analyses of its oxide, and another value from analyses of its chloride. Thus $\frac{127}{3}$ is the smallest mass of iodine that combines with 35·5 parts by weight of chlorine, but $\frac{127}{5}$ parts by weight of iodine combine with 8 parts of oxygen, and if the combining weight of iodine is deduced solely from analyses of its hydride, the value found is 127. So also, the smallest mass of nitrogen that combines with 1 part by weight of hydrogen is 4·66, but a compound of nitrogen and oxygen is known which is composed of 2·8 parts of nitrogen in union with 8 parts of oxygen.

Different values, then, are frequently obtained for the combining weight of an element according as the combining weight is determined in reference to hydrogen, chlorine, or oxygen, as the standard element. But the different values always bear a simple relation to each other. The following table presents the values found for the combining weights of a few elements; the ratios of the numbers are stated in the last column. Round numbers are given:—

	Combining weights referred to			Ratio of values
	H=1	O=8	Cl=35·5	
Nitrogen . .	4·6	2·8	4·6	5:3:5
Potassium . .	—	9·75	39	1:4

If, then, we define combining weight solely in terms of hydrogen as unity, we can determine the combining weights only of a minority of the elements; if we admit the employment of oxygen and chlorine as standards of reference, we frequently arrive at different values for the combining weight of the same element. One primary object in determining combining weights is to find a basis for a system which shall represent the composition of compounds in formulæ, by showing the number of combining weights of each element which are combined to form that quantity of a specified compound which is represented by its formula. In order to frame a satisfactory system of notation, some compromise must be come to as to the meaning to be given to the term combining weight. The difficulty may be partly overcome by adopting as the combining weight of an element the least common multiple of the numbers which express the masses of the element that severally combine with 1 part by weight of hydrogen, 8 parts of oxygen, and 35·5 parts of chlorine. For instance, in the case of nitrogen, the L.C.M. of 2·8 and 4·66 is 14; and in the case of arsenic, the L.C.M. of 25 and 15 is 75.

The values thus obtained are usually adopted when it is desired to frame a fairly satisfactory definition for the term combining weight. These values are either the same as the atomic weights of the elements, or the latter are whole multiples of the former numbers. If a satisfactory and consistent system of notation is to be based on the combining weights of the elements, it is better to adopt for the combining weights values which are always identical with the atomic weights. The term combining weight of an element must then be taken to mean either the smallest whole number, or a whole multiple of the smallest whole number, divisible without remainder by each of the numbers that express the masses of the element which combine with 1 part by weight of hydrogen, 8 parts of oxygen, and 35·5 parts of chlorine, respectively. The following table exhibits the smallest masses of each element that combine with 1 part by weight of hydrogen, 8 parts of oxygen, and 35·5 parts of chlorine; it also shows the L.C.M. of these numbers, and the last column contains the whole number by which each L.C.M. must be multiplied in order to get the value used as the combining weight of the specified element in the ordinary chemical notation, which value is identical with the atomic weight of the element. (The values in the table in the next column are given in round numbers.)

The combining weight of an element is sometimes said to be the smallest mass of that element which enters into chemical combination with other elements, the smallest mass of hydrogen which combines chemically being taken as unity. But in order to give an exact meaning to the phrase, 'smallest relative mass of an element which enters into chemical combination with other elements,' it is necessary to add, 'to form a chemically reacting unit of a compound,' or some such expression as this. Now, the only conception of 'the chemically reacting unit of a compound' which has been put into an exact form capable of presentment in quantitative terms and of general application is that which arises from the application of the molecular and atomic theory to chemical occurrences; it is indeed the conception of the molecule. The definition of combining weight as 'the smallest relative mass of an element which enters into chemical combination with other elements' is essentially an atomic and molecular definition, although it is not couched in atomic and molecular language. For many years attempts were made to base a system of representing the composition of compounds on the combining weights of the elements without the help of the conceptions of atom and molecule. That mass of an element which combined with 1 part by weight of hydrogen, or 8 parts of oxygen, was sometimes taken as the combining weight of the element, and sometimes a multiple of this mass was proposed. But it was only when the atomic and molecular theory led the way that a satisfactory and consistent scheme of representing chemical composition was gained. The atomic weight of an element is always equal to, or is a whole multiple of, the least common multiple of the numbers that express the smallest masses of the element which combine with 1 part by weight of hydrogen, 8 parts of oxygen, and 35·5 parts of chlorine, respectively; the principles which guide chemists in their choice of the multiple are set forth in the article ATOMIC AND MOLECULAR WEIGHTS. If accurate values are to be found for the atomic weights of the elements, it is evident that the combining weights must be determined with the greatest care.

The exact definition to be given to the term combining weight is not a matter of paramount importance, for it is evident that whether we call the combining weight of an element the smallest mass of it which combines with 1 part by weight of hydrogen, or 8 parts of oxygen, or 35·5 parts of chlorine, or whether we say that the combining weight is the L.C.M. of these numbers, or whether we take the expression to mean a whole multiple of this L.C.M., in any case the law holds good that the elements combine in the ratios of their combining weights or in ratios which bear a simple relation to these. What is required to be determined with the greatest care and accuracy is the ratio between the combining masses of every element and hydrogen, oxygen, chlorine, or other standard element; because this ratio, taken in conjunction with the definitions of atom and molecule, determines the value of the atomic weight of the element, and on this value depend many of the chemical properties of the element. In connexion with this article *v.* the arts. ATOMIC AND MOLECULAR WEIGHTS; COMBINATION, CHEMICAL, LAWS OF; FORMULÆ; NOTATION.
M. M. P. M.

COMBUSTION.—Any manifestation of chemical energy attended by combination and accompanied by production of much heat is, strictly speaking, an instance of combustion. As commonly used, however, the term carries with it the idea of *incandescence*; that is, the reacting bodies are not merely *incalescent*, but have their temperature raised to a point at which they emit light, or become self-luminous. This definition includes that of *inflammation*, which is, however, best restricted to instances of combustion in which the incandescent substances are gaseous. Such cases of combustion will be considered under FLAME.

All phenomena of burning are instances of combustion, and in the great majority of cases they consist in the union of the oxygen of the air with the substance which is being burnt, the visible signs of combustion, *i.e.*, the heat and light, being the result immediate or proximate of the chemical energy so expended.

It has been frequently observed that primitive communities regard as sacred all things that contribute to their existence or promote their well-being, and hence it is intelligible that a phenomenon so mysterious in its origin and process as fire, and at the same time so necessary to the welfare of mankind, should have been looked upon from the earliest times with particular reverence and awe. The evidence of fire worship is to be found probably in every religion. And it would be easy to show on strictly evolutionary principles how the idea of sanctity associated with the phenomenon of burning ramified and became interwoven into theories of the origin of life, of generation, and the nature of the soul and mind, and how it passed into the art of healing, and thence into the sciences which have sprung out of, or have been grafted on to, that art. The idea, but little shorn of its transcendental and spiritual attributes, is to be found in the earliest theories of chemistry. Fire plays such an important part in the operations of chemistry, the changes which it induces are so profound and extraordinary, burning and the evolution of heat by intrinsic agencies are so constantly witnessed as the result of chemical operations, that it is hardly surprising that the earlier chemists should have regarded combustion as the essential phenomenon of chemistry. A theory of combustion was to them also a theory of chemistry. Minds so sharply contrasted as those of Bacon and Boyle clearly apprehended the importance of a comprehensive theory of combustion from this point of view, but Bacon made no attempt to construct such a theory, and Boyle, in spite of his habitual caution, went singularly wrong in his efforts to explain the essential nature of fire and the phenomena we now recognise as due to oxidation. John Joachim Becher (1635–1682) has the credit of having first attempted to group all the facts of chemistry then known in such manner that they could be deduced from one general or universal principle. George Ernest Stahl (1660–1734) eagerly adopted Becher's fundamental idea, and amplified and worked it into a comprehensive system, capable of wide generalisation and fruitful of fresh lines of investigation. The theory of Becher and Stahl was essentially one of combustion. As it has exercised a very powerful influence on the development of chemistry, it may be desirable to sketch its main features with some degree of detail.

The theory as elaborated by Stahl is to be found in his *Fundamenta Chymiæ*, published in 1720, when its author was resident at Berlin as physician to the King of Prussia. It is not improbable that it was taught publicly at Halle between 1694 and 1716 when Stahl was Professor of Medicine at that University. Stahl defines chemistry as the art of resolving compounds into their constituents, and of recombining these constituents to again form the original or other compounds. According to Becher and Stahl, all combustible bodies are compounds, and in the act of burning they part with a constituent which is common to them all. This common principle was termed by Stahl *phlogiston* (φλογιστός = burnt). Bodies are combustible in proportion as they contain phlogiston; phosphorus, sulphur, charcoal, alcohol, sugar, the oils, resin, &c., are pre-eminently endowed with it. The metals also contain it, but in varying amount. When certain of the metals are strongly heated they are gradually converted into an earthy powder, termed a *calx*. The change which the metal had undergone was considered by Stahl as akin to ordinary combustion, and metals were regarded as compounds of calces, which were recognised as intrinsically dissimilar bodies, in union with the common principle, phlogiston, which was dissipated by the action of heat upon the metal. The re-conversion of the calx into the metal by processes which we now term reduction, that is by the action at a sufficiently high temperature of bodies like charcoal, coal, or by combustible gases, &c., was explained by Stahl as being due to the union of the phlogiston of the charcoal, &c., with the calx of the metal. It was noticed that many substances like phosphorus and sulphur on being burnt formed acids which when treated with a highly phlogisticated body such as charcoal gave rise to the original substances. Thus, phosphoric acid on being heated to a high temperature with charcoal formed phosphorus again. Hence phosphorus was considered to be a compound of phosphoric acid and phlogiston; in the act of burning the phlogiston was disengaged and the acid left; on restoring phlogiston to the acid the phosphorus was regenerated. Stahl sought to demonstrate the identity of the combustible principle in all substances by pointing to the fact that the calx of lead, for example, could be converted into the metal by the employment of phlogisticated bodies of such widely different properties as charcoal, sulphur, flour, sugar, iron, &c. As only one substance, viz., lead, was formed by the action of each of these bodies, it seemed to follow that they must all contain a common principle. In the same way it was pointed out that phosphoric acid could be changed into phosphorus by the action of a great variety of combustible bodies, such as lamp-black, resin, sugar, or even the metals. Of course it was known that many substances existed which were incombustible and were not sensibly changed by the action of fire, as, for example, lime, clay, rocks, &c.; such bodies were regarded as dephlogisticated by the action of previous heat, or as being incapable of combining with phlogiston. As the doctrine of phlogiston extended, the ideas of the phlogistic school respecting its essential nature became more and more vague. There seems to be no doubt, however, that Stahl and his immediate followers, Neumann, Pott, and Margraaf, in Germany, and Réaumur, Duhamel, and Macquer, in France, regarded phlogiston as a definite substance possessing all the essential attributes of matter. Stahl himself appears to have considered that phlogiston, when isolated, would turn out to be a solid earthy body insoluble in water like charcoal, sulphur, phosphorus, bitumen, and the metals. Indeed, as so many highly phlogisticated bodies were insoluble in water, while their dephlogisticated constituents, *e.g.*, phosphoric and sulphuric acids, were readily soluble, the property of solubility came to be regarded as dependent on or related to the presence or relative amount of phlogiston. Its presence or absence in fact affected all the properties of bodies, and caused all the changes they were capable of experiencing, as, for example, their relative stability, their capacity for union with other bodies, their acid or caustic characters, their colour, odour, and taste, and even their physiological and therapeutic activity. Many other natural phenomena, such as fermentation and decay, the growth of plants, and the processes of animal life, were also capable of explanation by the aid of the same general principle.

The doctrine of phlogiston was of incalculable service to chemistry. Indeed, it is not too much to say that Stahl's generalisation first raised chemistry to the dignity of a science. It not only served to present a simple and intelligible explanation of a mass of hitherto unconnected facts, but it pre-eminently fulfilled the function of every fruitful hypothesis by stimulating fresh inquiry and suggesting new lines of thought. Men like Black and Cavendish, whom we commonly reckon as phlogistians, were, however, not unmindful of its weaknesses, and Black certainly recognised its inadequacy to explain facts which he knew to be incontrovertible, such, for example, as the results obtained by Boyle on the calcination of metals. Boyle himself was doubtless aware of the doctrine in the form in which it was presented in Becher's *Physica Subterranea*, but it had probably no influence on his labours. Indeed he failed to perceive that much of his work was in direct opposition to Becher's teaching. His experiments on the calcination of lead and tin were interpreted by him as proving the materiality of heat, and it was reserved for Lavoisier and the so-called antiphlogistic school of French chemists to point out their real significance.

The doctrine of phlogiston was paramount in chemistry for upwards of half a century: the discovery of nitrogen by Rutherford in 1772, and of oxygen by Priestley in 1774, and the fuller recognition of the functions of these bodies in the air, by paving the way towards a clearer apprehension of the nature of combustion, brought about the downfall of Stahl's generalisation. Geber, upwards of ten centuries ago, had supplied chemistry with facts respecting the nature of calcination which the long subsequent labours of Sulzbach, Cardan, Rey, and Boyle had confirmed and strengthened. Hooke, in the *Micrographia*, and Mayow, in his *Opera Omnia Medicophysica*, pointed out that combustion consists in the union of something with the body which is being burnt, and Mayow, both by experiment and inference, demonstrated in the clearest way the analogy between respiration and combustion, and showed that in both processes one constituent only of the air is concerned; he distinctly stated that not only is there increase of weight attending the calcination of metals but that this increase is due to the absorption of the same *spiritus* from the air that is necessary to respiration and combustion. Mayow's experiments are so precise, and his facts so incontestable, that, as Chevreul has said, one is surprised that the truth was not fully recognised until a century after his researches. This recognition was forced upon the world by the experimental labours and writings of Lavoisier and his immediate followers in France. By repeating and extending the observations of Mayow, Black, Rutherford, and Priestley, Lavoisier proved that respiration, combustion, and calcination are essentially identical processes, in that they are primarily due to the action of oxygen—Priestley's dephlogisticated air—on the body undergoing change, and that the heat which is manifested is the result of the chemical change of which all these processes are examples. Lavoisier's experiments were so well devised and so admirably executed, his reasoning was so perspicuous and his proofs so irrefragable, that his conclusions seemed irresistible so far as the theory of combustion was concerned.

As Lavoisier's explanation of the true nature of combustion effected a complete revolution in the theory of chemistry, it may be desirable to trace the steps by which he was led to formulate it.

Lavoisier published in all some sixty memoirs, about half of which were concerned with the subject of combustion and of matters which immediately grew out of it. These appeared in different memoirs of the Academy between 1774 and 1788. It appears from his collected memoirs, published after his death in 1794, that his earliest experiments on the cause of the augmentation of weight which bodies experience during combustion and calcination were made in 1772.

In a memoir published in 1774 Lavoisier described a repetition of Boyle's experiments on the calcination of tin, in which he showed that during the formation of the calx a portion of the air disappears, and that the tin increases in weight in amount equal to the loss of weight experienced by the air. Hence he concluded that a portion of air had united with the tin, and that the calx of tin is composed of tin and air.

There is nothing in this memoir nor in the note of 1772 to indicate that Lavoisier had any idea of the compound nature of air. Still it is evident that he had advanced beyond the position of Boyle and Rey. Boyle inferred that his experiments proved the materiality of heat, while Rey appears to have imagined that the absorbed air was merely entangled with the metal.

In the autumn of 1774 Priestley exhibited to Lavoisier his method of making oxygen gas from the calx of mercury. In the following year appeared Lavoisier's memoir *On the nature of the principle which combines with the metals during their calcination and which augments their weight.* Starting from the fact that many of the metallic calces can be reduced by charcoal with the production of a gas which is identical with that produced by burning charcoal in the air, Lavoisier concluded that carbonic acid gas contains an elastic principle which is common to the air and the metallic calx. In the case of the calx of mercury he could obtain this elastic principle by heat alone. The gas so obtained was identical with Priestley's dephlogisticated air. Lavoisier surmised that this gas, which he, like Priestley, found to be pre-eminently a supporter of combustion and respiration, was probably contained in nitre, inasmuch as this salt when heated with charcoal forms large quantities of carbonic acid gas. Mayow, on other grounds, had already made the same supposition. This memoir was followed in 1777 by that *On the combustion of phosphorus and the nature of the acid which results from that combustion*, in which Lavoisier first distinctly recognised that the air was composed of two distinct substances, one of which was absorbed by the burning phosphorus to the extent of one-fifth of the original volume of air, while the other, originally termed by him *mouffette atmosphérique*, was incapable of supporting combustion or animal life, and was not absorbable by metals when heated, and hence was not concerned in the process of calcination. In the same year he published a paper *On the combustion of candles in atmospherical air, and in air eminently respirable*, in which he demonstrates that the *mouffette atmosphérique*, or *azote* as it is now called, plays no part in the burning of the candle, but that the combustion is entirely due to the dephlogisticated air or oxygen. Although Lavoisier's theory of combustion and of calcination was now practically complete, and was fully developed by him in his memoir *On combustion in general* in 1778, it made comparatively little impression even in France, and gained no converts of note until 1785, when Berthollet and Fourcroy gave in their adhesion to the new doctrine. The death-blow to phlogiston really came from the discovery of the compound nature of water. It was only after Cavendish's experiments on the combustion of hydrogen that Lavoisier was able to combat the generally received opinion as to the nature of the process of solution of metals in acids. It was observed that when certain metals were dissolved in acids, hydrogen was evolved, and the metals were converted into calces which could be again transformed into the metals by heating in hydrogen. These facts were accounted for by the Stahlian hypothesis on the assumption that the gas evolved on the solution of the metal was actually phlogiston, and that on heating the calx with the gas the phlogiston again combined with it to regenerate the metal. In 1783 Lavoisier was informed by Blagden, who at that time acted as Cavendish's assistant, of the experiments of the latter, made in 1781, on the production of water by the combustion of hydrogen. The importance of the discovery of the true chemical nature of water was at once perceived by Lavoisier. He and Laplace repeated Cavendish's experiment in presence of Le Roi and Blagden, and found that water was composed of 1 vol. of oxygen and 1·91 vol. of hydrogen. Further evidence of the compound nature of water was obtained by passing steam over red-hot iron contained in a porcelain tube, when free hydrogen was formed together with a calx of iron. Lavoisier was now able to explain the origin of the hydrogen in the act of solution of a metal in a dilute acid, on the assumption that in the process water was decomposed, and that the oxygen united with the metal to form the calx, while the hydrogen escaped in the free state. This view is further developed in the memoir *On the solution of the metals in acids*, published in 1785. Finally, in an elaborate paper *On Phlogiston*, Lavoisier connects together his various observations, elaborates his own theory of combustion, and confutes the phlogistic hypothesis.

Whatever may be thought of Lavoisier's claims to be considered the discoverer of oxygen, and of the true nature of air and water, there can be no question as to his merit in being the first to recognise the relation of these discoveries to the theory of combustion. As far back as 1772 he seems to have been fully persuaded of the insufficiency of the Stahlian hypothesis, and for upwards of a dozen years he laboured, practically alone, to demonstrate its insufficiency. His triumph was complete in 1785, and *La Chimie Française*, as the new doctrine was termed by Fourcroy, was embraced in France with all the fervour of revolution. Nor did national prejudice long delay its adoption in Germany and Great Britain. The Berlin Academy pronounced against phlogiston in 1792. Black early became a convert, but both Cavendish and Priestley, in spite of the fact that their discoveries had contributed so largely to its downfall, remained faithful to Stahl's doctrine to the end—an exemplification of the truth of Priestley's words that 'We may take a maxim so strongly for granted, that the plainest evidence of sense will not entirely change, and often hardly modify, our persuasions; and the more ingenious a man is, the more effectually he is entangled in his errors, his ingenuity only help-ing him to deceive himself by evading the force of truth.'

T. E. T.

In connexion with Combustion *v.* OXIDATION and DEOXIDATION.

COMENAMIC ACID *v.* DI-OXY-PYRIDINE CARBOXYLIC ACID.

OXY-COMENAMIC ACID *v.* TRI-OXY-PYRIDINE CARBOXYLIC ACID.

COMENIC ACID $C_6H_4O_5$. S. above 6 at 100°. Got by boiling meconic acid $C_7H_4O_7$ with HCl, CO_2 coming off. Purified by crystallising the difficultly soluble ammonium salt from water (How, *A.* 80, 65; *Ed. Phil. Trans.* 20 [2] 225; *cf.* Robiquet, *A. Ch.* [2] 51, 326; 53, 428; Liebig, *A.* 7, 287; 26, 116; Stenhouse, *P. M.* [3] 25, 196). Comenic acid is thrown down as a white powder when HCl is added to a solution of its ammonium salt.

Properties.—Prisms, laminæ, or granules; sol. boiling water, insol. alcohol. At 260° it splits up into CO_2 and pyromeconic acid. Fe_2Cl_6 gives a red colour. Does not react with hydroxylamine (Odernheimer, *B.* 17, 2081).

Reactions.—1. *Sodium-amalgam* reduces it to syrupy hydrocomenic acid $C_6H_8O_5$, which forms a salt $Ag_2C_6H_6O_5$ (v. Korff, *A.* 138, 191).—2. If comenic acid is boiled with PCl_5 (4 equivalents) and $POCl_3$ until no more HCl comes off, and the liquid distilled till the thermometer reaches 150°, an oil remains in the retort which is converted by boiling water into di-chloro-comanic acid, $C_5HCl_2O_2.CO_2H$ (yield, 20 p.c.). It crystallises from alcohol in needles, [217°]. Some chloro-comanic acid, $C_5H_2ClO_2.CO_2H$, [247°] is formed at the same time. Both acids are reduced by boiling conc. HI to comanic acid, $C_5H_3O_2.CO_2H$ (*q.v.*). When comanic acid is boiled with aqueous NH_3 it is converted into (β)-oxy-picolinic (oxy-pyridine carboxylic) acid. 3. Heated with PCl_5 at 280° it gives C_5Cl_8 or 'perchloro-mecylene,' and hexachloro-ethane. Perchloro-mecylene crystallises from alcohol in compact oblique prisms, melting at [39°] (Ost, *J. pr.* [2] 27, 294).—4. *Ethylamine* gives di-oxy-ethyl-pyridine carboxylic acid, $C_5HEtN(OH)_2CO_2H$.—5. *Aniline* gives similarly di-oxy-phenyl-pyridine carboxylic acid (H. Ost, *J. pr.* [2] 29, 380).

Salts.—NH_4HA''aq: four-sided prisms; reddens litmus. V. sol. boiling water.—K_2A'': sl. sol. water.—KHA'': short square needles; reddens litmus.—$NaHA''$: four-sided prisms (from hot water).—BaA''aq (at 121°).—BaA''5aq: insol. boiling water.—$BaH_2A''_2$6aq: sol. water.—CaA''aq (at 121°).—CaA''6½aq: prisms, insol. water.—CaA''3½aq.—$CaH_2A''_2$7aq: crystals, v. sol. hot water.—MgA''5½aq: crystalline grains.—$MgH_2A''_2$8aq.—CuA''aq (at 100°).—$Fe(OH)H_2A''_2$2aq (at 100°).—PbA''aq.—$AgHA''$: granular pp.—Ag_2A'': thick yellow pp.

Ethyl ether $C_5H_2O_2(OH).CO_2Et$. [135°] (How); [127°] (Reibstein). From an alcoholic solution of the acid and HCl. Formed also by heating meconic acid with EtI and alcohol at 100°. Needles, v. sol. hot water. May be sublimed. Fe_2Cl_6 gives a red colour. Very readily saponified. By successive treatment with sodium-amalgam and chloroformic ether a compound $C_{11}H_{12}O_7$ [87°] may be got (Drechsel, *J. pr.* [2] 17, 164).

Acetyl derivative of the ether $C_5H_2O_2(OAc)(CO_2Et)$. [104°]. From the above and Ac_2O at 150° (Reibstein, *J. pr.* [2] 24, 277).

Ethyl derivative $C_5H_2O_2(OEt)CO_2H$. [240°]. Obtained by fusing the ethyl derivative of meconic acid (*q.v.*) by itself. Crystallised from water, animal charcoal being used, it forms long white needles (Mennel, *J. pr.* [2] 26, 458).

Salt.—AgA'2½aq: white needles.

Amide $C_5H_2O_2(OH)(CO.NH_2)$. Formed by passing NH_3 into an ethereal solution of ethyl comenate. A pp. of $C_5H_2O_2(ONH_4)CO_2Et$ is first formed, but this is then slowly converted into $C_5H_2O_2(ONH_4)CO.NH_2$, whence HCl liberates the amide. White plates (from water). Not affected by boiling water. Boiling NaOH converts it into sodic comenate. Its aqueous solutions give a red colour with Fe_2Cl_6.

Salt.—$C_5H_2O_2(OK)(CO.NH_2)$ aq. Insol. alcohol.

Chloro-comenic acid $C_5HClO_2(CO_2H)(OH)$ 1½aq. Formed by passing Cl into water in which powdered comenic acid is suspended (How, *Ed. Phil. Trans.* 20 [2] 225). Four-sided prisms (from water). More soluble in water than comenic acid, v. e. sol. warm alcohol.—Ag_2A'' (at 100°).—$AgHA''$½aq.

Bromo-comenic acid $C_5HBrO_2(CO_2H)OH$. Formed by the action of bromine-water on comenic or meconic acids. Four-sided prisms; less soluble than the preceding body. Boiling baryta-water gives oxy-comenic acid.—$AgHA''$ (at 100°).—$AgHA''$½aq.

Ethyl ether EtA'. [141°]. From silver bromo-comenate and EtI. Glittering needles (Mennel, *J. pr.* [2] 26, 472).

Di-bromo-comenic acid

$C_5HBrO_2(OBr)(CO_2H)$ (?).

Formation.—From Br and bromo-comenic acid.

Preparation.—Meconic acid (10 g.) is suspended in water (80 g.) and bromine (18 g.) is added. The product separates at once as crystalline plates (containing 3aq).

Properties.—Its solution gives no colour with Fe_2Cl_6 in the cold, a red colour appears on heating, bromo-comenic acid being formed. At 105° the crystals give off Br (2 mols.) and H_2O. An aqueous solution of the acid gives no pp. with $BaCl_2$, but on adding NH_3 a red colour and an orange pp. are got. Zn and HCl reduce it to bromo-comenic acid.

Constitution.—This acid is not a true di-bromo-comenic acid, nor a compound of comenic or bromo-comenic acid with HBrO, hence it probably contains bromine in hydroxyl, although this is very unusual (Mennel, *J. pr.* [2] 26, 466).

Ethyl ether $C_5HBrO_2(OBr)(CO_2Et)$. From mono-ethylic meconate (10 g.), water (80 g.) and bromine (18 g.). Small yellowish tablets (containing 2aq). Sol. water, alcohol, and ether. Readily decomposes. When heated with water or with SO_2 it changes to white needles of bromo-comenate of ethyl [141°] (*v. supra*).

Nitro-comenic ether $C_5H(NO_2)(OH)CO_2Et$. [147°]. From HNO_3 (S.G. 1·5) and comenic ether in the cold. Better by passing N_2O_3 into an ethereal solution of ethyl comenate (R.). Sol. hot water, alcohol, and ether. Its aqueous solutions give with Fe_2Cl_6 a red colouration.

Salts.—$C_5H(NO_2)(ONa)CO_2Et$. Yellow needles. Explodes when heated.—$\{C_5H(NO_2)CO_2Et\}_2O_2Ba$. Explodes when heated. Silver salt blackens even when cold.

Amido-comenic acid $C_5H(NH_2)O_2(OH)CO_2H$. Formed by reduction of nitro-comenic ether by Sn and HCl (R.). Slender silky needles (containing aq) (from water). Sl. sol. alcohol and ether. Its aqueous solutions give a blue colour with a little Fe_2Cl_6, more Fe_2Cl_6 turns the liquid red.

Salt.—$C_5H(NH_2)O_2(OH)CO_2H,HCl, 3aq$. Glittering scales, formed by adding conc. HCl to the above. Decomposed by water, losing HCl.

Oxy-comenic acid $C_5HO_2(HO)_2CO_2H$. From bromo-comenic acid by boiling baryta, or with HCl (R.). Also from comenamic acid, $KMnO_4$, and dilute H_2SO_4. Crystallises from water in long needles (with 3aq) or in short prisms (with aq). V. sol. water and alcohol, sl. sol. ether. In its aqueous solution Fe_2Cl_6 gives a blue colour turned red by excess. NH_3 at 100° gives tri-oxy-pyridine carboxylic acid.

Salts.—$C_5HO_2(HO)_2CO_2NH_4$.—$\{C_5HO_2(OH)_2CO_2\}_2Ba, 2aq$.—$C_5HO_2(OK)_2CO_2K$.

Ethyl ether $C_5HO_2(HO)_2CO_2Et$. [204°]. Small prisms (from alcohol).

Di-acetyl derivative of the ether $C_5HO(OAc)_2CO_2Et$. [75°]. Small needles (from alcohol).

COMPOSITION, CHEMICAL. By the chemical composition of a compound is meant, primarily, a statement of the masses of the elements by the combination of which a specified mass—say 100 parts—of the body has been produced, or into which a specified mass of the body may be resolved. So long as nothing more than the percentage elementary composition of compounds was determined, chemistry remained a collection of unclassified facts. The establishment of the law of multiple proportions, and the development of this law, and also that of combining weights, led to the possibility of assigning to each compound a certain number which expressed the smallest relative mass of it that entered into chemical reactions with other compounds; but no generally applicable method for determining the values of these chemically reacting masses was found until the help of the atomic and molecular theory had been sought (*v.* COMBINATION, CHEMICAL, LAWS OF; and COMBINING WEIGHTS OF ELEMENTS). The composition of the smallest chemically reacting mass is expressed by the formula of the compound, which tells the number of combining weights of each elementary constituent which have combined to form the mass in question. This wider meaning of chemical composition rests on, and arises from, the laws of chemical combination; but it became definite only when supplemented by atomic and molecular conceptions.

The atomic weights of all the elements have been determined with more or less accuracy; when the molecular weight of a compound is known, the chemical composition of that compound is expressed in a formula which states the number of atoms of each element that have combined to form a molecule of the compound (*v.* ATOMIC AND MOLECULAR WEIGHTS). In this further widening of the conception of chemical composition, the properties of a compound are represented as determined by the nature and number of the atoms which form the molecule of the compound. This conception rests on, and arises from, the molecular and atomic theory.

It frequently happens, especially among compounds of carbon, that two or more compounds have the same composition and the same molecular weight, and yet differ in properties; such compounds are said to be isomeric. These differences in properties are generally regarded as associated with differences in the arrangement or configuration of the atoms which form the molecules of the compounds in question. More or less conventional methods are used for expressing the supposed relations between the properties of isomeric compounds and the structures of their molecules. These methods are based on the hypothesis of atomic valency which has arisen from the application of the molecular and atomic theory to the study of isomerism (*v.* EQUIVALENCY; FORMULÆ; ISOMERISM).

The term *chemical constitution* (*q. v.*) is often used to express that conception of chemical composition which includes an attempt to exhibit the properties of a compound as determined not only by the nature and number, but also by the relative arrangement, of the atoms which form the molecule of the compound.

In the preceding paragraphs it has been assumed that the composition of every element is always the same. As a matter of fact many bodies which were once regarded as elements have been proved to be compounds; and recent researches show that this process is likely to be repeated on some of those kinds of matter which are now classed among the elements. Be this however as it may, it is certain that some elements exhibit different properties when they are obtained from their compounds under different conditions. Phosphorus, carbon, oxygen, sulphur, and several other elements, exist in more than one form; they exhibit the phenomenon of allotropy. What we have learned of the connexions between properties and composition shows that these differences in properties are to be regarded as associated with differences in composition. The only consistent conception which can be formed at present of variations in the composition of elements is that which is furnished by the molecular and atomic theory According to this conception, the properties of an element depend not only on the nature of its atoms, but also on the numbers of these atoms which are combined to form a molecule, and on the relative arrangement of the atoms in the molecule (*v.* ALLOTROPY, vol. i. p. 128).

M. M. P. M.

COMPOUND RADICLES. The study of chemical composition and properties has led to the conception that certain groups or collocations of atoms in the molecules of various compounds remain so closely associated throughout chemical changes which the molecules undergo, that the functions performed by those groups of atoms in these reactions are practically identical with the functions performed by elementary atoms. Such groups of atoms are called *compound radicles* in distinction to the atom of an element which may be called a *simple radicle*. When two elements combine we may say that the compound is formed of two simple radicles;

e.g. NaCl is formed of the radicles Na and Cl; when two compounds combine to form what is generally called a *double compound* or a *double salt*, which double compound is easily resolved into the compounds by whose union it was formed, we may say that the double compound is formed of two compound radicles, each of which can be isolated. Similarly, when a compound goes through a series of reactions with the production of new compounds, all of which contain certain elements of the original compound, we may suppose that these certain elements were in some way closely associated in the original compound, and although we cannot isolate this group of elements, yet we may advantageously regard the original compound and those produced from it as formed by the union of this collocation of elementary atoms, or this compound radicle, with other atoms. The conception of the compound radicle is only a widening of the conception of the element; it is closely associated with the subjects of *chemical classification* and *chemical constitution* (*q.v.*). In connection with this subject *v.* RADICLE and TYPES, vol. iv.

M. M. P. M.

CONCHIOLIN *v.* PROTEÏDS, *Appendix C.*

CONCUSCONIDINE *v.* CINCHONA BASES.

CONCUSCONINE *v.* CINCHONA BASES.

CONESSINE $C_{12}H_{20}N$. [121½°]. Probably identical with *wrightine* (Stenhouse, *Ph.* [2] 5, 493; Haines, *Ph.* [2] 6, 432; Warnecke, *Ar. Ph.* [3] 26, 248, 281), which occurs in the bark and seeds of *Wrightia antidysenterica*, called conessi bark; occurs in the bark of *Holarrhena africana* (P. a. S.), and (though in much smaller quantity) in the East-Indian *H. antidysenterica* (Polstorff, *B.* 19, 1682). White silky needles. V. sol. alcohol, ether, benzene, and chloroform, v. sl. sol. water. Very bitter taste. Scarcely volatile with steam. Tertiary base. H_2SO_4 and dilute KIO_3 form oxy-conessine $C_{60}H_{103}N_5O_6$ (?), a base which is coloured rose-red by conc. H_2SO_4 at 100° (W.).

Salts.—B'HCl aq: small very soluble needles. $B'HNO_3$: needles.—B'HCl.—$B'_2H_2Cl_2PtCl_4$ ½aq: very sparingly soluble yellowish-red needles.—$B'HClAuCl_3$ 1¾ aq: long yellow needles, v. sol. alcohol, nearly insol. water.—$B'HCl,AuCl_3$ 3½aq: golden-yellow needles.—$B'HClHgCl_2$: needles, sl. sol. water.

Picrate $B'C_6H_2(NO_2)_3OH$ aq: very slightly soluble glistening golden needles.

Methylo-iodide $C_{12}H_{20}NMeI$ 1½aq: tables. V. e. sol. hot water.

Ethylo-iodide $C_{12}H_{20}NEtI$ ½aq: glistening tables.

Methylo-hydroxide $C_{12}H_{20}NMe(OH)$: strongly alkaline base formed by the action of Ag_2O upon the iodide. It readily absorbs CO_2 forming the carbonate $(C_{12}H_{20}NMeO)_2CO4aq$, which crystallises in long needles. On heating to c. 150° it splits up into conessine and MeOH (Polstorff a. Schirmer, *B.* 19, 78).

CONGLUTIN *v.* PROTEÏDS.

CONGO-RED *v.* ***Amido-sulpho-naphthalene-azo-diphenyl-azo-naphthylamine sulphonic acid***, vol. i. p. 416.

CONHYDRIN *v.* CONIINE.

CONICEÏDINE *v.* CONIINE.

CONICEÏNE *v.* CONIINE.

CONIFERIN $C_{16}H_{22}O_8$. [185°]. S. (cold) ·51. $[\alpha]_D = -66\cdot9$ at 20° (*B.* 18, 1600).

Occurrence.—1. In the cambium of coniferous trees (Kubel, *J. pr.* 97, 243).—2. In small quantity in beet-root, and hence it gives rise to traces of vanillin sometimes found in beet-sugar (Lippmann, *B.* 16, 44).—3. In asparagus (*B.* 18, 3335).

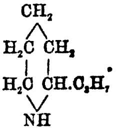
Preparation.—The juice of the cambial cells of fir trees is boiled, filtered, and evaporated to crystallisation.

Properties.—Satiny needles (containing 2aq). Efflorescent in dry air. V. sol. hot water, sl. sol. alcohol, insol. ether. Lævorotatory. Somewhat bitter. Its aqueous solution is not ppd. by metallic salts. Boiling dilute H_2SO_4 splits it up into glucose and a resin. Conc. H_2SO_4 gives a dark violet colour, and, on adding water, an indigo-blue pp. It is hydrolysed by emulsin into glucose and coniferyl alcohol. Phenol and H_2SO_4 give a blue colour, especially in sunlight. A dilute alcoholic solution of thymol and $KClO_3$ turns coniferin moistened with H_2SO_4 blue (Molisch, *C. C.* 1887, 366). Chromic mixture oxidises it to vanillin, giving the odour of vanilla (Tiemann). In weak alkaline solution sodium amalgam reduces it to eugenol (L. Chiozza, *C. C.* 1888, 443).

Tetra-acetyl derivative $C_{16}H_{18}Ac_4O_8$. [126°]. From coniferin and Ac_2O (Tiemann a. Nagai, *B.* 8, 1140). Crystalline. Insol. cold water, m. sol. cold alcohol and ether.

CONIFERYL ALCOHOL $C_{10}H_{12}O_3$ *i.e.* $C_6H_3(OH)(OMe)(C_3H_4OH)$. [4:3:1]. [74°]. Formed by subjecting an aqueous solution of coniferin to the action of emulsin at 25°: $C_{16}H_{22}O_8 + H_2O = C_6H_{12}O_6 + C_{10}H_{12}O_3$ (Tiemann a. Haarmann, *B.* 7, 611). Prisms. Sl. sol. hot water, m. sol. alcohol, v. sol. ether. Sol. alkalis and reppd. by acids in an amorphous condition, which softens at 160° and is v. sl. sol. alcohol and ether. This amorphous form is coloured red by conc. H_2SO_4, and afterwards dissolved with a red colour. Chromic acid mixture produces vanillin, which may be recognised by its characteristic odour; the other products of oxidation are HOAc and aldehyde. Potash-fusion gives protocatechuic acid. Sodium amalgam reduces it to eugenol $C_{10}H_{12}O_2$.

CONIINE $C_8H_{17}N$ *i.e.* $C_5H_{10}PrN$ or



Dextro-(α)-propyl-piperidine.

Mol. w. 127. (169°). S.G. $^{12\cdot5}$ ·846 (Petit, *B.* 10, 896); ·886 (Schorm). S. (cold) 1·11. S. (ether) 17. $[\alpha]_D = 13\cdot8$.

Occurrence.—In all parts of the hemlock (*Conium maculatum*) (Giesecke, Brande's *Ar. Ph.* 20, 97; Geiger, *Mag. Pharm.* 35, 72, 259; 36, 159; v. Planta a. Kekulé, *A.* 89, 129).

Synthesis.—(α)-Allyl-pyridine (from (α)-picoline and paraldehyde) on reduction with sodium and alcohol gives (α)-propyl-pyridine hexahydride; this (α)-propyl-piperidine is identical in all its properties with coniine, except that it is optically inactive, but by means of the acid tartrate it can be separated into a dextro- and a lævo-base, the former of which is identical with natural coniine (Ladenburg, *B.* 19, 2579).

Formation.—1. By heating conhydrine with HI and phosphorus, and treating the resulting hydriodide of iodo-coniine with tin and HCl (Hofmann, *B.* 18, 5).—2. By reducing (*a*)-coniceïne with HI and P (Hofmann).

Preparation.—100 kilos. of hemlock seeds, after soaking in hot water till swollen, are mixed with a solution of 4 kilos. of Na_2CO_3 in 4 litres of water, and the mixture distilled with steam of about 3 atmospheres. The aqueous distillate is neutralised with HCl evaporated, NaOH added and extracted with ether. The residue after distilling off the ether is fractionated. Another method consists in extracting the ground seeds *in vacuo* with dilute acetic acid, evaporating the solution to a syrup *in vacuo*, adding magnesia, and extracting with ether (Schorm, *B.* 14, 1765; *cf.* Wertheim, *A.* 100, 328; 123, 157).

Properties.—Oil, smelling like mice. Is a violent paralytic poison which acts on the motor nerves (Hofmann, *B.* 14, 705; *cf.* Christison, *J. Ph.* 22, 413; *J. Chim. Med.* 12, 461; Kuhlmann, *N. Br. Arch.* 23, 38). For white mice the lethal dose is ·0758 g. per kilo., whilst ·0750 g. does not produce death (Ladenburg). Its aqueous solution becomes turbid on warming. Volatile with steam. Alkaline to moist test-papers. Coniine (100 pts.) dissolves water (25 to 30 pts.) and the solution when heated becomes turbid from separation of water. V. sol. alcohol, ether, chloroform, benzene, amyl alcohol, and acetone; sl. sol. CS_2. Coniine dissolves S but not P. Coniine gives a yellow pp. with phosphomolybdic acid, a cheesy pp. with potassio-mercuric iodide, and an orange pp. with potassio-bismuthic iodide. If coniine is dropped into a solution of alloxan, an intense-purple red colour is gradually developed, while white needles separate, which dissolve in cold KOHAq forming a purple solution (Schwarzenbach, *cf.* W. Blyth, *Poisons*, 1884, p. 251). Chloride of iodine gives a dark yellow pp. Coniine does not dissolve $CaCl_2$.

Estimation.—Cripps, *Ph.* [3] 18, 511.

Reactions.—1. *Oxidises* readily in the air, becoming brown.—2. Boiling *chromic mixture* evolves *n*-butyric acid (Blyth; Grünzweig, *A.* 162, 193).—3. Alcoholic solution of *iodine* forms a dark brown pp. which afterwards disappears, the liquid becoming colourless.—4. *Bromine* forms a mass of needles [c. 100°]; if too much bromine is used a gummy mass is formed (Blyth).—5. *Chlorine* gas produces a turbidity in moist coniine.—6. Nitrous acid gas produces 'azoconhydrine' $C_8H_{16}N_2O$ (Wertheim, *A.* 123, 157).—7. By prolonged treatment with HI coniine is reduced to octane and NH_3 (Hofmann, *B.* 18, 5).—8. By distillation with *zinc-dust* it loses hydrogen and is converted into propyl-pyridine (conyrine) (Hofmann, *B.* 17, 825).—9. By the action of *bromine in alkaline solution* it gives a very unstable bromo- derivative which probably has the formula $C_8H_{16}NBr$. If this bromo- derivative is treated with H_2SO_4 it yields (*a*)-coniceïne $C_8H_{13}N$ with splitting off of HBr. If however the elimination of HBr from the bromo- derivative is produced by treating it with alkalis (γ)-coniceïne is obtained (Hofmann, *B.* 18, 109).—10. Reacts with *aldehydes* thus: $2C_8H_{16}NH + CH_3.CHO = (C_8H_{16}N)_2CH.CH_3 + H_2O$ &c. (Schiff, *B.* 6, 143).—11. *Chloroformic ether* forms $C_8H_{16}N.CO_2Et$ (245°). This is an oil, lighter than water, and very stable (Schotten, *B.* 15, 1947).—12. *Phenyl cyanate* forms the anilide of the same coniine *ν*-carboxylic acid $C_8H_{16}N.CO.NHPh$, which is v. sol. alcohol, ether, and benzene (Gebhardt, *B.* 17, 3041).—13. *Phenyl thiocarbimide* forms $C_8H_{16}N.CS.NHPh$ [88°] (G.).—14. *Phthalic anhydride* forms $CO_2H.C_6H_4.CO.N.C_8H_{16}$ [155°] the coniine salt of which when heated at 210° gives amorphous $C_6H_4{:}C_2O_2{:}(NC_8H_{16})_2$ (Piutti, *G.* 13, 558; *A.* 227, 181).

Salts.—B'HCl: [218°]. Colourless deliquescent laminæ. Dry HCl is said to colour dry coniine blue.—$B'_2H_2PtCl_6$: orange crystalline powder.—B'HBr: [100°] (Mourrut, *Ph.* [3] 7, 23). Trimetric needles; $a{:}b{:}c = {\cdot}8876{:}1{:}{\cdot}4218$.—B'HI: flat monoclinic prisms; $a{:}b{:}c = 1{\cdot}2112{:}1{:}1{\cdot}1532$ (Schorm, *B.* 14, 1765).—$B'HI_3$: octahedra (Baur, *Ar. Ph.* [3] 5, 214).—**Oxalate** $B'_2H_2C_2O_4$: small crystals.—**Tartrate** $B'C_4H_6O_6$2aq: large trimetric crystals; $a{:}b{:}c = {\cdot}7766{:}1{:}{\cdot}5859$.

Combination.—$B'2HgCl_2$: lemon-yellow pp. (Blyth).—$B'H_2S$ (?). Unstable (Schmidt, *B.* 7, 1525).

Benzoyl derivative $C_8H_{16}NBz$. Thick oil. On oxidation with $KMnO_4$ it yields the benzoyl-derivative of homo-coniic acid—$C_7H_{15}NBzCO_2H$ (Schotten a. Baum, *B.* 17, 2548).

Nitrosamine $C_8H_{16}N.NO$. *Azoconhydrine.* (150°–160°). From coniine by treatment with nitrous acid gas, followed by water (Wertheim, *A.* 123, 157; 130, 269). Yellow oil. V. sol. alcohol and ether. HCl passed into its ethereal solution reproduces coniine, giving off N and NO; zinc and HCl do the same.

Methyl-coniine $C_8H_{16}NMe$. From coniine and MeI. Formed also, together with C_2H_4 and H_2O, by distilling its ethylohydroxide (Kekulé a. Planta, *A.* 89, 143). Liquid.

Ethylo-hydroxide $C_8H_{16}NMeEtOH$. From the preceding by successive treatment with EtI and moist Ag_2O (K. a. P.). Strongly alkaline base.—$C_8H_{16}NMeEtI$: crystalline powder, not affected by aqueous KOH.—$C_8H_{16}NMeEtCl3HgCl_2$.—$(C_8H_{16}NMeEtCl)_2PtCl_4$: yellow octahedra.—$C_8H_{16}NMeEtAuCl_4$.

Methylo-hydroxide $C_8H_{16}NMe_2OH$. From coniine by treatment with excess of MeI, the resulting iodide being decomposed by moist Ag_2O.

Di-methyl-coniine $(C_8H_{15}Me)NMe$. (182°). Prepared by the dry distillation of the methylo-hydroxide of methyl-coniine. Liquid.—$(B'HCl)_2PtCl_4$: sparingly soluble needles.

Methylo-iodide $C_8H_{15}MeNMe_2I$: crystalline solid.

Methylo-hydroxide $C_8H_{15}MeNMe_2OH$: on dry distillation it splits up into H_2O, CH_3OH, NMe_3, di-methyl-coniine, and conylene (C_8H_{14}) (Hofmann, *B.* 14, 708).

Ethyl-coniine $C_8H_{16}NEt$. From coniine and EtI, the resulting $C_8H_{16}NEtHI$ being decomposed by KOH (K. a. P.). Oil, smelling like mice.—$(C_8H_{16}NEt)_2H_2PtCl_6$: yellow crystalline powder.

Ethylo-iodide $C_8H_{16}NEt_2I$. Crystalline mass. Gives $(C_8H_{16}NEt_2Cl)_2PtCl_4$.

Oxy-ethyl coniine $C_8H_{16}N.CH_2.CH_2OH$. (241°). The hydrochloride is formed by the action of glycol chlorhydrin on coniine.

Benzoyl derivative $C_8H_{16}N.CH_2.CH_2.OBz$. From BzCl and the above.—$B'HI$: small pearly plates.—$B'HCl$: very soluble crystals (Ladenburg, *B.* 14, 2409; 15, 1144).

Tri-bromo-oxy-coniine $C_8H_{14}Br_3ON$. Obtained as a by-product in the preparation of (γ)-coniceïne by treatment of coniine with bromine and alkali. Formed by the action of bromine and alkali upon (γ)-coniceïne (Hofmann, *B.* 18, 121). Heavy oil. Very unstable. The free base quickly decomposes spontaneously into the hydrobromide and di-bromo-oxy-coniceïne $2C_8H_{14}Br_3ON = C_8H_{14}Br_3ON,HBr + C_8H_{13}Br_2ON$. On reduction with tin and HCl it gives coniine and (γ)-coniceïne.

Salts.—$B'HBr$: needles.—$B'HNO_3$: very sparingly soluble.—$B'_2H_2Cl_2PtCl_4$: nearly insol. yellow crystalline pp.—$B'HClAuCl_3$: crystalline solid.

Di-methyl-oxy-coniine $C_8H_{15}Me_2ON$. (226°). Formed by the dry-distillation of the hydroxide of the ammonium-base $C_8H_{16}MeON,MeOH$, the iodide of which was obtained by digesting (γ)-coniceïne with methyl iodide and alcoholic NaOH (Hofmann, *B.* 18, 117). Colourless liquid. Sl. sol. water. Strongly alkaline.—$B'HCl,AuCl_3$: sparingly soluble crystals.

Homo-coniic acid $C_8H_{17}O_2N$ *i.e.* $CH_3.CH_2.CH_2.CH(NH_2).CH_2.CH_2.CH_2.CO_2H$ (?). [158°]. Obtained by saponification of the benzoyl derivative (Baum, *B.* 19, 502). White crystals; v. sol. water and alcohol. The aqueous solution reacts neutral. Optically inactive. Is not poisonous. It readily loses H_2O, and is converted into the inner-anhydride. When treated with nitrous acid it evolves nitrogen.

Benzoyl derivative $C_7H_{15}NBz.CO_2H$. [143°]. Formed by oxidation of benzoyl-coniine with $KMnO_4$ (Schotten a. Baum, *B.* 17, 2549). Needles or prisms; sol. alcohol, nearly insol. water and ether.—$A'Ag$: nearly insoluble white amorphous pp.—A'_2Cu: blue amorphous pp.; sl. sol. hot water, insol. alcohol.

Ethyl ether $C_7H_{15}NBz.CO_2Et$. [95°]. Long white flat prisms; v. sol. alcohol, ether, &c., nearly insol. water and petroleum-ether (Baum, *B.* 19, 500).

Inner anhydride $C_8H_{15}ON$. [85°]. Readily formed by splitting off H_2O from the acid by heating it to its melting-point, treating it with absolute alcohol, &c. (B.). White crystals. V. sol. water, alcohol, ether, and chloroform; m. sol. petroleum-ether. Sublimable. It is reconverted into the acid by boiling with baryta-water and ppg. the Ba with CO_2.

(α)-Coniceïne $C_8H_{15}N$. [c. −16°]. (158°). V.D. = 4·31 (obs.). S.G. ^{15} ·893.

Formation.—1. Together with (β)-coniceïne, by heating conhydrine $C_8H_{17}ON$ with P_2O_5.—2. Together with the (β)-coniceïne, by heating conhydrine with HCl.—3. By the action of H_2SO_4 on the bromo- derivative $C_8H_{16}NBr$ obtained by treating coniine with bromine and NaOH. The yield is 40 p.c. of the coniine—4. Together with (β)-coniceïne, by heating iodo-coniine $C_8H_{16}IN$.

Properties.—Colourless liquid. Sl. sol. water. Its odour is extremely like that of coniine. Tertiary base of strongly alkaline reaction. Its physiological action resembles that of coniine, but it is about five or six times as poisonous. By HI and P it is reduced to coniine.

Salts.—$B'HCl$: six-sided tables.—$B'_2H_2Cl_2PtCl_4$: large yellow trimetric prisms.—$B'HClAuCl_3$: yellow needles.—Picrate $B'C_6H_2(NO_2)_3OH$ [225°]: yellow needles; sl. sol. cold alcohol, nearly insol. water.

Methylo-iodide $B'MeI$: crystalline solid; very sol. water and alcohol.—$(B'MeCl)_2PtCl_4$: yellow pp. (Hofmann, *B.* 18, 5).

(β)-Coniceïne $C_8H_{15}N$. [41°]. (168°). Formed together with (α)-coniceïne (1) by heating conhydrine $C_8H_{17}ON$ with P_2O_5, (2) by heating conhydrine with fuming HCl, (3) by heating iodo-coniine $C_8H_{16}IN$ above 100°. Colourless needles. Very volatile. Coniine-like odour. Secondary base of strongly alkaline reaction. Weaker poison than the (α)-coniceïne.

Salts.—$B'HCl$: colourless, very soluble prisms.—$B'HClAuCl_3$.

(γ)-Coniceïne $C_8H_{15}N$. (173°). Obtained by the action of aqueous alkali upon the bromo-derivative $C_8H_{16}NBr$ formed by treatment of coniine with bromine in alkaline solution; the yield is 30 p.c. of the coniine. Colourless liquid. Not solid at −50°. Volatile with steam. About 12 times more poisonous than coniine. Sl. sol. water. Strongly alkaline. Lighter than water. Secondary base. By further treatment with bromine and alkali it is converted into tri-bromo-oxy-coniine $C_8H_{14}Br_3ON$. By digesting with methyl-iodide and alcoholic NaOH it yields the methylo-iodide of oxy-di-methylo-coniine $C_8H_{15}Me_2ONMeI$.

Salts.—$B'_2H_2Cl_2PtCl_4$: large crystals; S (at 20°) 2·4.—$B'HClAuCl_3$: sparingly soluble crystals.—$B'_2H_2Cl_2SnCl_4$: large crystals, the most characteristic salt of the base.

Acetyl derivative $C_8H_{14}NAc$ (252°–255°); oil (Hofmann, *B.* 18, 111).

Oxy-coniceïne $C_8H_{15}ON$ (210°–220°). Formed by reduction of di-bromo-oxy-coniceïne with tin and HCl (Hofmann, *B.* 18, 125). Colourless fluid. Volatile with steam. By digestion with alcoholic KOH it loses H_2O and is converted into coniceïdine $C_{16}H_{26}N_2$.

Salts.—$B'HCl$: colourless needles.—$B'HClAuCl_3$: easily soluble thick needles. The stannic double chloride is sparingly soluble.

Di-bromo-oxy-coniceïne $C_8H_{13}Br_2ON$. Formed by spontaneous decomposition of tri-bromo-oxy-coniine, thus: $2C_8H_{14}Br_3ON = C_8H_{14}Br_3ON,HBr + C_8H_{13}Br_2ON$. Prepared by shaking the tri-bromo-oxy-coniine hydrobromide with aqueous NaOH and ether. By tin and HCl it is reduced to oxy-coniceïne (Hofmann, *B.* 18, 124).

Coniceïdine $C_{16}H_{26}N_2$. [56°]. (above 300°). Colourless needles. Sol. alcohol and ether. Formed by elimination of H_2O from oxy-coniceïne by digesting it with alcoholic KOH.

Salts.—$B'HCl$: small sparingly soluble tables.—$B''H_2Cl_2PtCl_4$: nearly insoluble needles (Hofmann, *B.* 18, 126).

Conhydrine $C_8H_{17}NO$. *Oxy-coniine.* [121°]. (225°) at 720 mm. Accompanies coniine in hemlock seeds (Wertheim, *Sitz. W.* 47 [2] 299). Glittering plates (from ether). M. sol. water, v. sol.

alcohol and ether. Alkaline. Does not react with nitrous acid. Is a weak narcotic poison.

Reactions.—1. By the action of P_2O_5 it is not converted, as Wertheim (*A.* 127, 75) supposed, into coniine, but into a mixture of (*a*)- and (*β*)-coniceïne $C_8H_{13}N$. These products are also formed by heating conhydrine with strong HCl (Hofmann, *B.* 18, 5).—2. By heating with HI and P it is converted into an iodo-coniine $C_8H_{16}IN$, which on heating above 100° is converted into the hydroiodides of (*a*)- and (*β*)-coniceïne, and is reduced by tin and HCl to coniine.—3. PBr_3 converts it into a bromo-coniine $C_8H_{16}BrN$.

Salt.—$B'_2H_2PtCl_6$: red crystals. The sulphate is also crystalline.

Ethyl-conhydrine $C_8H_{16}EtNO$. Formed by the action of KOH on the crystalline compound of conhydrine with EtI. Oil.

Ethylo-iodide $C_8H_{16}EtNOEtI$. Trimetric crystals; *a*:*b*:*c* = ·8823:1:·105 (Zepharovich, *Sitz. W.* 47 [1] 275). Converted by Ag_2O into a caustic ethylo-hydroxide, whence HCl and $PtCl_4$ give $(C_8H_{16}EtNOEtCl)_2PtCl_4$: dimetric crystals; *a*:*c* = 1:·870.

Paraconiceine $C_8H_{15}N$. *Paraconiine.* Mol. w. 125. (169°). S.G. $\frac{0}{}$ ·913; $\frac{90}{}$ ·842.

Formation.—1. By heating butyric aldehyde with alcoholic NH_3 and distilling the resulting dibutyraldine (Schiff, *A.* 157, 352; 166, 88; *B.* 5, 42).—2. From butylidene chloride $CH_3.CH_2.CH_2.CHCl_2$ (or bromide) and alcoholic NH_3 at 180° (Michael a. Gundelach, *Am.* 2, 172; *B.* 14, 2105).

Properties.—Yellow liquid, smelling like coniine. V. sol. alcohol and ether; sl. sol. water. The aqueous solution becomes turbid when warmed. Inactive. As poisonous as coniine. Chlorine water produces in the aqueous solution a white pp., sol. HCl. The hydrochloride, when evaporated, becomes violet. Iodine dissolved in KI gives a brown pp. Is a tertiary base?—$B'_2H_2PtCl_6$: orange crystals.

'Paradiconiine' $C_{16}H_{27}N$. (210°). S.G. $\frac{15}{}$ ·915. Formed, together with paraconiceine, by the prolonged action of alcoholic NH_3 on butyric aldehyde. Its salts are amorphous.

CONIMENE $C_{15}H_{24}$. (264°). An essential oil obtained by steam-distillation from conima or incense-resin (called also Gum Hyawa), the produce of *Icica heptaphylla* (Stenhouse a. Groves, *C. J.* 29, 175).

CONQUINAMINE *v.* CINCHONA BASES.

CONQUINENE *v.* CINCHONA BASES.

CONQUININE *v.* CINCHONA BASES.

CONSTITUTION, CHEMICAL (*cf.* COMPOSITION, CHEMICAL).—The conception of chemical constitution is a development of that of chemical combination. All our present notions on the subject of constitution are essentially molecular and atomic. We cannot, indeed, express our conceptions of chemical constitution without using the language of the molecular theory. The chemical molecule is regarded as a definite structure built up of atoms, or groups of atoms, which are related to one another in a definite, although as yet unknown, way. The properties of the molecule are regarded as conditioned by the nature and number of the atoms, and also by the relations between the atoms, which form the molecule. Our only method of expressing the relations which undoubtedly exist between the parts of molecules is based on supposing these relations to be essentially space-relations. We try to picture the molecule as a configuration of parts, each of which bears a definite space-relation to each other, while all are capable of performing regulated motions without the disruption of the molecule.

This conception of the molecule as a structure is developed in the hypothesis of valency, and attempts are made to give consistent representations of it, with the help of certain conventions, in constitutional or structural formulæ (*v.* EQUIVALENCY; FORMULÆ; ISOMERISM).

M. M. P. M.

CONTACT ACTION *v.* CHEMICAL CHANGE.

CONVALLAMARIN $C_{23}H_{44}O_{12}$. Occurs, together with convallarin, in the lily of the valley (*Convallaria majalis*) from which plant it may be extracted by alcohol (Walz, *N. Jahrb. Pharm.* 1858, 10, 145; Langelbert, *J. Ph.* [5] 10, 26; *C. J.* 48, 271). Powder, with bitter taste, v. sol. water and alcohol, v. sl. sol. ether. Decomposed by boiling dilute H_2SO_4 into glucose and convallamaretin, which separates in crystalline spangles, and becomes resinous in boiling water.

Convallarin. Rectangular columns. Insol. water and ether, v. sol. ether. Resolved by boiling dilute acids into glucose and convallarin.

CONVICIN *v.* VICIN.

CONVOLVULIN $C_{31}H_{50}O_{16}$. [150°]. Occurs in tuberose or officinal jalap root (from *Convolvulus Schiedanus*), and may be extracted from jalap resin by washing with ether, then exhausting with alcohol, and evaporating the alcoholic extract (Mayer, *A.* 95, 161; A. F. Stevenson, *Ph.* [3] 10, 644). A hard resin. Odourless, tasteless. Sol. chloroform, and hydro-chloric acid; insol. water, ether, light petroleum, CS_2, benzene, and oil of turpentine. After being taken internally it is not secreted unaltered (Dragendorff, *C. C.* 1886, 589). Dissolves in H_2SO_4 to a bright red colour. Potassium chromate, permanganate, nitrate, or chlorate give an odour of rancid butter and an olive green colour. Conc. HNO_3 gives oxalic acid and ipomic acid $C_{10}H_{18}O_4$.

Convolvulic acid $C_{31}H_{52}O_{17}$ (?) [100°-120°]. Formed by boiling convolvulin with baryta-water (Kayser, *A.* 51, 81; Mayer, *A.* 83, 126; 95, 162). White hygroscopic substance; sol. water and alcohol, insol. ether.

Salts.—$KA'\frac{1}{2}aq$: [100°-110°]; amorphous.—BaA'_2.—PbA'_2.

Convolvulinolic acid $C_{26}H_{48}O_6aq$. [39°]. Formed, together with glucose, by the action of emulsin or of dilute acids on convolvulic acid. Minute needles: v. sl. sol. water, v. e. sol. alcohol, m. sol. ether. Tastes bitter. Conc. H_2SO_4 turns it red. Conc. HNO_3 gives oxalic and ipomic acids. The same body, or an isomeride, is formed by fusing convolvulin or convolvulic acid with moist NaOH. It forms salts: BaA'_2aq (at 100°).—PbA'_2.—$CuA'_2\frac{1}{2}aq$ (at 100°).

CONYLENE *v.* OCTINENE.

CONYLENE BROMIDE *v.* DI-BROMO-OCTYLENE.

CONYLENE GLYCOL *v.* DI-OXY-OCTYLENE.

CONYRINE is (*a*)-PROPYL-PYRIDINE (*q. v.*).

COPAIBA BALSAM. Exudes from incisions in the stems of various species of *Copaifera.* Diuretic.

It contains a lævorotatory terpene (**Copaiba oil**) $C_{20}H_{32}$ (250°-260°); S.G. ·9; V.D. 9·5. The terpene from ordinary copaiba balsam yields a crystalline hydrochloride $C_{20}H_{32}4HCl$ [77°], but those from Maracaibo balsam do not (Bonastre, *J. Ph.* 11, 529; Ader, *J. Ph.* 15, 95; Gerber, Brande's *Arch.* 30, 157; Blanchet, *A.* 7, 156; Soubeiran a. Capitaine, *J. Ph.* 26, 70; *A.* 34, 321; Posselt, *A.* 69, 67; Lowe, *Ph.* 14, 65; Strauss, *A.* 148, 151). The terpene from Maracaibo balsam yields terephthalic acid on oxidation (Brix, *M.* 2, 507). Moist copaiba oil distilled over sodium gives a dark blue hydrate $C_{20}H_{32}\frac{1}{3}aq$ (252°-260°). The different varieties of copaiba balsam also contain resins and resinous acids (Stoltze, *Jahrb. f. Pharm.* 27, 179; Oberdörfer, *Ar. Ph.* [2] 44, 172; Ulek, *Ar. Ph.* 122, 14; Stockhardt, *Ar. Ph.* 38, 12; Procter, *Ph.* 10, 603; Roussin, *J. Ph.* [4] 1, 321; Schweizer, *P.* 17, 784; 21, 172; Rose, *P.* 33, 83; Hess, *A.* 29, 140; Fehling, *A.* 40, 110; Wayne, *Am. Journ. Pharm.* [4] 3, 326; Siebold, *Ph.* [3] 8, 250; Bowman, *Ph.* [3] 8, 330; Martin a. Vigne, *J. Ph.* 1842, 52). On oxidation with $K_2Cr_2O_7$ and H_2SO_4 copaiba balsam yields *u*-di-methyl-succinic acid [140°] (Levy, *B.* 18, 3206).

Copaivic acid $C_{20}H_{32}O_2$ (?) Extracted by alkalis from copaiba balsam (Rose, *A.* 13, 177; 40, 310; Flückiger, *J. pr.* 101, 235; Rush, *Ph.* [3] 10, 5). Crystalline.—CaA'_2.—PbA'_2.—AgA'.

Metacopaivic acid $C_{22}H_{34}O_4$. [206°]. Extracted by alkalis from Maracaibo balsam obtained from Columbia (Strauss, *A.* 148, 153). Plates. Insol. water, v. sol. alcohol and ether.—$CuA''aq$.—$Ag_2A''aq$.

Oxycopaivic acid $C_{20}H_{28}O_3$. [c. 120°]. Found in a balsam from Para (Fehling, *A.* 40, 110). Crystals. Forms an amorphous hydrate $C_{20}H_{30}O_4$. PbA'_2.—AgA'.

COPAL. This name is given to a variety of resins which exude from different trees, *e.g. Rhus copallina*, *Elæocarpus copalifer*, *Hymenæa verrucosa*, *Dammara australis*. They contain many resins, and often yield terpenes on distillation (Filhol, *A.* 44, 323; Thomson, *A.* 47, 351; Schibler, *A.* 113, 339; Unverdorben, *B. J.* 11, 265; Violette, *C. R.* 63, 461; Muir, *C. J.* 27, 733; Rennie, *C. J.* 39, 240). A similar substance (copalin) is found fossilised at Highgate (Johnston, *P. M.* [3] 14, 87).

COPELLIDINE *v.* Tri-methyl-pyridine hexahydride.

COPPER GROUP OF ELEMENTS. Copper, Silver, Gold. These metals occur native; they have been known and used from very early times. They show a general resemblance to each other in their physical and chemical properties, but there are differences between them. The table in the next column presents some of their properties.

The three metals are hard, lustreus, malleable, tenacious, and ductile; they are good conductors of electricity; they crystallise in forms belonging to the regular system. Cu is oxidised by treating in air; Ag combines very slowly with O at extremely high temperatures; Au does not directly combine with O. Cu and Ag interact with acid to form salts; Au is acted on by *aqua regia*, but not by HClAq or HNO_3 separately. Cu decomposes steam at a red heat; Ag and Au are without action on steam.

General formulæ and character of compounds.—*Oxides*, MO and M_2O, also Au_2O_3. *Sulphides*, MS (except Ag), M_2S. *Haloid compounds*, MX_2 (except Ag), MX or M_2X_2, AuX_3. *Salts*, Cu_2X, Ag_2X, and a few Au_2X; CuX; a few Au_23X; ($X = SO_4, 2NO_3, CO_3, \frac{2}{3}PO_4, S_2O_3$, &c.). The oxides Cu_2O and Au_2O are produced by reducing cupric and auric salts, *e.g.* $CuSO_4Aq$ and $AuCl_3Aq$, in presence of an alkali; Ag_2O is obtained by adding alkali to an argentous salt, *e.g.* $AgNO_3Aq$. Addition of alkali to a cupric salt, *e.g.* $CuSO_4Aq$, ppts. $CuO.H_2O$, which loses water on heating to dull redness; addition of alkali to an auric salt, *e.g.* $AuCl_3Aq$, ppts. $Au_2O_3.3H_2O$, which loses water at 100°, and at a higher temperature becomes AuO; argentic oxide AgO is formed by the action of ozone on Ag_2O. Of the oxides of Cu, CuO is the more stable; it dissolves in acids and forms a large series of well-marked salts; Cu_2O forms a few salts by directly interacting with acids, but generally it reacts to form salts of CuO with separation of Cu. Of the oxides of Ag, Ag_2O is much the more stable; it reacts with acids to form argentous salts; AgO acts towards acids as a basic peroxide, forming argentous salts and evolving O. None of the oxides of Au is stable; a few salts corresponding to each are known, *e.g.* $Au_2S_2O_3$ derived from Au_2O, $AuSO_4$ from AuO, and $AuCl_3$ from Au_2O_3. The oxides of Cu and Ag are distinctly basic; moist Ag_2O acts like a weak alkali, although a hydroxide has not been certainly isolated. Au_2O and AuO are feebly basic; Au_2O_3 is also feebly basic, but it likewise dissolves in KOHAq to produce a salt, $KAuO_2$, in which Au forms part of the negative radicle.

The sulphides Cu_2S and Au_2S are produced by the combined action of H_2S and reducing agents on cupric and auric salts; *e.g.* a cupric salt heated in H_2S and then in H gives Cu_2S; $AuCl_3$ dissolved in KCNAq and ppd. by H_2S gives Au_2S. Argentous salts give Ag_2S on addition of H_2S. The sulphides CuS and AuS are formed by reactions between H_2S and cupric or auric salts. Both sulphides of Cu, and sulphide of Ag, are stable; Cu_2S being the more stable of the Cu sulphides. These sulphides are basic, forming some compounds with the sulphides of less positive elements, *e.g.* $Cu_2S.Sb_2S_3$; Cu_2S also forms some double compounds in which it appears to be negative to the other constituent, *e.g.* $K_2S.3Cu_2S.2CuS$. Au_2S when freshly ppd. dissolves in water; both this sulphide and AuS dissolve in alkali sulphides to form sulpho-salts, *e.g.* $NaAuS$, $KAuS_2$.

The salts of Cu belong to two series; *e.g.* Cu_2Cl_2 representative of cuprous salts, and $CuSO_4$ representative of cupric salts; the cupric salts are the more stable. Silver forms but one series of salts, the argentous salts, *e.g.* $AgNO_3$, Ag_2SO_4. Few gold salts are known; $Au_2S_2O_3$ is a representative of the aurous salts, $AuSO_4$ represents the auro-auric salts, and $AuCl_3$ belongs to the auric series. Auric chloride and bromide $AuCl_3$ and $AuBr_3$ combine with HCl and HBr respectively, forming the monobasic acids $HAuCl_4$ and $HAuBr_4$. Gold is distinctly the most negative of the three elements Cu, Ag, Au; the non-metallic character of Au is shown in the formation of aurates, *e.g.* $KAuO_2$, derived from Au_2O_3, of sulpho-aurates, *e.g.* $NaAuS$ and $KAuS_2$, derived from AuS, of the acids $HAuCl_4$ and $HAuBr_4$, and in the instability of the salts of Au. Silver is distinctly metallic in all its chemical relations. Cu is also metallic, but the formation of such compounds as $K_2S.3Cu_2S.2CuS$ shows a tendency of Cu to react as a feebly non-metallic element.

The position of the elements Cu, Ag, Au in the scheme of classification based on the periodic law is peculiar (*v.* CLASSIFICATION, p. 204). These elements are placed in Group I.; this group comprises Li, Na, K, Rb, and Cs, which are the most positive, and chemically the most metallic, of all the elements; but Cu finds a place in the *long period* containing the metals Fe, Ni, and Co; Ag comes in the *long period* which contains Rh, Ru, and Pd; and Au follows Os, Ir, and Pt. The three sections of Group VIII., viz. (1) Fe, Ni, Co, (2) Rh, Ru, Pd, (3) Os, Ir, Pt, appear to impress their own properties on the elements immediately preceding and succeeding them. Cu, Ag, and Au exhibit analogies at once with the other members of the group to which they belong, and with those metals of Group VIII. which form part of the *long periods* including Cu, Ag, and Au respectively. The analogies with the metals of Group VIII. are shown in the physical properties of Cu, Ag, and Au, and also to some extent in their general chemical characters. The analogies between the alkali metals and the elements of the Cu group are shown in the composition of the alkali salts and the cuprous salts, the argentous salts, and the few aurous salts which have been isolated; also in the basic character of cuprous, argentous, and aurous oxides. The existence of AgO and CuO_2, and the fact that these behave as peroxides, establishes an analogy between Cu and Ag on one side, and Na or K on the other; Ag also forms an alum, $Ag_2SO_4.Al_2(SO_4)_3.24H_2O$; moist Ag_2O reacts as a weak alkali; the non-existence of any salts of Ag except those of the type AgX ($X = \frac{SO_4}{2}, NO_3$, &c.) establishes another resemblance between Ag and the alkali metals. It should be noted here that the molecular formula of cuprous chloride is Cu_2Cl_2, while that of silver chloride is AgCl; in this point Ag resembles the alkali metals, as the molecular formulæ KCl and CsCl have been established. Au differs more than either Cu or Ag from the alkali metals; this difference is emphasised in the acidic characters of Au_2O_3, Au_2S, and AuS, in the formation of $HAuCl_4$, &c., and in the great instability of the salts of Au; on the other hand, the solubility in water of Au_2O and Au_2S suggests the solubility in water of the oxides and sulphides of the alkali metals. The methods of formation of Au_2O and Au_2S suggest the processes by which Cu_2O and Cu_2S are formed. (For more details about the metals of the copper group, *v.* COPPER, SILVER, GOLD; *v.* also NOBLE METALS.) M. M. P. M.

COPPER. Cu. At. w. 63·2. Mol. w. unknown (c. 1100°; for various determinations *v.* Carnelley's *Melting and Boiling Points*). S.G. varies from 8·36 for finely divided Cu to 8·95 for hammered Cu (*v.* Playfair a. Joule, *C. S. Mem.* 3, 57; Dick, *P. M.* [4] 11, 409; Baudrimont, *J. pr.* 7, 287; Hampe, *C. C.* 6, 379; Marchand a. Scheerer, *J. pr.* 27, 193, &c.). S.H. (15°–100°) ·0933; (16°–172°) ·0948; (17°–247°) ·0968 (Bède, *Mem. B.* 27 [1855–56]. C.E. (linear 0°–100°) ·00001666 (Matthiessen, *Pr.* 15, 220). C.E. (cubical) $V_t = V_0 (1 + \cdot00004443t + \cdot0000000555t^2)$ (Matthiessen, *l.c.*). T.C. (Ag = 100) 73·6 (Wiedemann a. Franz, *P. M.* [4] 7, 33). E.C. at c. 19° (Ag wire = 100), 93 (Matthiessen, *Tr.* 1860; *Pr.* 11, 126). E.C. at 0° (Hg at 0° = 100) c. 52–54 (Siemens, *P. M.* [4] 21, 24). E.C. is much decreased by small quantities of P, As, Zn, Fe, Sn, &c. (*v.* Matthiessen, *l.c.*). Emission-spectrum characterised by lines in the green 5217, 5153, and 5105 (Thalèn) Hartley (*Tr.* 1884. 105) gives the following as prominent lines of high refrangibility: 3273·2 3246·9, 2544·6, 2370·1, 2248·2, 2247·7, 2244, 2243·5. Crystallises in regular octahedra. S.V.S. c. 7·1.

Occurrence.—Very abundantly; as metal, oxide, sulphide, chloride, arsenate, carbonate, phosphate, sulphate, silicate, and vanadate. Small quantities of salts of Cu are found in seaweed (Malaguti, *A. Ch.* [3] 28, 129); in sea-water (Dieulafait, *A. Ch.* [5], 18, 349); in the blood of various animals (*v.* Harless, *Chem. Gazette*, 1848. 214; Genth, *P.* 95, 60; *J.* 1848. 871, 874; 1849. 530; Ulex, *J. pr.* 94, 376; Wicke, *W. J.* 1866. 73); in flour, eggs, &c. (Odling a. Dupré, *Guy's Hospital Reports*, October 1858); in all plants that live on primary rocks or on soil derived from these rocks (Dieulafait, *A. Ch.* [5] 19, 550). In many mineral waters. Copper has been known and used for making tools from very early times.

Formation.—1. From native oxides and carbonates by melting with silica in presence of lime and charcoal; silicate of calcium is formed and the charcoal reduces the oxide of copper.—2. From native sulphides, and sulphides of Cu with Fe, &c., by roasting and then melting; CuO is first formed, and then reacts with FeS in the ores to form CuS and Fe_2O_3, the greater part of the iron passes into the slag; by repeating this process approximately pure CuS is obtained; this is roasted so as to convert a part of it into CuO, the mixture of CuO and CuS is melted in closed apparatus when SO_2 and Cu are produced ($2CuO + CuS = 3Cu + SO_2$); the impure copper is refined by *poling*, a process consisting in stirring the melted metal, covered with a layer of anthracite, with a green pole of birch or oak, the heated wood evolves reducing gases (CO, H_2O, hydrocarbons).—3. From oxide, or from roasted native sulphides, by treatment with heated conc. NaClAq whereby $CuCl_2$ is formed and dissolved, followed by ppn. by means of scrap iron.—4. From oxide, or from roasted native sulphides, by treatment with hot NaClAq and $FeSO_4Aq$ mixed with $CaCl_2$ and subsequent ppn. by scrap iron; the chief reaction is $3CuO + 2FeCl_2Aq = Fe_2O_3 + Cu_2Cl_2Aq + CuCl_2Aq$. 5. By electrolysis of solution of Cu salts.

Preparation.—1. Commercial copper is dissolved in fairly conc. H_2SO_4Aq; $PbSO_4$ is ppd. by diluting largely with water; the liquid is filtered and poured on to Zn or Fe (sifted Zn powder is best), and digested until nearly but not quite colourless; the pp. is freed from Zn or Fe by treatment with warm dilute HClAq; it is then washed, dried, and fused under borax; or the pp. of Cu after digestion with acid is washed, dried quickly at 75°, and heated in a stream of H (Böttger, *A.* 89, 172). [For impurities in commercial copper *v.* Abel a. Field, *C. J.* 14, 280.]—2. $CuSO_4Aq$ is mixed with $KC_2H_3O_2Aq$, and H_3PO_4Aq is added; Cu ppts. quickly (Wöhler, *A.* 79, 128).—3. Commercial copper is dissolved in equal parts of H_2SO_4 and water; the solution is boiled with a little HNO_3 (to oxidise Fe salts) and crystallised, the crystals are recrystallised from water, dissolved and electrolysed (Millon a. Commaille, *C. R.* 56, 1249).—4. Hampe (*Fr.* 1874. 352) adds KOHAq to $CuSO_4Aq$ until a pp. of basic salt is formed (this pp. contains any Bi which might have been present in the $CuSO_4$); the filtered solution is evaporated and crystallised; the crystals are dissolved in the smallest possible quantity of water; 20 cc. conc. HNO_3Aq are added to every 500 cc. solution; an electric current is passed through this liquid using cone-shaped Pt electrodes, the current being stopped before the whole of the Cu is ppd., whereby Fe, Zn, and other metals remain in solution; the ppd. Cu is washed and dissolved in pure HNO_3Aq, the solution is evaporated to dryness, and the $Cu(NO_3)_2$ obtained is decomposed by heating; the CuO is reduced by heating in pure H. The Cu thus obtained is dissolved in H_2SO_4Aq; crystals of $CuSO_4$ are obtained, and the foregoing process of electrolysis is repeated. The metal obtained by the second electrolysis is boiled in water, to remove traces of undecomposed $CuSO_4$. The Cu thus obtained is heated to a very high temperature in a porcelain tube in a current of pure CO_2 (about 50 grams Cu at a time) until melted. H is then passed over the molten metal for a time, and finally it is allowed to cool in CO_2.—5. Finely divided Cu may be obtained (*a*) by reducing CuO in a stream of H; (*b*) by strongly heating a mixture of 5 parts Cu_2Cl_2 with 6 parts dry Na_2CO_3, and some NH_4Cl, and washing the product (Liebig a. Wöhler, *P.* 21, 582); (*c*) by digesting $CuSO_4Aq$ with sifted zinc powder, pouring off the liquid before quite colourless, washing the residue with dilute HClAq, pressing between paper, and drying at about 75°.

Properties.—A reddish-yellow solid. The red colour of ordinary Cu is due to a film of Cu_2O. Crystallises from molten state, or by slow electrolytic deposition, or by ppn. by means of P, in cubes and octahedra belonging to the regular system. Melts at high temperature, about 1100°; expands on solidifying; very ductile, malleable, hard, and elastic; fairly tenacious; very good conductor of heat and electricity; may be highly polished; sonorous. Copper melted in air assumes a vesicular structure on cooling owing to escape of bubbles of gas, either CO formed when the Cu is melted under charcoal, or SO_2 formed by action of traces of S in the Cu on traces of CuO present (Dick, *P. M.* [4] 11, 409; Matthiessen a. Russell, *P. M.* [4] 23, 81). Finely divided Cu may readily be hammered and pressed into masses. Cu is slightly volatile when very strongly heated (Riemsdyk, *C. N.* 20, 32); in the O-H flame it boils and partially volatilises; Despretz (*C. R.* 48, 362) volatilised Cu in a H stream by passing a current through it from 600 Bunsen-cells. Molten Cu absorbs various gases (Hampe, *Zeitschr. f. d. preuss. Berg-Hütten und Salinen Wesen*, 1874 a. 1875; Graham, *P. M.* [4] 32, 503; Lucas, *A. Ch.* 12, 402; Marchand a. Scheerer, *J. pr.* 27, 195; Dick, *P. M.* [4] 11, 409; Matthiessen a. Russell, *P. M.* [4] 23, 81; Lenz, *J. pr.* 108, 438). H is absorbed in considerable quantity (finely divided Cu absorbs ·6 vols. of H, Graham); the whole of the H is not given out on cooling, or on heating to 160° (Lietzenmayer, *B.* 11, 306); but if the Cu is heated to 250° it is slightly oxidised, and if it is then heated to redness in a nearly closed tube a little H_2O is formed, and the CuO is reduced (L., *l.c.*). Cu prepared by reducing CuO in H retains a little H, which may be removed by the method described; or by heating in a stream of formic acid vapour (Wegl, *B.* 15, 1139). SO_2 and CO are also absorbed by molten Cu; CO_2 and N are not absorbed. Cu in masses is unchanged in dry air; when gently heated it is superficially oxidised to Cu_2O, at a higher temperature Cu_2O and CuO are formed; finely divided Cu burns to CuO in air considerably under a red heat. In moist air containing CO_2, Cu becomes covered with a film of greenish basic carbonate; after a considerable time the interior of such Cu contains crystals of Cu_2O (*D. P. J.* 206, 200). Finely divided Cu, obtained by reducing CuO under red heat, is changed by ordinary air to Cu_2O. Cu in mass decomposes H_2O at a full red heat, and then only slowly. Cu is slowly acted on by many dilute organic acids in the air; eatables should not, therefore, be allowed to remain in Cu vessels exposed to air, although they may be boiled with water in such vessels, as then the escaping steam removes the air. Cu is slightly dissolved by HClAq or H_2SO_4Aq in presence of air; conc. hot H_2SO_4 forms $CuSO_4$ and CuS with evolution of SO_2; conc. hot HIAq forms Cu_2I_2 and H; HNO_3Aq readily dissolves the metal with evolution of N oxides; SO_2Aq slowly forms $CuSO_3$ and H_2SO_2Aq. NH_3Aq, in presence of O, acts on Cu, forming Cu-NH_4 nitrate; heated in NH_3, Cu nitride is formed. NH_4 salts, and some other metallic salts, in solution dissolve appreciable quantities of Cu. Cu combines directly with Cl, Br, S, P, Si, As, Sb, and many metals (*v.* COPPER, ALLOYS OF).

The atomic weight of Cu has been determined (1) by reducing CuO in H (Berzelius, *P.* 8, 182; Erdmann a. Marchand, *J. pr.* 81, 391; Millon a. Commaille, *C. R.* 57, 147; Hampe, *Fr.* 13, 351); (2) by electrolysing $CuSO_4Aq$ and weighing the Cu (Hampe, *Fr.* 13, 367; Shaw, *P. M.* [5] 23, 138); (3) by reducing $AgNO_3Aq$ by pure Cu and weighing the Ag (Richards, *P. Am. A.* 22; 23, 177). The number 63·2 is confirmed by the S.H. of Cu, and by comparison of the crystalline forms of Cu compounds with some ferrous compounds, and also with compounds of Co and Ni, and with some compounds of Ag.

Copper is distinctly a metallic element; it forms salts by replacing the H of most acids; most of these salts belong to the series CuX_2 where $X = Cl, NO_3, \frac{SO_4}{2}$, &c.; but several *cuprous* salts, Cu_2X_2, are also known. There are indications of the existence of compounds of Cu with strongly positive metals and O, in which the Cu forms part of the negative radicle of the salts, but such salts have not been isolated (*v.* COPPER, OXIDES OF). Copper is analogous in its chemical relations on one hand to Ag, and on the other to Fe, Ni, and Co; it also shows similarities with Au and with the alkali metals. In the periodic classification of the elements Cu is generally placed both in Group VIII., which comprises Fe, Ni, Co, and the Pt metals, and also in Group I., which includes H, the alkali metals, Ag, and Au (*v.* COPPER GROUP OF ELEMENTS). The valency of the atom of Cu has not been determined with certainty; the only compound whose molecular weight in the gaseous state has been determined is Cu_2Cl_2, the atom of Cu is most probably divalent in this molecule.

Allotropic form of copper. Schützenberger (*C. R.* 86, 1265) described a bronze-coloured solid, obtained by electrolysing a solution of Cu acetate containing some basic acetate (produced by boiling); the negative electrode consisted of a plate of Pt, and the positive of a somewhat larger Cu plate; 2 Bunsen- or 3 Daniell-cells were used; the electrodes were placed 3 or 4 centims. apart. The bronze-coloured body was deposited on the face of the Pt electrode turned towards the Cu plate. The deposit was lustrous; very brittle; S.G. c. 8 to 8·2; it contained 5 to 10 p.c. CuO; it was oxidised readily in moist air; cold HNO_3Aq (10 p.c.) dissolved it readily with evolution of nearly pure N_2O. This substance was changed to ordinary Cu by heat. No H was evolved by heating to 100° in CO_2. Wiedemann (*W.* 6, 81) says that the substance obtained by electrolysing Cu acetate as described is ordinary Cu containing CuO sometimes amounting to 35 p.c.; Schützenberger (*Bl.* [2] 31, 291) asserts that his *allotropic copper* is changed to ordinary copper without change of mass (*v.* also Mackintosh, *C. N.* 44, 279).

Reactions.—1. Cu decomposes *water* slowly at a full red heat (Regnault, *A. Ch.* 62, 364).—2. In dry *air* Cu is unchanged; but in ordinary moist air it becomes covered with a film of a basic carbonate (*D. P. J.* 206, 200), and crystals of Cu_2O are formed in the interior of the mass.—3. Heated in *oxygen* CuO is formed; very finely divided Cu is said to form Cu_2O in oxygen without heating.—4. Not acted on by *weak acids in absence of air*, but slowly dissolved by dilute HClAq, &c., in presence of air. Thomsen gives these thermal data (*Th.* 3, 320):—$[Cu, O^2, SO^3] = 111,490$; $[Cu, O^2, 2NO^2, 6H^2O] = 96,950$; $[Cu, O, H^2SO^4Aq] = 55,960$; $[Cu, O, 2HNO^3Aq] = 52,410$.—5. In very conc. *nitric acid* Cu is *passive*, because of formation of layer either of NO or CuO (*cf. Passivity of Iron*, under IRON). Dissolves rapidly in less conc. nitric acid giving off NO and N_2O.—6. Conc. *hydrochloric acid* in presence of air dissolves finely divided Cu, forming Cu_2Cl_2 and evolving H (Odling, *C. J.* 9, 291); less conc. HClAq slowly dissolves Cu when heated with it in presence of air.—7. Dilute *sulphuric acid* in presence of oxygen slowly dissolves Cu (forming H_2O_2 according to Traube, *B.* 18, 1887). Conc. H_2SO_4 acts on Cu even at 20°, forming Cu_2S, and $CuSO_4$; at higher temperatures SO_2 is evolved, until at 270° the action is represented by the equation $Cu + 2H_2SO_4 = CuSO_4 + SO_2 + 2H_2O$ (Pickering, *C. J.* [2] 18, 112).—8. *Sulphurous acid* slowly acts, forming sulphite and H_2SO_2Aq; if large excess of H_2SO_3Aq is used, CuS is formed along with S (Causse, *Bl.* [2] 45, 3).—9. Conc. hydriodic acid attacks Cu forming Cu_2I_2 and H.—10. Aqueous solutions of many *metallic salts* slowly dissolve Cu; chlorides and nitrates, especially of ammonium, are the most active (*v.* Pattison Muir, *C. N.* 34, 223, 234; Carnelley, *C. J.* [2] 15, 1). According to Traube (*B.* 18, 1887) Cu dissolves in $(NH_4)_2CO_3Aq$ with production of H_2O_2Aq.—11. *Ammonia solution* slowly dissolves Cu with previous formation of CuO; Schönbein (*B. B.* 1856. 580) says that Cu-NH_4 nitrite is produced. Heated in *ammonia* to full redness, Cu becomes brittle and now contains N, a nitride is probably formed (Warren, *C. N.* 55, 155).—12. *Sulphuretted hydrogen* forms CuS.—13. Many *fatty oils*, *e.g.* olive, rape, linseed, &c., dissolve considerable quantities of Cu (Thomson, *C. N.* 34, 176, 200, 213).

Combinations.—Copper combines directly with the following non-metallic elements either at the ordinary or higher temperatures: *chlorine*, *bromine*, *iodine*, *oxygen*, *sulphur*, *selenion*, *phosphorus*, *silicon*, *arsenic*, *antimony* (for details *v.* COPPER, CHLORIDE OF; BROMIDE OF, &c.). It is not quite certain whether Cu combines directly with *nitrogen* or not; Blondlot (*C. R.* 102, 210) got indications of combination when discs of Cu and Pt were strongly heated in an atmosphere of N (*cf.* COPPER, NITRIDE OF).

Detection and Estimation.—Cu salts in solution give a deep-blue colour with excess of NH_3Aq; a mahogany-coloured pp. of ferrocyanide of Cu in very dilute liquids. Minute traces of Cu may be detected by immersing a small couple of Zn and Pt wires in the liquid, and then exposing the Pt wire to the vapour given off by adding conc. H_2SO_4 to KBr; if a trace of Cu has been deposited on the Pt a deep-violet colour is produced, due to formation of a compound of $CuBr_2.xH_2O$ with HBr (Cresti, *G.* 7, 220). Copper is often estimated by ppn. with KOHAq, heating, and weighing as CuO; also by ppn. as metal by means of Zn and Pt. Volumetric methods of estimation are based on the reaction of ammoniacal Cu solutions with KCNAq to form colourless $Cu(CN)_2.2NH_4CN$; on the reaction of Cu solutions with KIAq to form Cu_2I_2, and I; on the reaction of Cu_2O with Fe_2Cl_6Aq to form $CuCl_2Aq$ and $FeCl_2Aq$; and on other reactions. Cu may also be estimated by electrolysis (*v.* Classen, *Quantitative Analyse durch Electrolyse* [Berlin, 1886]). For details of methods a *Manual of Analysis* must be consulted.

Copper, Alloys of.—Many alloys of Cu are much used in manufactures because of their malleability, hardness, and durability, and in some cases sonorousness. Only a brief account of the chief classes of these alloys is given here; for details of those alloys which are of especial technical importance reference must be made to the *Dictionary of Technical Chemistry*.

1. With aluminium. Alumina and CuO are strongly heated with carbon in about the ratio Al:9CuO:9C. The alloy which results has the composition Cu_3Al; it has the colour of gold, is very tenacious and malleable, very hard, and takes a high polish. This alloy, or an alloy containing from 5 to 10 p.c. Al, is generally known as *aluminium-bronze* (*v.* Debray, *C. R.* 43, 925).

2. With *antimony*. Cu and Sb alloy in almost all proportions. Compounds $SbCu_2$ and $SbCu_4$ probably exist (*v.* Ball, *C. J.* 53, 167). These alloys are brittle. Sb is present in many varieties of bronzes and in alloys for making parts of locomotives. For action of acids on alloys of Sb and Cu *v.* Calvert a. Johnson, *T.* 1858. 349.

3. With *arsenic*; *v.* COPPER, ARSENIDES OF.

4. With *bismuth*; various alloys are formed by heating the metals together; an alloy of 2 parts Bi with 1 part Cu expands after solidification (Marx, *S.* 58, 470).

5. With *gold* *v.* Roberts, *A. Ch.* [5] 13, 133.

6. With *iron*. Cu is alloyed with iron by fusion. (For description of alloys *v.* Mushet, *P. M.* (3) 6, 81.)

7. With *lead*. Cu and Pb melted together at a red heat form alloys; but the fused mass tends to separate into two layers; the upper containing much Cu and little Pb, and the lower much Pb and little Cu; separation is partly prevented by rapid cooling. Pb is found in many clock-metals and bronzes.

8. With *nickel*. Alloys of Cu and Ni, with about 10Cu and 4Ni, are nearly white; alloys containing Cu, Ni, and Zn are largely used under the names of *German silver*, *Packfong*, &c.

9. With *silver*; Cu and Ag alloy in very varied proportions (for details *v.* Roberts, *A. Ch.* (5) 13, 111).

10. With *tin*. The various bronzes, gun-metals, and bell-metals, are alloys of Cu and Sn; these alloys are formed by fusing the two metals together. Many bronzes contain Pb, and some contain small quantities of Fe and Sb. For details of the manufacture and properties of the copper-tin alloys *v. Dictionary of Technical Chemistry*. Two compounds of Cu and Sn appear to exist, Cu_4Sn and Cu_3Sn; the evidence is based on the variations in the specific gravities, electrical conductivities, and other physical properties, of the alloys of Cu and Sn (*v.* Matthiessen, *T.* 1860. 161; Riche, *C. R.* 55, 1862; Lodge, *P. M.* (5) 8, 554; Calvert a. Johnson, *T.* 1858. 349; Roberts, *P. M.* (5) 8, 58, 551; Laurie, *C. J.* 53, 104; Ball, *C. J.* 53, 167).

11. With *zinc* Ordinary brass is an alloy of about 2 parts Cu to 1 part Zn; many alloys of the two metals in various proportions are used in manufactures under the names of *Pinchbeck*, *Mosaic gold*, &c. Modern bronze is generally an alloy of Cu with *zinc* and *tin*. These alloys are formed either by fusing the metals together, or by heating Cu with ZnO and charcoal. In some cases one metal is ppd. on the other from solution. For details regarding the manufacture, properties, and uses of the various brasses, &c., *v. Dictionary of Technical Chemistry*. There are indications of the formation of a compound of Cu and Zn, *viz.* $CuZn_2$ (*v.* Laurie, *C. J.* 53, 104). For action of acids on Cu-Zn alloys *v.* Calvert a. Johnson, *C. J.* [2] 4, 435; also Matthiessen, *C. J.* [2] 4, 502.

Copper, Antimonate of. $Cu(SbO_3)_2.5H_2O$ (Fremy, *A. Ch.* [3] 12, 499; Heffter, *P.* 86, 418).

Copper, Antimonides of (*v.* COPPER, ALLOYS OF).

Copper, Arsenates of. $Cu_5H_2(AsO_4)_4.2H_2O$, and $Cu_3(AsO_4)_2$ (*v.* ARSENIC, ACIDS OF, vol. i. 308).

Copper, Arsenides of. The compounds Cu_3As, Cu_6As, and Cu_9As, occur native as *Domeykite*, *Algodonite*, and *Darwinite*, respectively. According to Lippert (*J. pr.* 81, 168) the grey deposit obtained by heating Cu in an HCl solution of As_2O_3 in Cu_5As_2; when this is heated in H, Cu_6As remains.

Copper, Arsenites of. $CuHAsO_3$, and $Cu(AsO_2)_2$; *v.* ARSENIC, ACIDS OF, vol. i. 306.

Copper, Boride of. When amorphous B is heated with Cu in a crucible for some hours, above the M.P. of Cu, a yellow, very hard, brittle, mass is obtained, S.G. 8·116; this is Cu_3B_2 according to Marsden (*C. J.* 37, 672).

Copper, Borofluoride of. $Cu(BF_4)_2$, *v.* under COPPER, FLUORIDES OF.

Copper, Bromides of. Two bromides are known, $CuBr_2$, and Cu_2Br_2 (or CuBr). The molecular weight of neither in the gaseous state has been determined; but judging from the chlorides the formulæ given are probably molecular. Thomsen gives the thermal values $[Cu^2,Br^2] = 49,970$; $[Cu,Br^2] = 32,580$; $[Cu^2Br^2,Br^2] = 15,190$; $[Cu,Br^2,Aq] = 40,830$ (*Th.* 3, 319).

I. CUPRIC BROMIDE, $CuBr_2$. (*Copper dibromide.*) Prepared by dissolving $Cu(OH)_2$ in HBrAq, or digesting Cu turnings with excess of BrAq, or adding KBrAq to $CuSiF_6Aq$; the green solution turns brown on evaporation; when the residue is gently heated, $CuBr_2$ remains as a graphite-coloured fusible mass. If the green solution is evaporated *in vacuo* over H_2SO_4, $CuBr_2$ is obtained in lustrous iodine-coloured crystals (Rammelsberg, *P.* 55, 246). By evaporating in air, Berthemot (*A. Ch.* 44, 385; *v.* also Löwig, *P.* 14, 485) obtained greenish-brown crystals of $CuBr_2.5H_2O$. $CuBr_2$ is deliquescent and very soluble in water; when heated it gives CuBr and Br. This bromide combines with ammonia to form $CuBr_2.5NH_3$ and $CuBr_2.3NH_3$; the former is a blue powder obtained by passing NH_3 over $CuBr_2$; the latter forms dark-green crystals, obtained by adding alcohol to $CuBr_2Aq$ saturated with NH_3 (Rammelsberg, *P.* 55, 246). These double compounds dissolve in water; on dilution $Cu(OH)_2$ is ppd.; when heated they give off NH_3 and NH_4Br and leave a mixture of $CuBr_2$ and CuO.

II. CUPROUS BROMIDE. Cu_2Br_2. (*Copper monobromide.*) Prepared by heating $CuBr_2$, by passing Br over heated Cu, or by reaction between Cu and $CuBr_2Aq$ mixed with $FeBr_2Aq$ (Renault, *C. R.* 59, 319). A white powder, insoluble in water. S.G. 4·72; M.P. = 504°; B.P. between 861° and 954° (Carnelley a. Williams, *C. J.* 37, 125). Not decomposed by conc. H_2SO_4, but by HNO_3Aq (Berthemot, *A. Ch.* [2] 44, 385; Löwig, *P.* 14, 485). Turns bluish in sunlight and is then less soluble than before in NaClAq or $Na_2S_2O_3Aq$ (Renault, *C. R.*, 59, 319).

Copper, Chlorides of. Two chlorides of copper are known, $CuCl_2$ and $CuCl$ or Cu_2Cl_2. Many experiments have been made on the V.D. of cuprous chloride; it is very probable that the molecular formula of this salt is Cu_2Cl_2. Thomsen gives the thermal data $[Cu^2,Cl^2] = 65{,}750$; $[Cu,Cl^2] = 51{,}630$; $[Cu, Cl^2,2H^2O] = 58{,}500$; $[CuCl^2,2H^2O] = 6{,}870$; $[Cu,Cl^2,Aq] = 62{,}710$ (*Th.* 3, 319).

I. Cupric chloride. $CuCl_2$. (*Copper dichloride.*)

Preparation.—1. By burning Cu in Cl gas, or by passing Cl over heated CuCl.—2. By dissolving Cu in *aqua regia*, or in boiling conc. HClAq in presence of air, or by dissolving CuO or $CuCO_3$ in hot HClAq; the green solutions thus obtained are evaporated and the crystals of $CuCl_2.2H_2O$ which form are heated to 100°.—3. By mixing NaClAq with $CuSO_4Aq$, evaporating, filtering from Na_2SO_4, evaporating, and heating the $CuCl_2.2H_2O$ obtained.

Properties and Reactions.—A brownish-yellow, deliquescent, solid; melts at red heat and gives CuCl and Cl. Easily soluble in water, solution in a very little water is dark-green (Solly, *P. M.*, 1843. 367); on addition of more water it becomes green, colour of very dilute solutions is greyish-blue (Gladstone, *C. J.* 8, 211, says that $CuCl_2.2CuO\,4H_2O$ is formed); addition of conc. HClAq or better H_2SO_4 produces a yellow colour in a green solution of $CuCl_2$. Franz (*J. pr.* [2] 5, 274) gives the following data showing the composition and S.G. of $CuCl_2Aq$:—

P.c. $CuCl_2$	S.G.	P.c. $CuCl_2$	S.G.
5	1·0455	25	1·2918
10	1·092	30	1·3618
15	1·1565	35	1·4417
20	1·2223	40	1·5284

$CuCl_2$ is soluble in alcohol and in ether; alcoholic solutions burn with green flame. $CuCl_2Aq$ ppd. by KOHAq yields various oxychlorides (*v.* Copper, oxyhaloid compounds of). For reactions of $CuCl_2$ with *metallic sulphides*, *v.* Rammelsberg (*C. J.* 39, 374), and Raschig (*A.* 228, 1).

Combinations. — 1. With *water* to form $CuCl_2.2H_2O$; obtained by evaporating solutions of $CuCl_2$ and crystallising (*v. supra*); rhombic prisms $a:b:c = {\cdot}9179:1:{\cdot}4627$ (*Gm.-K.* [6th ed.] 3, 642); lose $2H_2O$ at 100°, or over H_2SO_4 (*cf.* Vogel, *D. P. J.* 136, 239, with Graham, *A.* 29, 31).—2. With *ammonia* to form $M.2NH_3$, $M.4NH_3.H_2O$, and $M.6NH_3$ $[M = CuCl_2]$ (Kane, *A. Ch.* 72, 273; Rose, *P.* 20, 155). $CuCl_2.6NH_3$ is formed by passing NH_3 over $CuCl_2$ as long as absorption continues; when heated to 149°, NH_3 is evolved and $CuCl_2.2NH_3$ remains. When NH_3 is passed into hot conc. $CuCl_2Aq$ until the pp. which forms has re-dissolved, and the liquid is allowed to cool, $CuCl_2.4NH_3.H_2O$ separates in dark-green octahedra which lose NH_3 on drying.—3. With *ammonia and salammoniac* to form $CuCl_2.2NH_3.2NH_4Cl$; obtained by boiling Cu turnings with conc. NH_4ClAq till a deep-blue liquid is obtained, filtering from $Cu_2Cl_2.2NH_3$ which separates, allowing the filtrate to oxidise in the air until it becomes greenish, and cooling (Ritthausen, *J. pr.* 60, 376). Dark-green tablets, decomposed by water.—4. With *cuprous chloride and ammonia* to form $CuCl_2.Cu_2Cl_2.4NH_3.H_2O$ (Ritthausen, *J. pr* 60, 374); obtained by dissolving Cu_2Cl_2 in NH_3Aq, allowing the solution to become deep blue by exposure to air, and crystallising; or by the prolonged action of NH_4ClAq on Cu turnings at the ordinary temperature. Blue prisms; decomposed by water and alcohol; absorb O from air and lose NH_3; when heated leave Cu_2Cl_2; soluble in hot HClAq from which solution $CuCl_2.2NH_4Cl.2H_2O$ crystallises out.—5. With *ammonium chloride*, to form (a) $CuCl_2.2NH_4Cl.2H_2O$, and (b) $CuCl_2.NH_4Cl.2H_2O$. The former is obtained by crystallising a mixed solution of the two salts (Mitscherlich, *J. pr.* 19, 449; Graham, *A.* 29, 132); or by concentrating a mixed solution of $CuSO_4$ and NH_4Cl (Vogel, *J. pr.* 2, 194); or saturating $CuCl_2Aq$ with NH_3 (Cap a. Henry, *J. pr.* 13, 184). Light-blue rhombic tables, or octahedra; loses all H_2O at 110°–120°; S.G. 1·96 to 1·97. The salt $CuCl_2.NH_4Cl.2H_2O$ was obtained by Hantz (*A.* 66, 280), as blue-green crystals, by neutralising 1 part HClAq by NH_3 and 2 parts of the same HClAq by $CuCO_3$, mixing the solutions, and crystallising.—6. With *potassium chloride* to form $CuCl_2.2KCl.2H_2O$; obtained by evaporating a mixed solution of the two salts. S.G. 2·4.

II. Cuprous Chloride. Cu_2Cl_2. (*Protochloride of copper.*) Mol. w. 197·14. V.D. (c. 1560°) 6·8. Formula found to be Cu_2Cl_2 and not CuCl from results of V.D. determinations by V. and C. Meyer, at c. 1560° (*B.* 12, 1112, 1283). $[Cu^2, Cl^2] = 65{,}750$; $[Cu^2Cl^2, Cl^2] = 37{,}510$ (*Th.* 3, 319).

Formation.—1. Cu is heated in Cl, keeping the Cu in excess.—2. Cu is heated to dull redness in a stream of HCl (Wöhler, *A.* 105, 360).—3. By heating together $CuCl_2$ and Cu in HClAq.—4. By heating together Cu and Fe_2Cl_6Aq.—5. By heating $CuCl_2$.—6. By reducing $CuCl_2Aq$ or $CuSO_4Aq$ by $SnCl_2$, or SO_2.—7. By heating 2 parts $HgCl_2$ with 1 part Cu turnings.—8. By heating $CuSO_4$ with NaH_2PO_2 in a little water (Cavazzi, *G.* 16, 167).

Preparation.—1. Sulphur dioxide is passed into a mixture of 1 part NaCl and $2\frac{1}{8}$ parts $CuSO_4.5H_2O$ dissolved in water; the white pp. is washed with SO_2Aq, then with glacial acetic acid, pressed between paper, and dried at 100° (Wöhler, *A.* 130, 373; Rosenfeld, *B.* 12, 954). $[2CuCl_2Aq + H_2SO_3 + H_2O = Cu_2Cl_2 + H_2SO_4Aq + 2HClAq]$.—2. An intimate mixture of 14·2 parts powdered CuO with 7 parts zinc powder is thrown, little by little with constant shaking, into conc. HClAq, until a white pp. of Cu_2Cl_2 begins to form; more acid is added, and then a little more of the mixture, and so on until the whole of the mixture has been used. The liquid is then poured into boiled water in a flask so that the flask is filled; the flask is closed; the Cu_2Cl_2, which separates as a shining white solid, is washed with distilled water, and dried in the dark (Heumann, *B.* 7, 720). $[2CuO + Zn + 4HClAq = Cu_2Cl_2 + ZnCl_2Aq + 2H_2O]$.

Properties.—Snow-white crystalline powder; insoluble in water, alcohol, dilute HNO_3 or H_2SO_4Aq; soluble in hot HClAq, separating on cooling in tetrahedra; soluble in NH_3Aq; soluble, on heating, in KClAq, NaClAq, Fe_2Cl_6Aq, $ZnCl_2Aq$, and many other metallic chlorides; soluble in $Na_2S_2O_3Aq$ when the two salts are in the ratio $Cu_2Cl_2:Na_2S_2O_3$ (Winkler, *J. pr.* 88, 428). S.G. 3·7. Melts below red heat, and boils between 954° and 1032° (Carnelley a. Williams, *C. J.* 37, 126). Solution in HClAq acts as an energetic reducer, converting $HgCl_2$ to HgCl, $AuCl_3$ to Au, decolourising Prussian blue, &c.; this solution rapidly absorbs CO (*v.* Hempel, *B.* 21, 898; *cf.* Drehschmidt, *B.* 21, 2158), colourless crystals of $Cu_2Cl_2.CO.2H_2O$ separate from a saturated solution of CO in Cu_2Cl_2 (Berthelot, *A. Ch.* [3] 46, 488), on warming the solution CO escapes. This solution also absorbs various gases, *e.g.* C_2H_2 and PH_3 (Riban, *B.* 12, 1208; Rose, *P.* 4, 110; 6, 205).

Reactions.—1. Moist Cu_2Cl_2 changes in *sunlight* and *air* to yellow, violet, and then blue-black; an oxychloride is formed ($CuCl_2.3CuO$, according to Vogel, *D. P. J.* 136, 238) [concerning the action of sunlight on Cu_2Cl_2 *v.* Carlemann, *J. pr.* 63, 475].—2. Heated in *oxygen* or in *water-vapour*, CuO is formed.—3. By repeated washing with *water* $CuCl_2$ and Cu_2O are produced.—4. Reduced to Cu by *hydrogen*, or by digestion under water with *iron filings.*—5. Scarcely acted on by *sulphuric acid*, even when conc. and hot (Rosenfeld, *B.* 12, 954).—6. Reacts with many *metallic sulphides* to produce Cu_2S (*v.* Raschig, *A.* 228, 1).

Combinations.—1. With *ammonia* to form $Cu_2Cl_2.2NH_3$. By dissolving Cu_2Cl_2 in NH_3Aq; or better by boiling Cu turnings with conc. NH_4ClAq until rapid evolution of NH_3 begins, filtering the boiling liquid into ½ its volume of water, and repeatedly filtering from $Cu_2O.xH_2O$, allowing to cool, repeatedly washing the solid which separates with alcohol and quickly pressing between paper (Ritthausen, *J. pr.* 59, 369, Millon a. Commaille, *C. R.* 56, 309). Colourless rhombic dodecahedra, becoming violet in air; decomposed by water into its constituents on heating; solution in water reduces ammoniacal silver solutions (M. a. C.), it absorbs O from the air forming $Cu_2Cl_2.CuCl_2.4NH_3.H_2O$ (*q.v.* under Cupric chloride, *Combinations*, No. 4).—2. With *salammoniac* to form $Cu_2Cl_2.4NH_4Cl$. Obtained by dissolving $Cu_2Cl_2.2NH_3$ in HClAq, or by adding a little NH_3Aq to Cu_2Cl_2 in HClAq; white crystals, becoming brown in air, and giving Cu_2Cl_2 and NH_4Cl when heated (Ritthausen, *J. pr.* 59, 369).—3. With *potassium chloride* to form $Cu_2Cl_2.4KCl$; large octahedra; prepared by dissolving Cu_2Cl_2 in boiling KClAq, and allowing to cool in a closed vessel (Mitscherlich, *A. Ch.* 73, 384). A compound with NaCl is also known; it is very soluble and difficult to crystallise.—4. With *phosphorus hydride*, to form $Cu_2Cl_2.2PH_3$. Obtained, as long colourless needles, by passing PH_3 into Cu_2Cl_2 in HClAq until crystals form; when heated gives Cu phosphide, PH_3, and HCl; water forms PH_3 and Cu_6P_2 (Riban, *Bl.* [2] 31, 385).

Copper, Fluorides of. Two fluorides have been isolated, CuF_2 and Cu_2F_2 (Berzelius, *P.* 1, 28).

I. Cupric fluoride, $CuF_2.2H_2O$. Best obtained by dissolving $CuCO_3$ in HFAq, and adding alcohol of ·95 p.c. (Balbiano, *G.* 14, 74). Pale-blue crystalline powder; sparingly soluble in water, very easily decomposed to oxyfluoride $CuF_2.Cu(OH)_2[=CuF.OH]$ (*v.* *Oxyfluoride* under Copper, oxyhaloid compounds of). Decomposes on keeping for four or five days with evolution of HF. Combines with KF to form very soluble $CuF_2.2KF$. Absorbs NH_3 with formation of $CuF_2.Cu(OH)_2.4NH_3.2NH_4F.2H_2O$ (Balbiano, *l.c.*).

Cupric borofluoride $Cu(BF_4)_2[=CuF_2.2BF_3]$ is obtained by mixing $Ba(BF_4)_2$ and $CuSO_4Aq$.

Cupric silicofluoride $CuSiF_6.6H_2O$ is produced by dissolving CuO in H_2SiF_6Aq and evaporating.

II. Cuprous fluoride, Cu_2F_2. A red powder obtained by treating $Cu_2O.xH_2O$ with HFAq; washing with water, pressing, and drying *in vacuo*; decomposed by moist air to $Cu(OH)_2.CuF_2$ (Berzelius, *l.c.*).

Copper, Hydride of. A compound of Cu and H is said to be produced by the following reactions:—1. 1 pt. $Ba(H_2PO_2)_2$ is dissolved in water, the Ba is exactly ppd. by H_2SO_4Aq, the filtrate is added to ·8 parts $CuSO_4.5H_2O$ in rather dilute solution, at the ordinary temperature, ppn. is allowed to proceed slowly; the pp. is washed with air-free water in an atmosphere of CO_2, and dried by pressure between paper (Wurtz, *A. Ch.* [3] 11, 250; *C. R.* 89, 1066; 90, 22).—2. $NaHSO_2Aq$ is added in excess to $CuSO_4Aq$; if the $CuSO_4$ is in excess the pp. contains some Cu (Schutzenberger, *C. R.* 69, 196).—3. Zinc is placed in $CuSO_4Aq$ acidulated with H_2SO_4 (Schoor, *Ar. N.* 12, 96; [*J.* 1877. 273]).—4. A moderately strong current is passed through very dilute slightly acidulated $CuSO_4Aq$; the compound forms at the negative pole but begins to decompose, with evolution of H, as soon as the current is stopped (Poggendorff, *P.* 75, 337). Copper hydride is described as a reddish-brown powder, having the composition Cu_2H_2; it decomposes at 60° into Cu and H; in HClAq it gives Cu_2Cl_2 and H; it takes fire in Cl. (*Cf.* Berthelot [*C. R.* 89, 1005, 1097], who says that the so-called copper hydride always contains O, H_2O, and P; but Wurtz [*C. R.* 90, 22] gives further details and analyses, showing that the preparation is apt to contain Cu phosphate, but the presence of more than a mere trace of this may be avoided by ppg. the Cu_2H_2 very slowly in cold solutions.)

Copper, Hydroxides of, *v.* Hydrated oxides of Copper, under Copper, oxides of.

Copper, Iodides of. Only one iodide of copper has been isolated; this is the cuprous compound, Cu_2I_2. When KIAq is added to the solution of a cupric salt, a pp. of Cu_2I_2 mixed with free I is obtained; *e.g.* $2CuSO_4Aq + 4KIAq = Cu_2I_2 + I_2 + 2K_2SO_4Aq$. Cu_2I_2 dissolves in alcoholic solution of I; the liquid is not ppd. by water, but on heating and adding alcoholic solution of KI, Cu_2I_2 is ppd. along with KI_3. Solutions containing about 8 gram CuI_2 per 100 c.c. have been obtained; compounds are known which probably contain CuI_2 (*v. infra*).

Cuprous iodide, Cu_2I_2. S.G. 4·41 (Schiff). B.P. between 759° and 772° (Carnelley a. Williams, *C. J.* 37, 126). Mol. w. not determined, but from analogy of Cu_2Cl_2 it is probably Cu_2I_2 = 379·46. $[Cu^2,I^2]$ = 35,200 (*Th.* 3, 319).

Formation.—1. Finely divided Cu heated with I forms Cu_2I_2; a plate of Cu exposed to the vapour of I becomes covered with crystals of Cu_2I_2 (Renault, *C. R.* 59, 319).—2. Cu is dissolved in conc. HIAq, on standing in air (or better on adding a trace of H_2S) Cu_2I_2 ppts. in crystals (Rose, *P.* 4, 110).—3. Cu_2S is dissolved in conc. HIAq (Mensel, *B.* 3, 123).—4. KIAq is added to $CuSO_4Aq$; Cu_2I_2 is ppd. along with I.

Preparation.—$CuSO_4Aq$ is saturated with SO_2, or a mixture of 1 pt. $CuSO_4.5H_2O$ and 2¼ pts. $FeSO_4.7H_2O$ is dissolved in water, KIAq is added, the pp. is washed and dried (Duflos, *A.* 39, 253; Soubeiran, *J. Ph.* 13, 427).

Properties and Reactions.—A white, or brownish-white, crystalline powder; insoluble in water, alcohol, and dilute acids; soluble in KIAq, and in NH_3Aq in presence of air. Soluble in hot conc. HClAq and reppd. on addition of water. Decomposed by conc. HNO_3 or H_2SO_4. Heated with MnO_2 or $KClO_3$, CuO is formed; reduced to Cu by boiling with water and Zn, Sn, or Fe (Berthemot, *J. Ph.* 15, 445). When Cu_2I_2 is dissolved in NH_3Aq by heating in an open vessel, colourless crystals of $Cu_2I_2.4NH_3$ separate on cooling, and the mother liquor on addition of alcohol deposits a dark-blue compound $CuI_2.4NH_3.H_2O$ (Rammelsberg, *P.* 48, 162; *v.* also Berthemot, *J. Ph.* 15, 445; and Saglier, *C. R.* 102, 1552). Cu_2I_2 dissolves in alcoholic I; when this liquid is heated to 30°, and mixed with alcoholic NH_3 at 30°, crystals separate in a few hours having the composition $CuI_2.4NH_3.I_2$ (Jörgensen, *J. pr.* [2] 2, 353).

Combinations.—1. With *ammonia* to form $Cu_2I_2.4NH_3$ (Rammelsberg, *P.* 48, 162). Obtained by passing NH_3 over Cu_2I_2; white, lustrous crystals; decomposed by heat to Cu_2I_2 and NH_3. The same compound is formed by mixing KIAq with an ammoniacal solution of a cuprous salt in absence of air; as thus obtained the compound cannot be dried without losing NH_3 (Levol, *N. J. P.* 4, 328).—2. With *ammonium iodide*; the compound $Cu_2I_2.2NH_4I.H_2O$ is obtained, as white needles, by dissolving 100 gs. NH_4I in 1,000 gs. water, adding 10–15 gs. $Cu(OH)_2$, heating until all is dissolved, boiling with a large excess of Cu until the liquid is colourless, and allowing to cool. The mother liquor in air deposits black crystals of $Cu_2I_2.2NH_4I.2NH_3.4H_2O$. These crystals are very unstable (Saglier, *C. R.* 104, 1440).—3. With *ammonia and cupric iodide*; when 100 gs. of an ammoniacal solution of CuO, containing 7–8 p.c. CuO, is mixed with an equal mass of 10 p.c. alcoholic I solution, warmed until the pp. of NI_3 dissolves, heated in the water bath for an hour, and allowed to cool, brilliant green crystals are deposited of the composition $Cu_3I_4.4NH_3$, probably $= Cu_2I_2.CuI_2.4NH_3$ (Saglier, *C. R.* 102, 1552).—4. With *silver iodide* to form a series of bodies resembling alloys; $Cu_2I_2.xAgI$, x varying from 1 to 12; for physical constants of these bodies *v.* Rodwell, *Pr.* 33, 143; Bellati a. Romanese, *Pr.* 34, 104. According to Guyard (*Bl.* [2] 41, 12) a double iodide of Cu and N is produced when an alkaline di-iodide is added to an ammoniacal Cu solution.

II. CUPRIC IODIDE. Cupric iodide, CuI_2, has not been isolated. A solution of Cu_2I_2 in alcoholic I is not ppd. by water, but on heating and adding alcoholic KI, Cu_2I_2 is reppd. along with KI_3, the solution may perhaps contain a periodide of Cu (Jörgensen, *J. pr.* [2] 2, 347). Cu_2I_2 in presence of I dissolves in much water; this solution probably contains CuI_2 (Traube, *B.* 17, 1064). Carnegie (*priv. comm.*) has obtained aqueous solutions of cupric iodide containing c. ·3 g. CuI_2 in 100 c.c., by digesting Cu_2I_2 with I in water at 80° for a few minutes, cooling, shaking *for a short time* with Cu foil or CS_2 to remove excess of I. Solution of CuI_2 containing c. ·9 g. CuI_2 with excess of I is very easily decomposed, almost anything that removes the I at the same time decomposes the CuI_2 to CuI and I, *e.g.* starch or Ag leaf; the solution partially decomposes when boiled out of contact with air, also when a current of air, N, or other indifferent gas, is passed through it, and even when kept *in vacuo* at the ordinary temperature. Solutions of CuI_2 are also obtained by digesting CuO_2H_2, or $CuCO_3$, with fairly conc. HIAq saturated with I, and filtering from excess of CuO_2H_2, or $CuCO_3$. Potassium iodide withdraws I from solutions of CuI_2, ppg. CuI; when KI interacts with a cupric salt in molecular proportions, CuI_2 is almost certainly produced, but as the change is not complete the residual KI interacts with the CuI_2 in solution to produce CuI and KI.xI. Thomsen gives $[Cu,I^2,Aq] = 10{,}410$ (*Th.* 3, 320).

Various compounds are known, one constituent of each of which is probably CuI_2. The formation of the compounds $CuI_2.4NH_3.H_2O$, and $CuI_2.Cu_2I_2.4NH_3$ has been described (*v.* CUPROUS IODIDE, *Reactions*, also *Combinations*, No. 3). The compound $CuI_2.4NH_3.I_4$ was obtained by Jörgensen (*J. pr.* [2] 2, 353) as blue crystals, by mixing solutions of I in KI and Cu-NH_4 nitrate, at 50°, and filtering hot into water at 50° (*v.* also Saglier, *C. R.* 102, 1552). Saglier (*C. R.* 104, 1440) describes the compounds $CuI_2.2NH_4I.2NH_3.2H_2O$, and $CuI_2.4NH_3.H_2O$, produced by boiling NH_4IAq with $Cu(OH)_2$; he also describes a compound with $(NH_4)I_2$, viz. $CuI_2.2NH_4I_2.2NH_3.6H_2O$, obtained by dissolving $Cu(OH)_2$ in hot NH_4I_2Aq.

Carnegie (*priv. comm.*) has obtained the compound $CuO.2CuI_2.4H_2O$ by partially immersing slips of Cu in BaI_2Aq; black crystals slowly form on the sides of the vessel; they are easily decomposed by washing with water; they may be washed with alcohol and dried over $CaCl_2$.

Copper, Nitride of. Cu_3N. When finely divided CuO, ppd. from hot $CuSO_4Aq$ by KOH, is heated in a tube to 250° and dry NH_3 is passed over it, greenish-black copper nitride is formed; if the solid is powdered from time to time and the passage of NH_3 is continued, the whole of the CuO may be changed to nitride. Copper nitride decomposes by heating to about 300°, giving Cu and N; in Cl it gives $CuCl_2$ and N; in HClAq, $CuCl_2$, and NH_4Cl are formed; it is oxidised rapidly by HNO_3Aq, and decomposed to Cu and N by H_2SO_4Aq (Schrötter, *A.* 37, 136; *v.* also Warren, *C. N.* 55, 155). By heating to bright redness discs of Cu and Pt placed 3–4 mm. apart in an atmosphere of N, Blondlot got indications of the formation of a compound of Cu and N; but he did not isolate the compound (*C. R.* 102, 210). According to Schrötter (*l.c.*) Cu and N do not directly combine.

Copper, Oxides of. Copper forms four oxides; Cu_4O, Cu_2O, CuO, and CuO_2. There are indications of the existence of other oxides, but none has been certainly isolated. The best-studied are Cu_2O and CuO; both are basic, and each forms a series of corresponding salts, those corresponding to CuO being the more stable. The oxide Cu_4O reacts with acids to form Cu and a salt, in some cases a cuprous, and in other cases a cupric, salt. The oxide CuO_2 reacts with acids as a basic peroxide, forming cupric salts and oxygen. Any oxide other than CuO is changed into CuO by heating in air or oxygen. By adding solution of bleaching powder to $Cu2NO_3Aq$, a pp. is obtained which soon decomposes with evolution of O; this pp. is possibly a salt the acidic radicle of which is composed of Cu and O (*v.* p. 260). No oxide of Cu has been gasified, hence the formulæ given are not necessarily molecular.

I. Copper suboxide Cu_4O. (*Quadroxide of copper*) (Rose, *P.* 120, 1). An olive-green powder; stable under water in absence of O, but rapidly oxidised in air to Cu_2O and then to CuO; decomposed by dilute HClAq to Cu_2Cl_2 and Cu, and by dilute H_2SO_4Aq to $CuSO_4$ and Cu; insoluble in NH_3Aq, and in a mixture of NH_3Aq and $(NH_4)_2CO_3Aq$. Prepared by reaction between $CuSO_4Aq$ and $SnCl_2$ in presence of KOH; $Cu(OH)_2$ is first precipitated and then reduced with simultaneous formation of K stannate: $4Cu(OH)_2 + 12KOHAq + 3SnCl_2Aq$ $= Cu_4O + 6KClAq + 3K_2SnO_3Aq + 10H_2O$. To prepare this oxide, Rose directs to make 300 c.c. $CuSO_4Aq$ containing 10 g. Cu; to add this to 1,000 c.c. of a solution of 50 g. $SnCl_2$ in KOHAq, and to shake in a well-closed vessel which is completely filled with the liquid, keeping cool by water; to filter after twenty-four hours in an atmosphere of H, and wash the pp. with water containing KOH, then with water, then with very dilute NH_3Aq, and finally with water. It is difficult to obtain Cu_4O free from the other oxides. (For precautions *v.* Rose, *l.c.*)

II. Cuprous oxide Cu_2O. (*Hemi-oxide of copper. Protoxide of copper. Red oxide of copper.*) S.G. 4° 5·749 (native), 5·345–5·375 (artificial). H.F. $[Cu^2,O] = 40,810$ (*Th.* 3, 320). Occurs native as *Cuprite*, in lustrous, red, octahedra.

Formation.—1. By heating Cu in air; the outer film thus formed is CuO, beneath this is a film of Cu_2O. Finely divided Cu (obtained by reducing CuO in H at a moderate temperature) oxidises in air to Cu_2O (Berzelius, *A.* 61, 1; *v.* also Mitscherlich, *J. pr.* 19, 450; and Marchand, *J. pr.* 20, 505).—2. By heating Cu turnings with CuO (Berzelius), or with dehydrated $CuSO_4$ (Ullgren, *P.* 55, 527), or with $CuSO_4$ and Na_2CO_3 (Malaguti, *J. pr.* 2, 167).—3. By heating Cu_2Cl_2 with Na_2CO_3 (Wöhler a. Liebig, *P.* 21, 581).—4. By the reaction of Cu with $Cu2NO_3$ and a little CuO, in absence of air (Becquerel, *A. Ch.* 41, 223).—5. By the prolonged action of NH_3Aq on a mixture of $CuSO_4Aq$ and $FeSO_4Aq$ in presence of $Fe_2(OH)_6$ (Wibel, *Reduction von Kupferoxydsalzen* [Hamburg, 1864], 2).

Preparation.—1. 5 pts. Cu_2Cl_2 are heated with 3 pts. dehydrated Na_2CO_3, the resultant mass is washed with water (W. a. L., *P.* 21, 581).—2. A mixture of 1 pt. $CuSO_4.5H_2O$, 1½ pts. cream of tartar, 2 pts. grape sugar, in 12 pts. water, is heated in a basin; 1½ pts. NaOH are added, and the whole is boiled until the supernatant liquid is colourless; the pp. is washed with water, then with alcohol, and dried (Böttger, *D. P. J.* 171, 77).—3. An intimate mixture of equal parts CuO and $(NH_4)_2CO_3$ is heated over a Bunsen-burner till the smell of NH_3 is no longer apparent (Schiff, *W. J.* 1864. 274).

Properties.—A carmine-red crystalline powder. Melts at full red heat and oxidises to CuO. Soluble in NH_3Aq, forming a colourless liquid which becomes blue in the air, and reacts as a strong reducing agent.

Reactions.—1. *Hydrochloric acid* forms Cu_2Cl_2, soluble in excess of the acid $[Cu^2O,2HClAq] = 14,660$ (*Th.* 3, 320).—2. *Dilute acids, e.g.* H_2SO_4Aq, HNO_3Aq, H_3PO_4Aq, $H.H_3C_2O_2Aq$, produce Cu and cupric salts.—3. *Conc. nitric acid* forms $Cu2NO_3$.—4. *Bromine water* forms $CuBr_2$ and CuO.—5. Reduced to Cu by *hydrogen, potassium*, or *carbon*.—6. *Sulphur* forms Cu_2S.—7. Many *metallic chlorides in solution, e.g.* $MgCl_2Aq$, $ZnCl_2Aq$, form soluble double salts and also ppt. hydrated oxides of the metals.—8. *Ferric chloride* solution produces Fe_2O_3, Cu, and Cu_2Cl_2.—9. From neutral *silver solution* Cu_2O ppts. a mixture of Ag and a basic cupric salt.

Hydrated cuprous oxide ?$4Cu_2O.H_2O$. Produced, as a yellowish powder, by adding an alkali or alkaline carbonate to the solution of a cuprous salt (Fremy, *A. Ch.* [3] 23, 391). Also formed by heating to boiling moist $Cu(OH)_2$ with milk sugar and some Na_2CO_3Aq. According to Mitscherlich (*J. pr.* 19, 450) the hydrate loses its water at 360°. Oxidises in air to $Cu(OH)_2$ (*v.* also *Gm.-K.* [6th ed.] 3, 595; Millon a. Commaille, *C. R.* 57, 145; Field, *C. J.* [2] 1, 28; P. de Saint-Gilles, *A. Ch.* [3] 42, 36). Dissolves in dilute acids to form cuprous salts, very few of which have been isolated.

III. Cupric oxide CuO. (*Black oxide of copper. Copper oxide.*) S.G. 6·1 to 6·4 (Boullay, *A. Ch.* [2] 43, 266; Playfair a. Joule, *C. S. Mem.* 3, 57). H.F. $[Cu,O] = 37,160$ (*Th.* 3, 320). Occurs native in North America as *Melakonite.* Crystallises in monoclinic forms; $a:b:c = 1·49:1:1·36$ (Maskelyne, *B. A.* 1865).

Formation.—1. By heating Cu in air or O, removing the scales which form, and strongly heating in air.—2. By heating $Cu2NO_3$, $Cu(OH)_2$, $CuCO_3$, or very strongly heating $CuSO_4$.

Preparation.—1. Pure Cu, prepared by electrolysis, is dissolved in HNO_3Aq, to one-half of the solution NH_3Aq is added until the pp. which forms has just dissolved, the other half of the liquid is then added, the whole is evaporated to dryness, and the Cu nitrate thus obtained is strongly heated; the oxide thus formed is well washed, and again heated in a Pt dish (Reischauer, *J.* 1863. 274; Erdmann a. Marchand, *J. pr.* 31, 389). The oxide must not be too strongly heated else it partially fuses and contains Cu_2O; according to Thudichum a. Kingzett (*C. J.* [2] 15, 363) the oxide should be heated *in vacuo* to remove traces of CO_2.—2. A solution of equivalent masses of $CuSO_4.5H_2O$ and Na_2CO_3 is evaporated to dryness and the residue is heated strongly in a crucible and then well washed; moist air is then passed over the heated oxide to remove traces of chlorides (Stanford, *C. N.* 7, 81; Erlenmeyer, *Z.* 1863. 157). The oxide as thus prepared is specially adapted for use in organic analysis.—3. The oxide is obtained in crystals by dropping Cu_2Cl_2 in small successive quantities into a red hot Pt crucible (Schulze, *J. pr.* [2] 21, 413); Becquerel (*A. Ch.* 51, 122) obtained crystals of CuO by heating to dull redness

5 grams amorphous CuO with 2–3 grams pure KOH, washing with water, and separating the crystals by shaking.

Properties.—Brown-black amorphous powder; or metal-like, lustrous, monoclinic crystals. Hygroscopic (*v.* Rentzsch, *J. pr.* [2] 21, 413). Slightly volatile in a porcelain-oven (Elsner, *J.* 1866. 35). Said to lose O when strongly heated giving $CuO.2Cu_2O$ (Favre a. Maumené, *C. R.* 18, 658). According to Reischauer (*J.* 1859. 216) Cu_2O is formed by very strongly heating CuO; this is confirmed by Debray and Joannis (*C. R.* 99, 583) provided the heating is conducted *in vacuo*. According to Joannis (*C. R.* 102, 1157) CuO prepared at a high temperature develops less heat when dissolved in HClAq than specimens prepared at a low temperature. CuO is a basic oxide reacting with acids to form cupric salts CuX_2 [$X = NO_3, \frac{SO_4}{2}$ &c.]; it dissolves in much KOHAq, and perhaps forms salts in which CuO acts as an acidic radicle.

Reactions.—1. Easily reduced to Cu by heating in *hydrogen* or *carbon monoxide*, or with *carbon* or *carbon compounds* [hence its use in organic analysis] (for temperatures at which reduction in H and CO begins *v.* Wright a. Luff, *C. J.* 33, 1).—2. Heated with *copper* forms Cu_2O.—3. Heated with *phosphorus*, phosphide and phosphate of Cu are formed.—4. Heated with *sulphuretted hydrogen*, or with *sulphur in a stream of hydrogen*, Cu_2S is formed (Rose, *P.* 110, 120).—5. Heated with *sulphur* alone gives Cu_2S and SO_2 if S is in excess, or Cu_2O and $CuSO_4$ if CuO is in excess (Jordan, *J. pr.* 28, 222).—6. Heated with *salammoniac* Cu_2Cl_2 and a little $CuCl_2$ are formed.—7. Heating with *ferric chloride* produces Fe_2O_3 with $CuCl_2$ and Cu_2Cl_2 (Hunt, *C. R.* 69, 1357).—8. Reacts with *zinc-chloride* solution to produce a green powder $Zn_3Cu_5Cl_4.6H_2O$ (André, *C. R.* 106, 854).—9. Soluble in *ammonia*, also in *molten potash*.—10. *Acids* dissolve CuO with formation of cupric salts: Thomsen gives the following thermal data ($M = CuO$); $[M,2HClAq] = 15{,}270$; $[M,H^2SO^4Aq] = 18{,}800$; $[M,2HNO^3Aq] = 15{,}250$; $[M,2HClO^4Aq] = 15{,}910$; $[M,2C^2H^4O^2Aq] = 13{,}180$; $[M,SO^3] = 42{,}170$; $[Cu,O,H^2SO^4Aq] = 55{,}960$; $[Cu,O,2HNO^3Aq] = 52{,}410$.

Combinations.—1. With *water* to form $CuO.H_2O$, produced indirectly, *v. infra.*—2. With *water and ammonia* to form $xCuO.yNH_3.zH_2O$. CuO dissolves in NH_3Aq in presence of air, especially if a small quantity of an NH_4 salt is present (Berzelius). Kane (*A. Ch.* [2] 72, 283) obtained the compound $3CuO.4NH_3.6H_2O$ by adding NH_3Aq to $CuCl_2Aq$. Malaguti a. Sargeau (*A. Ch.* [3] 9, 438) obtained $CuO.4NH_3.4H_2O$ by treating with NH_3 the mother-liquor from the preparation of $Cu\text{-}NH_4$ chromate. A solution of CuO in NH_3Aq dissolves cellulose; the solution is conveniently prepared either by digesting Cu spirals with NH_3Aq in air, or by ppg. $CuSO_4Aq$ by the calculated quantity of NaOHAq, washing the pp. of $Cu(OH)_2$ and dissolving it in NH_3Aq (Schweizer, *J. pr.* 72, 109). Ammoniacal solutions of CuO are reduced with ppn. of Cu, by P, Zn, Co, &c.—4. With a few *metallic oxides* to form compounds of the type $CuO.xM_2O_3$; *e.g.* $CuO.Fe_2O_3$, formed by heating together the two oxides (List, *B.* 11, 1515), or by the reaction of CuO with Fe_2Cl_6Aq, or by ppg. by KOHAq a solution of equivalent masses of a Cu and a ferric salt. The compound $3CuO.Mn_2O_3$ is obtained by adding NaOH to an ammoniacal solution of CuO, and then $MnCl_2Aq$ drop by drop with constant stirring (Schneider, *Am.* 9, 269). The compound $CuO.Cr_2O_3$ is described by Persoz (*A. Ch.* [3] 25, 283).

HYDRATED CUPRIC OXIDE or COPPER HYDROXIDE $CuO.H_2O = Cu(OH)_2$.

Preparation.—Obtained by adding dilute NaOHAq or KOHAq in slight excess to $CuSO_4Aq$; or preferably by adding $CuSO_4Aq$ to NaOHAq, keeping the latter in excess (Oglialoro, *J.* 1876. 217); washing very many times, and drying at a low temperature. Böttger (*J. pr.* 73, 491) recommends to drop NH_3Aq into boiling $CuSO_4Aq$ until the pp., which at first is greenish, becomes blue, to wash this pp. thoroughly, and then to add fairly conc. NaOHAq, keeping the temperature about 20°–40° (*v.* also Löwe, *D. P. J.* 149, 270; Péligot, *C. R.* 53, 209).

Properties.—A blue solid, sometimes crystalline, very easily dehydrated. Heated in presence of water it turns black, the change occurring more readily if KOH or NaOH is present; the black compound is $3CuO.H_2O$ according to Harms (*J.* 1857. 246), $6CuO.H_2O$ according to Rose (*P.* 84, 480). When heated to 100° it loses water, but it is not fully dehydrated even at 200°–300° according to Rose (*l.c.*; *cf.* Schaffner, *A.* 51, 168). The hydrate is soluble in acids, also in NH_3Aq, and in solutions of NH_4 salts; also in $Na_2S_2O_8Aq$ (Field, *C. J.* [2] 1, 28).

Reactions.—1. With *ferrous hydroxide* produces $Fe_2O_6H_6$ and $Cu_2O.xH_2O$ (Levol, *A. Ch.* 65, 320).—2. With *ferrous sulphate* solution produces $Cu_2O.xH_2O$ and basic ferric sulphate (Braun, *J.* 1867. 301).—3. Dissolves in *acids* to form cupric salts.—4. Dissolves in 4 to 6 parts *molten potash*; on adding water CuO is formed, but some of the Cu remains in solution, and on adding a large excess of KOHAq all dissolves.—5. Dissolves in *large excess* of *potash solution* to a blue liquid; according to Chodnew (*J. pr.* 28, 217) this liquid remains blue on boiling or on adding much water, but on standing in air for a long time a part of the Cu in solution is ppd. as $CuO.H_2O$; addition of HClAq to the blue liquid until nearly neutral ppts. $Cu(OH)_2$, but a little Cu remains in solution. Chodnew (*l.c.*) also states that addition of a large excess of KOHAq to $CuSO_4Aq$ or $Cu(NO_3)_2Aq$ causes some of the $Cu(OH)_2$ to dissolve; the solutions must be cold and dilute; the whole of the Cu is not ppd. on boiling. The hydrate dissolves in NaOHAq (70 p.c.), and gives a blue pp. on long standing, containing CuO and Na_2O according to Löw (*Fr.* 9, 463).

IV. COPPER PEROXIDE.—The oxide CuO_2 has not been obtained, but a hydrate $CuO_2.H_2O$ is known. This hydrate is prepared (1) by digesting finely-divided CuO, or $Cu(OH)_2$, with H_2O_2Aq for several days at 0° (Thénard; Krüss, *B.* 17, 2593); (2) by shaking very dilute $CuSO_4Aq$ with excess of $MnO_2.xH_2O$ or PbO_2, keeping cold (Schmid, *J. pr.* 98, 136); (3) by adding H_2O_2Aq to a solution of $Cu\text{-}NH_4$ sulphate (Weltzien, *A.* 140, 207). $CuO_2.H_2O$ is very easily decomposed with evolution of O; decomposition of the moist hydrate in presence of water begins at 6° (Krüss, *l.c.*). When quickly washed with *cold* water, pressed between paper, and then dried *in vacuo*, it is obtained pure. This hydrate forms an olive-green powder; it reacts with acids to give cupric salts and H_2O_2; dilute HClAq is said to produce a little O.

Oxides of copper other than Cu_4O, Cu_2O, CuO, and CuO_2. Different chemists have asserted the existence of oxides of the form xCuO.$y$$Cu_2O$ intermediate between CuO and CuO_2, obtained either by strongly heating CuO, or by the action of hypochlorites on cupric salts in solution (*v.* Krüger, *P.* 62, 445; Crum, *A.* 55, 218; Fremy, *A. Ch.* [3] 12, 457; Krüss, *B.* 17, 2593). But according to Osborne (*Am. S.* [3] 32, 333) these bodies are all mixtures of CuO and Cu_2O; this result is confirmed by the experiments of Debray and Joannis on the dissociation of these mixtures (*C. R.* 99, 583), and by the thermal measurements made by Joannis (*C. R.* 100, 999).

Copper, oxybromide of, *v.* COPPER, OXYHALOID COMPOUNDS OF.

Copper, oxychlorides of, *v.* COPPER, OXYHALOID COMPOUNDS OF.

Copper, oxyfluoride of, *v.* COPPER, OXYHALOID COMPOUNDS OF.

Copper, oxyhaloid compounds of.—Several oxychlorides of the form $Cu_xCl_yO_z$ are known; an oxyfluoride $CuF_2.Cu(OH)_2$, and an oxyiodide $2CuI_2.CuO.4H_2O$, are also known; an oxybromide probably exists, but it has not been isolated.

COPPER OXYBROMIDE.—When a little NH_3Aq is added to $CuBr_2$Aq, a pale-green pp. is obtained, which becomes grey on heating; both of these bodies are oxybromides according to Löwig (*P.* 14, 485).

COPPER OXYCHLORIDES.—Various compounds of CuO with $CuCl_2$ are obtained by digesting $CuCl_2$ with $Cu(OH)_2$, also by the incomplete ppn. of $CuCl_2$ by alkalis, and also by the action of O on moist $CuCl_2$. The following are the chief oxychlorides:—

I. $CuCl_2.2CuO.4H_2O$; blue-green pp. by adding to $CuCl_2$ enough KOH to decompose $\frac{3}{5}$ of the $CuCl_2$; or by diluting $CuCl_2$Aq until the liquid is blue (Gladstone, *C. J.* 8, 211). This oxychloride loses $3H_2O$ at 140°, leaving a chocolate-coloured monohydrate (Kane, *A. Ch.* 72, 277).

II. $2(CuCl_2.3CuO).7H_2O$; green pp. by adding excess of $NaC_2H_3O_2$Aq to boiling $CuCl_2$Aq, or by the action of NaClAq on $Cu(C_2H_3O_2)_2$ (Casselmann, *Fr.* 4, 24). Also obtained by adding NH_3Aq, insufficient for complete decomposition, to a mixture of $CuSO_4$Aq with excess of NaCl (Reindel, *J. pr.* 106, 378).

III. $CuCl_2.3CuO.4H_2O$; occurs native as *Atacamite*; used in the arts as *Brunswick green.* Prepared by the action of air on copper plates covered with HClAq or NH_4ClAq; or by digesting in air a mixture of NaCl, Cu turnings, and $CuSO_4.5H_2O$ with enough water to form a thick magma, or by exposing moist Cu_2Cl_2 to the air (Vogel, *D. P. J.* 136, 238; *v.* also Field, *P. M.* [4] 24, 128; Debray, *Bl.* [2] 7, 104).

COPPER OXYFLUORIDE $CuF_2.Cu(OH)_2$ [= CuF.OH] (Balbiano, *G.* 14, 74). A greenish-white solid obtained by adding to HFAq, CuO or $CuCO_3$ in quantity not sufficient to saturate the acid; or by mixing $CuSO_4$Aq and KFAq.

COPPER OXYIODIDE $2CuI_2.CuO.4H_2O$; prepared by the action of Cu on BaI_2Aq in presence of air (*v. suprà*, CUPRIC IODIDE).

Copper, oxysulphides of, xCuS.yCuO. When Na_2SAq is dropped into an ammoniacal solution of $CuSO_4$ at 70°-80° till the blue colour disappears, a pp. of 5CuS.CuO is formed; at higher temperatures the pp. contains more CuO, and at ordinary temperatures CuS is the product (Pelouze, *A. Ch.* [3] 17, 393). According to Maumené (*A. Ch.* [3] 18, 311) various oxysulphides are formed during the action of conc. H_2SO_4 with Cu, but this is negatived by the experiments of Pickering (*C. J.* [2] 18, 112).

Copper, phosphides of.—Two phosphides of copper are known, Cu_3P_2 and Cu_6P_2; another, Cu_2P_2, probably exists. The molecular weight of none of these compounds is known with certainty. Cu and P may be melted together in all proportions.

I. TRI-COPPER PHOSPHIDE Cu_3P_2. Obtained by passing PH_3 over warm $CuCl_2$, or by passing PH_3 into $CuSO_4$Aq (H. Rose, *P.* 14, 188; 24, 328). According to Böttger (*J.* 1857. 107) the pp. produced by boiling P with $CuSO_4$Aq, and washing with $K_2Cr_2O_7$Aq acidulated with H_2SO_4 (to remove basic Cu phosphate), has the composition Cu_3P_2. Prepared by the reaction of PH_3 with $CuCl_2$, the phosphide is a black solid, insol. HClAq, and loses half its P when strongly heated in H. Prepared by passing PH_3 into $CuSO_4$Aq, the phosphide is sol. HClAq with evolution of inflammable PH_3. Prepared by Bottger's method the phosphide is an easily oxidised powder, slowly dissolved by HClAq with evolution of non-inflammable PH_3 (*v.* also Sidot, *C. R.* 84, 1454).

II. HEXACOPPER PHOSPHIDE Cu_6P_2. Obtained by leading PH_3 over heated Cu_2Cl_2 or Cu_2S (H. Rose, *P.* 6, 209; 24, 328); by strongly heating Cu_3P_2 in H (Rose, *l.c.*); by passing P vapour over Cu heated to dull redness (Abel, *C. J.* [2] 3, 249). Grey-black solid, sol. HNO_3Aq, insol. HClAq.

A DI-COPPER PHOSPHIDE, Cu_2P_2, is described as a grey powder obtained by heating $CuHPO_4$ in a stream of H (H. Rose, *P.* 14, 188; 24, 328). Also produced by heating P with Cu turnings, and then carefully heating the product with amorphous P (Berzelius; but *cf.* Abel, *C. J.* [2] 3, 249). A phosphide, having the composition Cu_2P_2, was obtained by Cross a. Higgins (*C. J.* 35, 424) by heating Cu_2Cl_2Aq with amorphous P to 160° for many hours.

Copper, salts of. Compounds obtained by replacing H of acids by Cu. Copper forms two classes of salts, the *cuprous* Cu_2X_2 [X = Cl, Br, I, SCN, $\frac{SO_3}{2}$, &c.], and the *cupric* CuX_2 [X = Cl, NO_3, $\frac{SO_4}{2}$, $\frac{CO_3}{2}$, &c.]. Few cuprous salts except those derived from haloid acids are known; a few double salts of this class have been prepared, *e.g.* $Cu_2SO_4.(NH_4)_2SO_4$, and some *cupro-cupric* salts are known, *e.g.* $Cu_2SO_3.CuSO_3.5H_2O$. The cuprous salts are generally insol. water, while the normal cupric salts as a class dissolve in water. The cuprous salts are less stable than the cupric; but cuprous iodide is so much more stable than cupric iodide, that the latter has not been isolated, reactions which might be expected to yield CuI_2

(*e.g.* $KIAq + CuSO_4Aq$) produce Cu_2I_2 and iodine. Many basic cupric salts are known. The cuprous salts are not generally obtained by reacting on Cu_2O with acids, but by reduction of cupric salts (*v. e.g.* CUPROUS CHLORIDE). Cupric salts are usually obtained by reactions between acids and CuO or $CuCO_3$. A great many cupric salts have been prepared (*v.* CARBONATES, NITRATES, SULPHATES, &c.); the following are the chief salts of this class:—*bromate*, *carbonates*, *chlorate* (and salts of other chlorine oxyacids), *iodate* and *periodate*, *molybdates*, *nitrates* and *nitrites*, *phosphate* (and salts of other phosphorus oxyacids), *selenates* and *selenite*, *silicates*, *sulphates* and *sulphites*, *tungstates*, *uranates*, *vanadates*.

Copper, selenides of. I. CUPROUS SELENIDE Cu_2Se. A steel-grey mass, obtained by heating Cu turnings with Se. Occurs native as *Berzelianite*. II. CUPRIC SELENIDE $CuSe$. A greenish-black solid, obtained by passing Se vapour over copper plates (Little, *A.* 112, 211); S.G. 6·66. Also formed by passing H_2Se into a solution of a cupric salt (Berzelius).

Copper, silicide of. No definite compound has been isolated. Bodies more or less resembling alloys of Cu and Si are obtained by heating K_2SiF_6 with Na and Cu (*v.* Deville a. Caron, *C. R.* 45, 163; Winkler, *J. pr.* 91, 193).

Copper, silicofluoride of, $CuSiF_6.6H_2O$. Blue crystals, obtained by dissolving CuO in H_2SiF_6Aq; deliquescent; heated to 60° gives $CuSiF_6.4H_2O$ (Berzelius; Stolba, *J. pr.* 102, 7). Decomposed at 130°–140° giving $CuF.OH$, SiF_4, and HF; absorbs NH_3 giving $CuF.OH.2NH_3$, NH_4F, and SiO_2 (Balbiano, *G.* 14, 74).

Copper, sulphides of. Two sulphides of copper are known, Cu_2S and CuS. As neither has been gasified the molecular formulæ are not known with certainty; Pickering (*C. J.* 39, 401) says that CuS heated in H at 260° gives Cu_2S, and at c. 650° it yields Cu; because of this reaction he thinks that the formula of cupric sulphide ought to be Cu_2S_2 and not CuS. *Cuprous sulphide*, Cu_2S, is the more stable of the two sulphides; both are distinctly basic, forming the basic radicles of various sulpho-salts; but CuS also combines with Na_2S &c., forming compounds in which CuS acts as the negative radicle (*v.* CUPROUS, and CUPRIC, SULPHIDE; *Combinations*). Compounds are also known which probably contain the radicle CuS_3 (*v.* p. 262).

I. CUPROUS SULPHIDE Cu_2S. Occurs native as *Copper-glance*; S.G. 5·97 (Karsten, *S.* 65, 320, 394). Crystallises in rhombic forms *a*:*b*:*c* = ·582:1:·973; and also in regular octahedra; isomorphous in both forms with Ag_2S. Forms compounds with some less positive sulphides (*v. Combinations*).

Formation.—1. By heating a mixture of 4 parts finely divided Cu with 1 part S (Winkelblech, *A.* 21, 34). Spirals of Cu burn in S vapour to Cu_2S. Cu_2S is also formed by repeatedly and strongly pressing together a mixture of Cu and S (Spring, *B.* 16, 999).—2. By the action of NH_4SHAq on Cu (Heumann, *B.* 6, 748).—3. By heating $CuSO_4$ with carbon.

Preparation.—1. By heating electrolytically deposited copper with conc. H_2SO_4 for a short time at c. 124° (Pickering, *C. J.* 39, 402).—2. By heating pure CuS in a stream of H to c. 265° so long as H_2S is evolved (P., *l.c.*).—3. By passing H_2S into solution of a Cu salt in presence of $NaHCO_3$ at 200° (de Senarmont, *A. Ch.* [3] 32, 116).—4. By heating $CuSO_4$, or other Cu salt, in dry H_2S and then in H (Carnot, *Bl.* [2] 32, 163).

Properties and Reactions.—(S.G. *v. supra.*) Greyish-blue solid, fusible at moderate temperature.—1. Generally said to be unchanged when heated in *hydrogen*, but according to Pickering it is reduced to Cu by heating in H stream at c. 650° (*C. J.* 39, 404).—2. Reduced to Cu by heating to white heat in *water vapour* (Regnault, *A. Ch.* 62, 387).—3. *Chlorine* slowly acts on hot Cu_2S.—4. Heated in *air* gives $CuSO_4$ and CuO.—5. Heated with *cupric oxide* forms SO_2 and Cu or Cu_2O.—6. Heated with *litharge*, SO_2, a little Cu_2O, PbO, and Pb are formed.—7. *Phosphoretted hydrogen* forms Cu phosphide.—8. *Alkali carbonate* does not react with Cu_2S when the two are heated together, but in presence of carbon or caustic alkali a part of the Cu_2S is reduced to Cu.—9. Heated with *nitre*, K_2SO_4 and Cu are formed.—10. *Silver nitrate* reacts in accordance with the equation $Cu_2S + 4AgNO_3 = 2Cu(NO_3)_2 + Ag_2S + 2Ag$ (Heumann, *B.* 6, 751; 8, 534; Schneider, *P.* 152, 471; 154, 295).—11. Boiling conc. *hydrochloric acid* slowly forms Cu_2Cl_2; *cold nitric acid* forms CuS and $Cu(NO_3)_2$; *hot nitric acid* forms $Cu(NO_3)_2$ and separates S.—12. Heated in *carbon dioxide* to about 250°–300° Cu is formed (Pickering, *C. J.* 39, 405).

Combinations.—1. With *non-metallic sulphides* (i.) $Cu_2S.P_2S_3$, and $2Cu_2S.P_2S$; produced, the former by adding P_2S to ammoniacal Cu_2Cl_2Aq, the latter by heating the first to redness in a retort (Berzelius, *P.* 7, 29). (ii.) $2Cu_2S.P_2S_3$; the pp. from ammoniacal Cu_2Cl_2Aq by alkaline polysulphides is heated with P_2S (Berzelius). (iii.) $3Cu_2S.2As_2S_3$, occurs native as *Binnite*; $3Cu_2S.As_2S_5$ occurs native as *Enargite*. (iv.) $Cu_2S.Sb_2S_3$ occurs native as *Copper-antimony glance*; $3Cu_2S.Sb_2S_5$ is formed by heating $2Cu_2S.CuS.Sb_2S_5$ which is produced by precipitating $CuSO_4Aq$ by Na_3SbS_4.—2. With *metallic sulphides*. $Cu_2S.Fe_2S_3$, $3Cu_2S.Fe_2S_3$, and $Cu_2S.2FeS.Fe_2S_3$ occur as minerals.—3. *With non-metallic and metallic sulphides.* (i.) $4(Cu_2Fe)S.As_2S_3$ = *Tennantite*; $3Cu_2S.3FeS.As_2S_5$ = *Epigenite*. (ii.) $Cu_2S.2PbS.Sb_2S_3$ = *Bournonite*.

II. CUPRIC SULPHIDE CuS (or Cu_2S_2, *v.* beginning of COPPER, SULPHIDES OF) occurs native as *Covellite*; S.G. 4·59 to 4·64 (Karsten, *S.* 65, 320, 394). A green-black solid; by compressing at 6500 atmos. appears as dark-blue metal-like mass (Spring, *B.* 16, 1142). Acts as a basic sulphide, forming compounds with less positive sulphides; but also forms compounds with Na_2S &c., in which CuS forms the negative part of the salt.

Colloidal form of CuS (Spring a. De Boeck, *Bl.* [2] 48, 165). An aqueous solution of CuS is obtained by ppg. a Cu salt solution by H_2S, or preferably by NH_4HSAq, and prolonged washing by decantation with dilute H_2SO_4Aq, then dissolving in water and boiling for a few moments to expel H_2S. The aqueous solution of CuS is dark-coloured, with slight greenish fluorescence; the CuS is ppd. by addition of various salts, *e.g.* alum, Al_23SO_4, &c.

Formation.—By adding an alkaline sulphide to solution of a Cu salt; Thomsen (*B.* 11, 2048) says that the pp. formed by adding Na_2SAq to

$CuSO_4Aq$ has the composition Cu_4S_3. By passing H_2S into solution of a Cu salt.

Preparation.—1. $CuSO_4Aq$, prepared from pure electrolytic Cu, is ppd. by H_2S, and the pp. is dried at a low temperature in a current of H_2S.—2. Pure electrolytic Cu is heated with conc. H_2SO_4 to about 180° for some little time, the residue is washed, and heated for a short time in a rapid current of H at c. 160° (Pickering, *C. J.* 39, 401).—3. Pure finely-divided Cu_2S is treated with cold conc. nitric acid, the residue is thoroughly washed.—4. 2½ parts finely divided Cu (ppd. by Zn) are gently heated with 1½ part flowers of S, so that the excess of S sublimes; any residual S may be removed by washing with KOHAq.

Properties and Reactions.—1. Moist CuS readily oxidises in *air* to $CuSO_4$.—2. *Heated* to c. 330° for some hours, Cu_2S is formed (Pickering, *C. J.* 39, 406).—3. Heated in *carbon dioxide* to c. 130° Cu_2S is formed, and at c. 350° Cu is produced; heated in *hydrogen* to c. 200° reduction begins, and at c. 265° Cu_2S is formed, and at c. 620° Cu is produced (Pickering, *C. J.* 39, 403).—4. Dissolved by *nitric acid* with separation of S; hot conc. *hydrochloric acid* slowly forms Cu_2Cl_2.—5. Dissolved by *potassium cyanide solution*, also by solution of *alkali bicarbonates*. 6. Insoluble in *alkali sulphides*.—7. Not attacked by H_2SO_4Aq containing $\frac{1}{6}$ of its volume of H_2SO_4 (Hofmann, *A.* 115, 286).

Combinations.—1. The following compounds of CuS with sulphide of arsenic and antimony are described by Berzelius, obtained by reactions between Cu salts and sulpharsenates and sulphantimonates (*P.* 7, 29); $2CuS.As_2S_5$; $12CuS.As_2S_3$; $2CuS.As_2S_3$; $3CuS.Sb_2S_5$.—2. Berzelius also describes the compounds with *phosphorus sulphides*, $CuS.P_2S$; $2CuS.P_2S_5$.—3. With *sulphides of the alkali metals*. Schneider (*P.* 138, 311) obtained $K_2S.3Cu_2S.2CuS$ ($=K_2Cu_8S_6$) by heating together 1 part finely-divided Cu, 6 parts K_2CO_3, and 6 parts S; when the same proportions of Cu, Na_2CO_3, and S were used, the compound $Na_2S.Cu_2S.CuS$($=Na_2Cu_3S_3$) was produced. Schneider also describes the compounds $K_2FeCu_3S_4$ and $Na_2FeCu_3S_4$, obtained by heating Fe, S, and K_2CO_3 or Na_2CO_3.

III. COMPOUNDS OF HYPOTHETICAL COPPER TRISULPHIDE (CuS_3). When $CuSO_4Aq$ to which excess of NH_3Aq has been added is dropped into $(NH_4)_2SAq$ until a pp. forms, the liquid is filtered and allowed to stand in absence of air, a salt $Cu_2(NH_4)_2S_7$ [? $=(NH_4)_2S.2CuS_3$] is formed in red needles. This compound is decomposed on exposure to air, or by addition of warm water. A corresponding K salt was obtained by Priwoznik (*B.* 6, 1291) by the action of alkali polysulphides on Cu_2O, CuO, or Cu_2S. (For more details *v.* Priwoznik, *l.c.*; Peltzer, *A.* 128, 184; Gescher, *A.* 141, 350; 143, 375; Bloxam, *C. J.* [2] 3, 94; Vohl, *J. pr.* 102, 82; Berzelius, *P.* 7, 29).

Copper, telluride of. By boiling a solution of Cu acetate in presence of ppd. Te, Parkman (*J.* 1861. 126) obtained Cu_2Te, as a black powder. If the solution is cold and SO_2 is added, the pp. is CuTe. M. M. P. M.

COPPER-AMMONIUM COMPOUNDS. (*Cuprammonium compounds. Cupramines*). Many of the bodies which are formed by the combination of NH_3 with the haloid and other compounds of Cu may be regarded as compounds of various hypothetical radicles supposed to be derived from NH_4, N_2H_8, N_3H_{12}, &c., by replacing H_2 by Cu_2 or Cu. Thus the compounds $CuCl_2.2NH_3$ and $Cu_2Cl_2.2NH_3$ may be formulated as $N_2H_6(Cu)Cl_2$ and $N_2H_6(Cu_2)Cl_2$ respectively. From these compounds others may be derived by assuming that part of the H is substituted by NH_4; thus the compound $CuCl_2.4NH_3$ may be formulated as $N_2H_4(NH_4)_2(Cu)Cl_2$. Compounds supposed to be derived from the hypothetical radicle $N_2H_6(Cu_2)$ are sometimes called *cupro-ammonium compounds*; examples of these are *cupro-ammonium chloride* $N_2H_6(Cu_2)Cl_2$, *diammonium-cupro-ammonium iodide* $N_2H_4(NH_4)_2(Cu_2)I_2$. Compounds supposed to be derived from the hypothetical radicle $N_2H_6(Cu)$ are sometimes called *cupri-ammonium compounds*; examples of these are *cupri-ammonium chloride* $N_2H_6(Cu)Cl_2$, *diammonium-cupri-ammonium oxide* $N_2H_4(NH_4)_2(Cu)O$. It is, however, very doubtful whether anything is gained at present by this extremely hypothetical way of formulating the double compounds of NH_3 and Cu salts. M. M. P. M.

COPRINE. A name given by Niemikowicz (*M.* 7, 241) to the methylo-hydroxide of DI-METHYL-AMIDO-ACETONE (*q. v.*).

COPTINE. An alkaloid contained, together with berberine, in *Coptis trifolia* (Gross, *N. Rep. Pharm.* 23, 53; Schultz, *Ph.* [3] 14, 973; *J. Ph.* 14, 273).

CORALLIN *v.* ROSOLIC ACID and anhydride of TRI-OXY-DI-PHENYL-TOLYL-CARBINOL.

CORIAMYRTIN $C_{30}H_{36}O_{10}$. [220°]. S. 1·44 at 22°. S. (alcohol) 2 at 22°. $[\alpha]=24{\cdot}5$ at 20°. The active principle of *Coriaria myrtifolia*, a purgative and poisonous plant growing in Southern Europe (Riban, *Bl.* 1864, i, 87; 1867, i, 79), formerly used for the production of a black dye. Prisms (from alcohol). Dextrorotatory HI forms a black pp. which gives an alcoholic solution, which is turned crimson by NaOH. Baryta forms $BaC_{30}H_{46}O_{16}$(?). Br gives $C_{30}H_{34}Br_2O_{10}$, which crystallises in needles (from alcohol).

Hexa-acetyl derivative $C_{30}H_{30}Ac_6O_{10}$ 3aq [below 100°]. Transparent brittle mass.

CORIANDER OIL $C_{10}H_{17}OH$. $[\alpha]_D=-92{\cdot}55°$ at 15°. The volatile oil of Coriander seeds (Trommsdorff, *Ar. Ph.* [2] 2, 114; Kawalier, *J. pr.* 58, 226). Decomposed by distillation forming $C_{20}H_{34}O$ (165°–170°). P_2O_5 forms a terpene $C_{10}H_{16}$. On treatment with iodine it gives cymene. It forms a solid sodium derivative $C_{10}H_{17}ONa$ and various ethers. On oxidation with neutral $KMnO_4$ it gives a ketone $C_{10}H_{16}O$ (186°), S.G. ·897, which combines with $NaHSO_3$, and is converted by further oxidation into CO_2, acetic acid, and dimethyl-succinic acid. Alkaline $KMnO_4$ oxidises it to CO_2, acetic, and oxalic acids (Grosser, *B.* 14, 2485). HCl forms $C_{10}H_{17}Cl$, S.G. ·953, while HI gives $C_{10}H_{17}I$, which explodes below 100°.

CORIDINE $C_{10}H_{15}N$. (211°). S.G. ^{22} ·974. A base of the pyridine series occurring in coal tar (Thenius, *C. C.* 1862, 53). Turns litmus paper blue. Sl. sol. water, v. sol. other ordinary menstrua. The hydrochloric acid solution gives a pp. with $HgCl_2$, which melts at 28°, but may be obtained as white needles. Colours acidified pine wood yellowish red.—$B'_2H_2PtCl_6$: orange pp.

CORK *v.* CELLULOSE, vol. i. p. 721.

CORNEÏN *v.* PROTEÏDS, *Appendix C.*

CORNICULARIC ACID $C_{17}H_{14}O_3$ or Ph.C(CO_2H):CH.CO.CH_2.Ph. [115°]. Long colourless needles or tables. Formed as a by-product in the reduction of pulvic acid to di-hydro-cornicularic acid. This latter acid is also formed by reduction of cornicularic acid with zinc-dust and NaOH (Spiegel, *B.* 15, 1546; *A.* 219, 23).

Cornicular-lactone $C_{17}H_{12}O_2$ or

$$\begin{array}{l}\text{OC———O}\\ \;\;\,|\qquad\;\;\;\, |\\ \text{Ph.C:CH.C:CH.Ph.}\end{array}$$

[141°]. Yellow needles. Insol. in caustic alkalis even on boiling.

Di-hydro-cornicularic acid $C_{17}H_{16}O_3$ *i.e.* $(C_6H_5)_2C_4H_4(OH).CO_2H$. *Di-phenyl-oxy-angelic acid.* [134°]. Colourless needles. Sol. alcohol, ether, benzene, and acetic acid, sl. sol. CS_2, insol. ligroin. Prepared by reduction of pulvic acid with zinc-dust and NH_3, CO_2 being evolved. On further reduction with sodium amalgam it gives tetra-hydro-cornicularic acid. On fusion with KOH it is resolved into phenyl-succinic acid and toluene. Distillation with quick-lime gives $C_6H_5.CH_2.CH_2.CO.CH_2.C_6H_5$. Ac_2O forms a compound $C_{17}H_{14}O_2HOAc$ [99°].

Salts.—A'Ag and A'_2Pb: amorphous white pps.

Methyl ether A'Me: colourless monoclinic prisms [68°], formed by reduction of pulvic ether or from silver dihydrocornicularate and EtI.

Lactone $C_{17}H_{14}O_2$. [117°]. Colourless needles. Sol. ether, benzene, acetic acid, hot alcohol, and CS_2, slightly in ligroin. Prepared by heating the acid (Spiegel, *B.* 14, 1690).

Tetra-hydro-cornicularic acid $C_{17}H_{18}O_3$ or $C_6H_5.CH_2.CH(OH).CH_2CH(C_6H_5).CO_2H$(?). *Di-phenyl-oxy-valeric acid.* Thick colourless oil. Formed by reduction of di-hydro-cornicularic acid with sodium amalgam (Spiegel, *B.* 14, 1692).

Lactone $C_{17}H_{16}O_2$. [71°]. Flat colourless needles. Sol. alcohol, ether, and benzene, sl. sol. ligroïn, insol. water. Formed by boiling the acid with water (Spiegel, *B.* 14, 1692).

***Iso*-Di-hydro-cornicular-lactone** $C_{17}H_{14}O_2$. [c. 105°]. Colourless needles. Formed as a by-product in the reduction of pulvic acid (Spiegel, *B.* 15, 1546).

CORNIN. A crystalline bitter substance which may be extracted by water from the root of *Cornus florida* (Geiger, *A.* 14, 206). Ppd. by lead subacetate.

CORTICIC ACID $C_{12}H_{10}O_8$? An amorphous acid said to exist in cork (Siewert, *Z.* 1868, 383).

CORYDALINE $C_{18}H_{19}NO_4$. [130°]. Occurs in the roots of *Corydalis bulbosa*, *C. fabacea*, and *Aristolochia cava* (Wackenroder, *Kastn. Arch.* (1826); Peschier, *Trommsd. N. J.* 17, 80; Winckler, *Pharm. Centr.* 1832, 38; *A.* 87, 225; Ruickholdt, *A.* 64, 369; Müller, *Vierteljahr. pr. Pharm.* 8, 526; Wicke, *A.* 137, 274). The alkaloid is extracted by dilute acid, and may be isolated after ppn. by sodium phosphotungstate. Short prisms (from strong solutions) or slender needles (from dilute solutions); insol. water, sol. ordinary solvents. Tastes bitter. Ppd. by NaOH from its solution in acids, the pp. being sol. excess. Ppd. by the usual reagents for alkaloids. —B'HCl 5aq: tufts of needles.—$B'_2H_2PtCl_6$: yellow crystalline pp.—$B'H_2SO_4$: needles, sl. sol. water.

Ethylo-iodide B'EtI. Crystalline, sl. sol. water. Not decomposed by aqueous NaOH, but converted by moist Ag_2O into an alkaline hydroxide.—$(B'EtCl)_2PtCl_4$: amorphous pp.

COTARNAMIC ACID *v.* NARCOTINE.

COTARNIC ACID *v.* NARCOTINE.

COTARNINE *v.* NARCOTINE.

COTO BARK. Two kinds of coto bark are exported from Bolivia, one from the interior of the country called cinchona-coto or genuine coto, derived probably from some plant belonging to the Lauraceæ or Terebinthaceæ, rather than to the Rubiaceæ. It is used in cases of diarrhœa and colic, as also for neuralgia, rheumatism and gout. The other kind of coto-bark or paracoto-bark (Jobst a. Hesse), from the banks of the river Mapiri, resembles the former in appearance, though its physiological action is much weaker. True coto bark contains cotoin and dicotoin; the other bark contains paracotoin, hydrocotone, and its dibenzoyl derivative, leucotin, and oxyleucotin; piperonylic acid is present in both (Harz, *Ar. Ph.* [3] 7, 214; Gietl, *ibid.* 221; Wittstein, *ibid.* 219; Burkart, *Med. Corres. Artz. Verein Würtemburg*, 1876; Bälz, *Centralblatt Med. Wiss.* 1878; Jobst a. Hesse, *A.* 199, 17). The physiological action of cotoin and paracotoin has been studied by Albertoni (*J.* 1883, 1353, 1488).

Cotoin $C_{22}H_{18}O_6$. [130°].

Preparation.—The finely-powdered coto-bark is exhausted with ether, the extract evaporated to one-tenth, and the residue mixed with warm petroleum; on cooling a black resinous mass separates, the liquid from which on evaporation deposits crystals of cotoin. From the resin the compound is also obtained by boiling with lime, and the solution acidified with acetic acid; from this liquid cotoin is deposited in leaflets or pale golden needles. It is finally purified by charcoal.

Properties.—Prisms or tabular crystals, v. sol. alcohol, chloroform, and benzene, sl. sol. water and petroleum; sol. alkalis and their carbonates, but reprecipitated on acidification. Neutral to litmus. Inactive.

Reactions.—1. With *nitric acid* it gives a blood-red colouration.—2. *Reduces* gold and silver salts and Fehling's solution when warmed.—3. With *ammonia* and $Pb(OAc)_2$ it gives a yellow flocculent pp. $C_{22}H_{12}Pb_3O_6$.—4. Heated with concentrated *acids* or *alkalis* it yields benzoic acid.

Triacetyl derivative $C_{22}H_{15}Ac_3O_6$. [94°]. Prisms, sol. $CHCl_3$ and water.

Tri-bromo-cotoïn. [114°]. Yellow prisms, insol. cold water, decomposed by hot water, sol. alcohol, chloroform, and ether.

Dicotoïn $C_{44}H_{34}O_{11}$. *Anhydride of cotoïn?* [74°-77°]. When crude cotoin is treated with boiling water, crystals of cotoïn at first separate, then leaflets of dicotoïn, which are separated by a sieve. Pale yellow glistening leaflets, sol. alcohol, acetone, ether, and alkalis. By potash it is converted into cotoïn; and by Ac_2O into tri-acetyl-cotoïn (Jobst a. Hesse, *A.* 199, 29).

Paracotoïn $C_{19}H_{12}O_6$. [152°].

Preparation.—Finely divided para-coto bark is extracted with ether, and from the residue left on evaporation a crystalline mass of paracotoïn, oxyleucotin, leucotin, and its di-benzoyl derivative separates out. This is fractionally crystallised from alcohol, when the paracotoïn separates out first.

Properties.—*Pale yellow leaflets, sol. ether and chloroform; of neutral reaction; does not* react with Ac_2O.

Reactions.—1. Sol. *nitric acid* forming a *yellow nitro- product.—2. Br gives an unstable bromo- derivative.—3. On fusion with potash it* yields formic and protocatechuic acids, but when boiled with a solution of *potash* paracumarhydrin is formed thus $C_{19}H_{12}O_6 + 2H_2O = 2C_9H_8O_3 + CO_2$ together with paracotoic acid.

Hydrocotoïn $C_{15}H_{14}O_4$. [98°]. Occurs in para-coto bark. Extracted by dilute soda from the resinous mass obtained after separation of the paracotoïn, leucotin, and oxyleucotin. Large pale yellow prisms, sol. hot water and alcohol, v. sol. chloroform and acetone. With *ferric chloride* and *sulphuric acid* it gives a dark-brown colouration; with *bromine* it gives a bromo- derivative $C_{15}H_{13}BrO_4$, crystallising in monoclinic prisms [147°], sol. ether, chloroform, and alcohol. Further bromination gives a di-bromo- derivative, $C_{15}H_{12}Br_2O_4$, crystallising in prisms [95°]. On fusion with potash it yields hydrocotone and benzoic acid (Jobst a. Hesse, *A.* 199, 57).

Acetyl derivative $C_{15}H_{13}O_3(OAc)$. [83°]. White prisms. V. sol. hot water. Forms a bromo- derivative $C_{15}H_{12}BrAcO_4$, [166°], crystallising in white prisms, sol. chloroform and boiling alcohol.

Hydrocotone $C_{18}H_{21}O_6$. [49°]. (243°). V.D. 11·16. Formed by fusion of leucotin with potash; white prisms, sol. ether, acetone, and chloroform. Heated with concentrated nitric acid it yields di-nitro-cotone $C_{18}H_{20}(NO_2)_2O_6$, which crystallises in brown leaflets of metallic lustre; when heated it explodes, emitting violet vapours.

Di-benzoyl- derivative $C_{18}H_{22}Bz_2O_6$. [113°]. Occurs in the para-coto bark; white prisms, sol. alcohol, ether, and acetone, sl. sol. hot water. Concentrated *nitric acid* forms with it a bluish-green resin. *Sulphuric acid* gives a dark-yellow colouration. On fusion with *potash* it yields hydrocotone and benzoic acid. It is unaltered by acetic anhydride. With *bromine* it yields a di-bromo- derivative $C_{32}H_{30}Br_2O_8$ [147°], crystallising in white prisms, sol. alcohol and acetone, as well as a tetra-bromo- derivative $C_{32}H_{28}Br_4O_8$ [84°], crystallising in octahedra, sol. alcohol and chloroform.

Paracumarhydrin $C_9H_8O_3$. [83°]. Formed by boiling paracotoïn with aqueous KOH. Laminæ; smelling like coumarin; sl. sol. cold water, v. e. sol. alcohol.

Leucotin $C_{34}H_{34}O_2$. [97°]. The chief constituent of the extract of para-coto bark. Separates from the alcoholic mother-liquor in the preparation of para-cotoïn. Small prisms. Sl. sol. boiling water, v. sol. alcohol and ether. Inactive. Not attacked by Ac_2O. HNO_3 gives a bluish-green resin and solution. Potash-fusion gives benzoic, formic, and protocatechuic acids, protocatechuic aldehyde, cotogenin, and hydrocotoïn. Br gives a di-bromo- derivative $C_{34}H_{30}Br_2O_2$ [187°], and a tri-bromo- derivative $C_{34}H_{29}Br_3O_2$ [157°].

Cotogenin $C_{14}H_{14}O_5$. [210°]. Obtained by fusing leucotin with KOH. May be crystallised from HOAc. Gives off pyrocatechin when strongly heated. V. sl. sol. cold alcohol and ether. *Dissolves in alkalis, forming solutions which turn brown in the air.* Fe_2Cl_6 *colours its* alcoholic solution green.

Paracotoïc acid $C_{19}H_{14}O_7$. [108°]. Formed by boiling paracotoïn with dilute alkalis $C_{19}H_{12}O_6 + H_2O = C_{19}H_{14}O_7$. *Yellow amorphous* powder, sol. alcohol and ether, insol. water. The Ba, Pb, and Ca salts (MA'_2) are yellow amorphous pps.

Oxyleucotin $C_{34}H_{32}O_{12}$. [134°]. Occurs in paracoto bark. Prisms (from alcohol). V. e. sol. alcohol and HOAc, m. sol. ether. By heating with conc. HNO_3 it is converted into a bluish-green resin and a bluish-green solution. Inactive. It is not coloured by Fe_2Cl_6. Conc. HCl at 140° gives protocatechuic acid. Potash-fusion gives protocatechuic acid and aldehyde, benzoic acid, formic acid, and cotogenin. Br gives a di-bromo- derivative $C_{34}H_{30}Br_2O_{12}$ [192°], and a tetra-bromo- derivative $C_{34}H_{28}Br_4O_{12}$ [159°].

Paracoto oil. Prepared from the para-coto bark by distillation with superheated steam. Light mobile liquid. S.G. ^{15} ·93, $a = -2{\cdot}12$; separated by fractional distillation into (α) and (β) paracotene, (α), (β) and (γ) paracotole.

(α) **Paracotene** $C_{12}H_{18}$. V.D. 5·17. (160°). S.G. ^{15} ·87. $[\alpha]_D = +9{\cdot}34$. Strongly refractive oil of aromatic odour.

(β) **Paracotene** $C_{11}H_{18}$. (171°). V.D. 4·83. S.G. ^{15} ·88. $[\alpha]_D = -{\cdot}63$. Oil, of faint aromatic odour.

(α) **Paracotole** $C_{15}H_{21}O$. (221°). V.D. 6·17. S.G. ^{15} ·93. $[\alpha]_D = -11{\cdot}87$, isomeric with the oil of cubebs, which it resembles in many respects.

(β) **Paracotole** $C_{28}H_{10}O_2$. (236°). V.D. 12·8. S.G. ^{15} ·95. $[\alpha]_D = -5{\cdot}98$. Oil of faint aromatic odour.

(γ) **Paracotole** $C_{28}H_{40}O_2$. (240°). S.G. ^{15} ·97. $[\alpha]_D = -{\cdot}52$. Turns yellow on exposure from absorption of oxygen (Jobst a. Hesse, *A.* 199, 75).

COTTON *v.* Cellulose.

COUMALIC ACID $C_6H_4O_4$ *i.e.*

$$\begin{array}{l} O-CH=C(CO_2H) \\ | \qquad\qquad\quad | \\ OC-CH=CH \end{array}$$

. *Cumalic acid.* [207°]

Prepared by heating malic acid with H_2SO_4 or $ZnCl_2$, and precipitating the melt in water; the yield is nearly theoretical. The reaction probably consists in the splitting off of formic acid with production of the semi-aldehyde of malonic acid $CH_2{<}^{CHO}_{CO_2H}$, which then undergoes further condensation, forming coumalic acid (Pechmann, *B.* 17, 936). Sublimable. Small colourless prisms. V. sol. alcohol and acetic acid, sl. sol. cold, more sol. hot, water. It reduces ammoniacal silver and copper solutions on boiling. Its aqueous solution is decomposed on boiling. On oxidation it gives fumaric acid. NH_3 forms, in the cold, oxy-pyridine carboxylic acid.

Methyl ether A'Me: [74°]; (c. 260°), long, colourless needles or plates.

Coumal-anilidic acid
$CO_2H.CH:CH.C(CO_2H):CH.NHPh$. (?)

Mono-methyl ether
$CO_2H.CH:CH.C(CO_2Me):CH.NHPh$. [140°].

Formed by the action of aniline on an alcoholic solution of the methyl-ether of coumalic acid (Pechmann a. Welsh, *B.* 17, 2392; *C. J.* 47, 145). Yellow needles, v. sol. hot alcohol, chloroform, and benzene, sl. sol. ether, insol. water. By boiling with aqueous NaOH it is converted into the phenyl derivative of oxy-nicotinic acid—$C_5H_3N(OPh)CO_2H$[1:2:5].

Bromocoumalic acid *v.* vol. i. p. 565.

PARACOUMARHYDRIN *v.* COTO BARK.

***o*-COUMARIC ACID** $C_9H_8O_3$. *o-Oxy-cinnamic acid. o-Oxy-phenyl-acrylic acid.* Mol. w. 164. [208°]. V.D. 6·5 (calc. 6·66).

Occurrence.—In melilot (*Melilotus officinalis*) and in the leaves of *Angræcum fragrans* (Zwenger, *A. Suppl.* 8, 30).

Formation.—From *o*-amido-cinnamic acid by the diazo- reaction (Fischer, *B.* 14, 479; *A.* 221, 274).

Preparation.—Coumarin (10 g.) is added to a solution of sodium (3·5 g.) in dry alcohol (65 c.c.), and the mixture heated for 1½ hours. The product is diluted and evaporated to a small bulk. The coumaric acid is ppd. by HCl. The pp. is dissolved in Na_2CO_3Aq, freed from unaltered coumarin by shaking with ether, the acid is reppd. by HCl and crystallised from water (Ebert, *A.* 226, 347; *cf.* Delalande, *A. Ch.* [3] 6, 343; *A.* 45, 333; Bleibtreu, *A.* 59, 183).

Properties.—Long needles, v. sl. sol. cold water and ether, v. sol. alcohol, insol. $CHCl_3$ and CS_2. Not volatile with steam. Decomposed on distillation with formation of phenol. Its solution in alkalis is yellow with green fluorescence. Conc. HBrAq slowly changes it in the cold into its anhydride, coumarin.

Reactions.—1. *Potash-fusion* gives acetic and *o*-oxy-benzoic acids.—2. *Sodium amalgam* gives *o*-oxy-phenyl-propionic acid (Tiemann a. Herzfeld, *B.* 10, 286).—3. *Bromine* (1 mol.) added to its solution in CS_2 gives a white crystalline substance [c. 111°] (? di-bromo-*o*-oxy-phenyl-propionic acid), which, when exposed to the air, gives off HBr, and yields (β)-di-bromo-coumarin [177°].

Salts.—BaA'_2 aq: nodules, v. sol. water.—PbA'_2: crystalline pp.—ZnA'_2: needles, sl. sol. cold water.—AgA'.

Constitution.—Like cinnamic, fumaric, and citraconic acids, coumaric acid is a symmetrical derivative of ethylene, so that it might be expected to exist in two modifications. These two modifications are found in its alkyl derivatives. The existence of two modifications might also be accounted for by ascribing to one of them the formula  (Anschütz, *A.* 239, 161; 240, 133). Except as regards boiling-point, the physical properties of the (α)-coumaric ethers stand to those of their (β)-isomerides exactly as those of citraconic and maleic ethers stand to those of mesaconic and fumaric ethers respectively (Perkin, *C. J.* 39, 559).

(α)- (or *Allo-*) ***Methyl derivative*** $C_6H_4(OMe).CH:CH.CO_2H$. [89°]. Formed by heating coumarin with NaOH (2 mols.) and MeI (1 mol.) at 150° (Perkin, *C. J.* 39, 409). Monoclinic crystals (from CS_2). $a:b:c = \cdot677:1:1\cdot122$; $\beta = 87° 12'$. V. e. sol. alcohol, m. sol. ligroïn. Changes into the (β)-isomeride on boiling, or even by exposing a concentrated alcoholic solution to sunlight. Sodium amalgam reduces it, as well as its (β)-isomeride, to the methyl derivative of oxy-phenyl-propionic acid. Br in CS_2 gives the methyl ether of (α)-di-bromo-*o*-oxy-(β)-phenyl-propionic acid (*v.* vol. i. p. 603). Undiluted bromine forms the methyl-ether of tri-bromo-oxy-phenyl-propionic acid. HNO_3 gives the same di-nitro- derivative as with its (β)-isomeride. Fuming HI unites in the cold, and on adding Na_2CO_3 there is formed $C_6H_4(OMe)CH:CH_2$. $KMnO_4$ oxidises it to [2:1] $C_6H_4(OMe)CO_2H$.—BaA'_2.—**Methyl ether** [2:1]$C_6H_4(OMe).CH:CH.CO_2Me$. (276°). S.G. $\frac{15}{15}$ 1·140; $\frac{30}{30}$ 1·278. Formed by heating coumarin, MeOH, and MeI for 3 hours at 100°. Converted by NH_3 at 150° into the amide of the (β)-isomeride.

(β)-***Methyl derivative*** [2:1]$C_6H_4(OMe).CH:CH.CO_2H$. [183°]. Formed by heating [2:1]$C_6H_4(OMe).CHO$ (2 pts.) with NaOAc (1 pt.) and Ac_2O (3 pts.) at 175° (Perkin, *C. J.* 31, 414). Formed also by heating its (α)-isomeride. Small monoclinic prisms (from xylene) $a:b:c = \cdot441:1:\cdot807$; $\beta = 64° 41'$. M. sol. alcohol. Br in CS_2 gives the methyl derivative of (β)-di-bromo-oxy-phenyl-propionic acid (*v.* vol. i. p. 603). Undiluted bromine forms the methyl ether of tri-bromo-oxy-phenyl-propionic acid. $KMnO_4$ gives $C_6H_4(OMe).CO_2H$ (Tiemann a. Will, *B.* 15, 2078). *Potash-fusion* gives salicylic acid. HNO_3 forms a di-nitro-derivative [193°].—**Methyl ether** $C_6H_4(OMe).CH:CH.CO_2Me$. [293°]. S.G. $\frac{15}{15}$ 1·1486; $\frac{30}{30}$ 1·1362. V.D. 6·5 (calc. 6·6). M.M. 2·389. μ_D 1·5905 at 10°. Obtained by means of PCl_5 and HOMe. Formed also by heating its (α)-isomeride. With Br in CS_2 it gives $C_6H_4(OMe).CHBrCHBr.CO_2Me$ [68°] and an isomeride [125°].

Amide $C_6H_4(OMe).CH:CH.CONH_2$. [192°]. Small needles (from alcohol).

(α)- (or *Allo-*) ***Ethyl derivative*** [2:1]$C_6H_4(OEt)CH:CH.CO_2H$. [102°] (F. a. E.); [104°] (P.). From alcohol, sodium (3·2 g.), coumarin (10 g.) and EtI (12 g.) (Fittig a. Ebert, *A.* 216, 142; Perkin, *C. J.* 39, 412). White plates (from water), or tables (from dilute alcohol). V. sl. sol. cold water, sl. sol. hot water, v. sol. alcohol and ether. Sparingly volatile with steam. *Reactions.*—1. On distillation an oil is got, whence Na_2CO_3 extracts the (β)-isomeride; the yield is 30 p.c.—2. $KMnO_4$ gives ethyl-salicylic aldehyde and acid.—3. Sodium amalgam forms the ethyl derivative of oxy-phenyl-propionic acid.—4. Br forms a dibromide [155°]. **Salts.**—$(C_{11}H_{11}O_3)_2Ba$ 2aq.—CaA'_2 2aq. S. 2·11 at 21°.

Ethyl ether $C_6H_4(OEt).CH:CH.CO_2Et$. (291°). S.G. $\frac{15}{15}$ 1·084; $\frac{30}{30}$ 1·074. $\mu_D = 1\cdot558$. From coumarin (14½ g.), NaOH (8 g.) and water, by evaporating to a small bulk and heating the residue with alcohol and EtI (32 g.) at 100°.

(β)-***Ethyl derivative*** $C_6H_4(OEt)CH:CH.CO_2H$. [133°] (E. a. F.); [135°] (P.). Formed, together with the (α)-isomeride by treating *o*-coumaric acid with NaOEt and EtI. Formed also from the (α)-isomeride by distillation, or by long heating to a high temperature (Fittig a. Ebert, *A.* 216, 144). Obtained by heating $C_6H_4(OEt)CHO$ with NaOAc and acetic anhydride at 160° (Perkin, *C. J.* 39, 413). Needles (from water), or prisms (from alcohol). V. sl sol. cold water, sl. sol. hot water. V. e. sol. alcohol or ether. The Na salt is oxidised by $KMnO_4$ to ethyl-salicylic aldehyde and ethyl-salicylic acid. Sodium amalgam forms the ethyl derivative of oxy-phenyl propionic acid. Br forms a dibromide [155°]. Salts.—$(C_{11}H_{11}O_3)_2Ca$ 2aq. S. ·43 at 21°.—BaA'_2 4aq. Ethyl ether $C_6H_4(OEt).CH:CH.CO_2Et$. (303°). S.G. $\frac{15}{15}$ 1·09. Formed by treating the preceding with PCl_5, followed by alcohol. Formed also by boiling the (*a*)-isomeride for some time.

Acetyl derivative
$C_6H_4(OAc).CH:CH.CO_2H$. [146°]. Formed by gently heating salicylic aldehyde (3 pts.) with NaOAc (4 pts.) and Ac_2O (5 pts.) (Tiemann a. Herzfeld, *B.* 10, 284). Needles (from water). V. sol. hot water, alcohol, and ether. Converted by dilute KOHAq into coumaric acid; and by heating above 150° into HOAc and coumarin.

Carboxy-methyl derivative
$CO_2H.CH_2.O.C_6H_4.CH:CH.CO_2H$. *o-Coumar-oxy-acetic acid.* [190°]. Formed by heating *o*-aldehydo-phenoxy-acetic acid (1 pt.) with acetic anhydride (5 pts.) and sodium acetate (3 pts.) to boiling for 1 or 2 hours (Rossing, *B.* 17, 2997). Yellow needles. V. sol. alcohol, ether, and hot water, sl. sol. benzene, chloroform, and cold water. Sublimable.

Di-bromide 
$$C_6H_4\left<\begin{matrix}CHBr.CHBr.CO_2H\\O.CH_2.CO_2H\end{matrix}\right..$$

[220°]. White needles; sl. sol. benzene, chloroform, and water, v. sol. alcohol and ether.

Anhydride  [176°].

$$C_6H_4\left<\begin{matrix}CH:CH.CO\\O.CH_2.CO\end{matrix}\right>O.$$

Crystalline solid. V. sol. alcohol and ether, sl. sol. water. Formed by heating the acid with phosphoric acid.

Di-bromide  [c.213°].

$$C_6H_4\left<\begin{matrix}CHBr.CHBr.CO\\ \qquad\qquad\quad |\\O.CH_2.CO\ -O\end{matrix}\right..$$

Orange-yellow needles; v. sol. alcohol and ether, sl. sol. water and benzene (Rossing, *B.* 17, 3001).

Bromo-coumaric acid *v.* vol. i. p. 564.

***m*-Coumaric acid**
[3:1]$C_6H_4(OH).CH:CH.CO_2H$. [191°]. Formed by heating *m*-oxy-benzaldehyde with acetic anhydride and sodium acetate; or by boiling di-azocinnamic acid with water (Tiemann a. Ludwig, *B.* 15, 2048). White prisms. Sol. alcohol, ether, benzene, and hot water.

Acetyl derivative
$C_6H_4(OAc).CH:CH.CO_2H$. [151°]. White needles, sol. alcohol, ether, and hot water.

Methyl derivative
$C_6H_4(OMe).CH:CH.CO_2H$. [115°]. Long white needles, sol. alcohol, ether, and benzene, sl. sol. hot water (Tiemann a. Ludwig, *B.* 15, 2048).

Carboxy-methyl derivative $C_{11}H_{10}O_5$ *i.e.* $C_6H_4(O.CH_2.CO_2H).CH:CH.CO_2H$ [1:3]. *m-Phenoxy-acetic-acrylic acid. m-Cumaroxy-acetic acid. Phenyl-glycollic-m-acrylic acid.* [219°]. Prepared by heating *m*-aldehydo-phenoxy-acetic acid with sodium acetate and acetic anhydride. White needles (from hot water). V. sol. alcohol, ether, and acetic acid, sl. sol. cold water. The Ag, Pb, Cu, and Fe salts are sparingly soluble pps. (Elkan, *B.* 19, 3047).

***p*-Coumaric acid** $C_6H_4(OH).CH:CH.CO_2H$. *p-Oxy-cinnamic acid. p-Oxy-phenyl-acrylic acid. Naringenic acid.* [206°].

Preparation.—1. 2½ kilos. of aloes are boiled for two hours with 5 litres of water and 400 g. conc. H_2SO_4; after cooling the liquor is decanted and the residue again boiled with 2 litres of water, the combined extracts are evaporated to ⅓, and when cold extracted with ether. The crude *p*-coumaric acid (yield: 1·5 to 1·8 p.c.) left on evaporating the ether is purified by conversion into the barium salt (Hlasiwetz, *A.* 136, 31; Eigel, *B.* 20, 2527).—2. *p*-Oxy-benzaldehyde (5 pts.) is heated at 175° with dehydrated sodium acetate (8 pts.) and acetic anhydride (10 pts.); the yield is 70 p.c. of the oxy-benzaldehyde (Tiemann a. Herzfeld, *B.* 10, 63, 283; Eigel). 3. By heating *p*-diazo-cinnamic acid with water; small yield (Gabriel, *B.* 15, 2301).—4. Together with phloroglucin by boiling naringenin with conc. aqueous NaOH (Will, *B.* 20, 299).

Properties.—Thick warts (anhy.) or long needles (with *x*aq). V. sl. sol. cold water, v. sol. hot water, v. e. sol. alcohol and ether, sl. sol. benzene, insol. ligroïn. Fe_2Cl_6 colours the alcoholic solution brown. Sodium-amalgam gives *p*-oxy-phenyl-propionic acid. Potash-fusion forms *p*-oxy-benzoic acid (Barth, *B.* 12, 1259).

Salts.—NH_4A'aq: monoclinic tables.—$CdA'_2$3aq.—$CuA'_2$6aq.—AgA'.

Methyl derivative
$C_6H_4(OMe).CH:CH.CO_2H$. [169°] (E.); [171°] (P.). Formed by heating anisic aldehyde with acetic anhydride and sodium acetate at 180° (yield: 70 p.c. of the anisic aldehyde), or by saponification with KOH of the di-methyl-ether $C_6H_4(OMe).CH:CH.CO_2Me$ formed by heating the acid with methyl iodide and KOH. Occurs among the products of the action of KOH and MeI upon tyrosine (Körner a. Menozzi, *G.* 11, 549). Formed also by oxidising the methyl derivative of methyl oxy-styryl ketone with NaOCl (Einhorn a. Grabfield, *A.* 243, 363). Yellow needles, m. sol. alcohol, hot water, and HOAc; sl. sol. cold water and chloroform (Perkin). Gives when heated the methyl derivative of vinyl-phenol $CH_2:CH.C_6H_4OMe$. This body is also formed by successive treatment with HI and Na_2CO_3 (Perkin, *C. J.* 33, 214).—A'Na.—AgA' (Eigel, *B.* 20, 2527).

Methyl ether $C_6H_4(OMe).CH:CH.CO_2Me$. [89°]. (303°). Laminæ. In chloroform solution it takes up bromine, with production of $C_6H_4(OMe)CHBr.CHBr.CO_2Me$ [118°] (Valentini, *G.* 16, 424; Perkin, *C. J.* 39, 439).

Chloride $C_6H_4(OMe).CH:CH.COCl$. [50°].

Amide $C_6H_4(OMe).CH:CH.CONH_2$. [186°].

Acetyl derivative
$C_6H_4(OAc).CH:CH.CO_2H$. [c. 195°]. Formed by heating sodium *p*-oxy-benzoic aldehyde $C_6H_4(ONa).CHO$ with NaOAc and Ac_2O (Tiemann a. Herzfeld, *B.* 10, 65). Felted groups of slender needles (from hot water). Sublimes readily. Sol. boiling water, alcohol, ether, and HOAc, v. sl. sol. cold water, benzene, and $CHCl_3$.

Carboxy-methyl derivative $C_{11}H_{10}O_5$ *i.e.* $C_6H_4(O.CH_2.CO_2H).CH:CH.CO_2H$ [1:4]. *p-Cumaroxy-acetic acid. Phenyl-glycollic-p-acrylic acid.* [225°]. Prepared by boiling a mixture of *p*-aldehydo-phenoxy-acetic acid (1 pt.), sodium acetate (1 pt.), and acetic anhydride (3 pts.) for 5 hours. Warty crystals. Sol. benzene and benzoline, v. sol. alcohol, ether, and acetic acid, sl. sol. cold water. The Ag, Pb, Cu, and Fe salts are sparingly soluble pps. (Elkan, *B.* 19, 3046).

Di-bromide of coumaric acid *v.* DI-BROMO-OXY-PHENYL-PROPIONIC ACID.

Hydro-coumaric acid *v.* OXY-PHENYL-PROPIONIC ACID.

Other derivatives are described as NITRO-COUMARIC ACID, DI-OXY-CINNAMIC ACID, and OXY-AMIDO-CINNAMIC ACID.

***o*-COUMARIC ALDEHYDE**
$C_6H_4(OH).CH:CH.COH$. *Oxy-cinnamic aldehyde.* [133°]. Long slender needles. V. sol. alcohol and ether, sl. sol. water. Fe_2Cl_6 gives a red pp. Formed by the decomposition of its glucoside under the influence of emulsin (Tiemann a. Kees, *B.* 18, 1962).

Glucoside [2:1]$C_6H_4(OC_6H_{11}O_5).C_2H_2.COH$. *Gluco-coumaric aldehyde.* [199°]. Formed by adding a few drops of dilute NaOH to a mixture of helicin [2:1]$C_6H_4(OC_6H_{11}O_5).COH$ and acetic aldehyde. This condensation even takes place in dilute aqueous solution and at a low temperature (Tiemann a. Kees, *B.* 18, 1958). Fine white needles (containing aq). V. sol. hot water and alcohol, insol. ether and chloroform. Lævorotatory. By emulsin it is split up into coumaric aldehyde and glucose. Sodium amalgam reduces it to gluco-coumaryl alcohol

$$C_6H_4(OC_6H_{11}O_5).C_2H_2.CH_2(OH).$$

Phenyl hydrazide of the glucoside $C_6H_4(OC_6H_{11}O_5).C_2H_2.CH:N_2HPh$: [132°]; sol. alcohol and hot water, nearly insol. cold water.

Oxim of the glucoside $C_6H_4(OC_6H_{11}O_5).C_2H_2.CH:NOH$: [230°]; long white needles (containing 2aq); v. sol. hot water, less sol. alcohol, insol. ether.

***m*-Coumaric aldehyde**
[3:1] $C_6H_4(OH)CH:CH.CHO$. [100°]. From *m*-aldehydo-phenoxy-acetic acid, aldehyde, and dilute NaOHAq (Elkan, *B.* 19, 3048).

***p*-Coumaric aldehyde**
[4:1] $C_6H_4(OH)CH:CH.CHO$. [182°]. From *p*-aldehydo-phenoxy-acetic acid in the same way.

COUMARILIC ACID $C_9H_6O_3$ *i.e.* $C_6H_4(OH).C{:}C.CO_2H$ or $C_6H_4<\genfrac{}{}{0pt}{}{CH}{O}>C.CO_2H$. *o-Oxy-phenyl-propiolic acid.* [191°] (F.); [193°] (P.). (c. 312°). Formed by treating (*a*)-bromo-coumarin with hot alcoholic KOH (Perkin, *C. J.* 24, 45; Fittig, *A.* 216, 162). Long needles (from water); v. e. sol. alcohol, m. sol. water, sl. sol. chloroform and CS_2. Not attacked by Br or conc. HBr. Potash-fusion gives salicylic and acetic acids. $KMnO_4$ forms only CO_2. Sodium amalgam reduces it to hydrocoumarilic acid $C_9H_8O_3$.

Salts.—AgA'.—CaA'$_2$ 3aq.—BaA'$_2$ 4aq.

Ethyl ether EtA': [27°]; (274° at 720 mm.) (Hantzsch, *B.* 19, 2401).

Methyl derivative $C_6H_4(OMe).C{:}C.CO_2H$. [126°]. From the methyl-derivative of *exo*-bromo-coumaric acid and dilute KOH (Perkin, *C. J.* 39, 423). Needles (from CS_2).

Bromo-coumarilic acid
$C_6H_3Br<\genfrac{}{}{0pt}{}{CH}{O}>C.CO_2H$. [250°]. From (*a*)-di-bromo-coumarin and alcoholic KOH (Perkin, *C. J.* 24, 45). Needles, sl. sol. water, v. sol. alcohol.

Methyl derivative $C_6H_2Br(OMe).C{:}C.CO_2H$. [168°]. Prepared from $C_6H_2Br(OMe).C_2H_2Br_2.CO_2H$ and aqueous KOH (Perkin, *C. J.* 39, 419). Small needles (from benzene).

***p*-Oxy-cumarilic acid** *Methyl derivative* $C_6H_3(OMe)<\genfrac{}{}{0pt}{}{CH}{O}>C.CO_2H$[4:2:1]. [196°]. Formed by boiling bromo-umbelliferon-methyl ether $C_6H_3(OMe)<\genfrac{}{}{0pt}{}{CH:CBr}{O.CO}$ with conc. alcoholic KOH. Long white needles. V. sol. alcohol and ether, scarcely sol. cold water, more readily in hot. Slightly volatile with steam.—BaA'$_2$ 4aq: white crystalline solid (Will a. Beck, *B.* 19, 1783).

Ethyl derivative $C_{11}H_{10}O_4$ *i.e.* $C_6H_3(OEt)<\genfrac{}{}{0pt}{}{CH}{O}>C.CO_2H$ [4:2:1]. [163°]. Formed by boiling bromo-umbelliferon-ethyl ether $C_6H_3(OEt)<\genfrac{}{}{0pt}{}{CH:CBr}{O.CO}$ with conc. alcoholic KOH. Long felted needles (Will a. Beck, *B.* 19, 1785).

Hydro-coumarilic acid $C_9H_8O_3$ *i.e.* $C_6H_4<\genfrac{}{}{0pt}{}{CH_2}{O}>CH.CO_2H$. [117°]. (299°). Formed by treating coumarilic acid with sodium amalgam, and extracted by ether from the acidified product (Fittig, *A.* 216, 166). Pearly plates (from water); very volatile with steam. V. sol. alcohol and ether, m. sol. water. Partially decomposed on distillation, yielding a phenol. Gives phenol on distillation with lime.

Salts.—AgA'.—CaA'$_2$ 2aq. BaA'$_2$ 2aq.

Ethyl ether EtA'. [23°]. (273°).

***p*-Oxy-hydrocoumarilic acid** *Methyl derivative* $C_{10}H_{10}O_4$ *i.e.* $C_6H_3(OMe)<\genfrac{}{}{0pt}{}{CH_2}{O}>CH.CO_2H$ [4:2:1]. [114°]. Formed by reduction of the methyl derivative of oxy-coumarilic acid $C_6H_3(OMe)<\genfrac{}{}{0pt}{}{CH}{O}>C.CO_2H$ with sodium-amalgam. Hard prisms. V. sol. ordinary solvents. Volatile with steam (Will a. Beck, *B.* 19, 1783).

Ethyl derivative $C_{11}H_{12}O_4$ *i.e.* $C_6H_3(OEt)<\genfrac{}{}{0pt}{}{CH_2}{O}>CH.CO_2H$ [4:2:1]. [119°]. Formed by reduction of ethoxy-coumarilic acid $C_6H_3(OEt)<\genfrac{}{}{0pt}{}{CH}{O}>C.CO_2H$ with sodium amalgam. Hard white needles (Will a. Beck, *B.* 19, 1785).

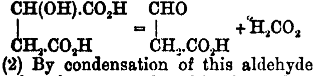
Di-oxy-coumarilic acid *Di-ethyl derivative* $C_6H_2(OEt)_2<\genfrac{}{}{0pt}{}{O}{CH}>C.CO_2H$. [195°]. From bromo-æsculetic ether $C_6H_2(OEt)_2<\genfrac{}{}{0pt}{}{O}{C_2HBr}>CO$ and alcoholic KOH (Will, *B.* 16, 2119). Slender needles.

V. also METHYL-COUMARILIC ACID.

COUMARIN $C_9H_6O_2$ *i.e.* $C_6H_4<\begin{array}{l}CH{:}CH\\ \quad\;\;|\\ O\,.\,CO\end{array}$. Mol. w. 146. [67°]. (290°).

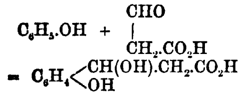
Occurrence.—In Tonka beans, the fruit o *Coumaruma odorata*, or *Dipteryx odorata*, a small white crystals between the seed coatin and the kernel; found in woodruff (*Asperul odorata*), in *Melilotus officinalis* (as melilotat $C_{18}H_{16}O_5$ [128°]), in the flowers of sweet-scente vernal grass (*Anthoxanthum odoratum*), in th leaves of Faham (*Angræcum fragrans*), of an other orchid, *Orchis fusca*, and of *Liatris odoratissima* (Guibourt, *Histoire des Drogues Simples*; Boullay a. Boutron-Chaillard, *J. Ph.* 9, 480; Delalande, *A. Ch.* [3] 6, 343; Bleibtreu, *A.* 59, 177; Procter, *Rép. chim. App.* 1861, 143; Fontana, *B. J.* 14, 311; Guillemette, *A.* 14, 328; Kossmann, *A.* 52, 387; Gobley, *A.* 76, 354).

Formation.—1. By boiling salicylic aldehyde with Ac_2O and NaOAc (Perkin, *C. J.* 21, 53, 181; *cf.* vol. i. p. 158).—2. Together with HOAc by heating acetyl-coumaric acid (Tiemann a. Herzfeld, *B.* 10, 287).—3. By the action of Br at 170° on the anhydride of *o*-oxy-phenyl-propionic acid (Hochstetter, *A.* 226, 360).—4. By heating phenol with malic acid and H_2SO_4 or $ZnCl_2$. The reaction probably takes place in the following stages: (1) By splitting off formic acid the semi-aldehyde of malonic acid is formed.



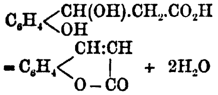
$$\begin{array}{l}CH(OH).CO_2H\\ |\\ CH_2.CO_2H\end{array} = \begin{array}{l}CHO\\ |\\ CH_2.CO_2H\end{array} + H_2CO_2$$

(2) By condensation of this aldehyde with the phenol an oxy-phenyl-lactic acid is produced—



$$C_6H_5.OH + \begin{array}{l}CHO\\ |\\ CH_2.CO_2H\end{array} = C_6H_4<\begin{array}{l}CH(OH).CH_2.CO_2H\\ OH\end{array}$$

(3) By splitting two mols. of water from this body a cumarin is formed:



$$C_6H_4<\begin{array}{l}CH(OH).CH_2.CO_2H\\ OH\end{array} = C_6H_4<\begin{array}{l}CH{:}CH\\ \quad\; |\\ O-CO\end{array} + 2H_2O$$

(Pechmann, *B.* 17, 929).

Properties. — Triclinic crystals, *a*:*b*:*c* = ·8833:1:·3696 (Scacchi, *G.* 14, 568). Peculiar odour. M. sol. hot water, v. e. sol. alcohol, insol. cold aqueous baryta, but dissolves on boiling. Ether will not extract it from the solution, but acids, even CO_2, re-ppt. it. It appears, however, to have formed the barium salt of an oxy- acid, which is not *o*-coumaric acid, unless the boiling is prolonged after the coumarin is dissolved (Ebert, *A.* 216, 139). Coumarin dissolves in boiling aqueous K_2CO_3 without evolution of CO_2, apparently forming a compound with it. $BaCO_3$ has no action on coumarin.

Reactions.—1. Boiling conc. aqueous KOH gives *o*-coumaric acid.—2. *Potash-fusion* forms acetic and salicylic acids.—3. Gaseous HBr passed into its solution forms large transparent crystals [c. 45°] of what is probably an addition-product. Exposed to the air, these crystals quickly lose HBr, leaving pure coumarin (Ebert, *A.* 226, 347).—4. *Sodium amalgam* reduces it to oxy-phenyl-propionic acid. In alcoholic solution sodium amalgam forms di-hydro-di-coumaric acid $C_{18}H_{18}O_6$, which is sl. sol. cold water, forms the salts Na_2A''10aq, CaA'' 2aq, PbA'', CuA''2aq, and Ag_2A'', and an anhydride $C_{18}H_{16}O_5$ [222°] (Zwenger, *A. Suppl.* 8, 32).

Combinations with bases.—$C_9H_6O_2 2KOH$.—$C_9H_6O_2 2NaOH$. Obtained by boiling coumarin (1 mol.) with aqueous NaOH (2 mols.) for a few minutes. Deliquescent; at 150° it becomes $C_9H_6O_2Na_2O$.—$C_9H_6O_2Ba(OH)_2$.—$C_9H_6O_2 2PbO$.—$C_9H_6O_2Ag_2O$: yellow pp. Formed by adding $AgNO_3$ to the yellow solution of coumarin in aqueous KOH (Perkin, *C. J.* 22, 192; Williamson, *C. J.* 28, 850).

Oxim $C_6H_4<\substack{C_2H_2\\ O}>C(NOH)$: [131°]. Formed by the action of hydroxylamine upon thiocoumarin in alcoholic solution. Long white needles. V. sol. alcohol, ether, and benzene; sol. hot water, nearly insol. cold. It is very stable to alkalis and acids, but by long heating with HCl it is split up into coumarin and H_2NOH.

Ethyl-oxim $C_6H_4<\substack{C_2H_2\\ O}>C(NOEt)$: [50°]. Formed by ethylation of the oxim. Colourless plates. V. sol. alcohol, ether, and benzene, insol. water.

Phenyl-hydrazide

$C_6H_4<\substack{C_2H_2\\ O}>C(N_2HPh)$: [144°]. Formed by heating thiocoumarin with phenyl-hydrazine in alcoholic solution. Long yellow needles. V. sol. benzene and ether, sol. hot alcohol, sl. sol. cold alcohol, insol. water. Dissolves in H_2SO_4 with a green colour (Tiemann, *B.* 19, 1662).

Coumarin bromide $C_9H_6O_2Br_2$. [105°]. From coumarin (7 pts.) and Br (8 pts.) in CS_2 (Perkin, *C. J.* 17, 368; 9, 37). Oblique prisms (from alcohol); v. sol. alcohol, but decomposed by boiling therewith. Gives off Br a little above its melting-point. Alcoholic KOH converts it into (*a*)-bromo-coumarin (*v.* vol. i. p. 564).

Chloro-coumarin *v.* p. 57.

Di-coumarin $C_{18}H_{10}O_4$ *i.e.*

$C_6H_4<\substack{CH\\ O.CO}\gg C-C\ll\substack{CH\\ CO.O}>C_6H_4$? [above 330°]. From salicylic aldehyde, sodium succinate, and Ac_2O at 100° (Dyson, *C. J.* 51, 62). Insol. ether, alcohol, and benzene, sl. sol. chloroform, and HOAc. Slowly dissolves in boiling NaOHAq, but is reppd. unchanged by acids. Reduced in alkaline solution by sodium amalgam to hydro-di-coumaric acid $C_{18}H_{14}O_5$, which is insol. water, sol. $CHCl_3$ and benzene. It forms the salts $BaA'_2$6aq and AgA'. At 133° hydrodicoumaric acid splits up into water and its anhydride hydrodicoumarin $C_{18}H_{12}O_4$ [256°]. It is reconverted into the acid by long heating with conc. NaOHAq or with HOAc. Bromine acting on hydrodicoumarin in $CHCl_3$ forms $C_{18}H_{11}BrO_4$.

Hydro-dicoumaric acid is perhaps

$$C_6H_4<\begin{array}{l}CH\\ O.CO\end{array}\gg C.CH<\begin{array}{l}CH_2.C_6H_4.OH.\\ CO_2H\end{array}$$

Reduced in aqueous alkaline solution by sodium amalgam it gives the dihydro-dicoumaric acid $C_{18}H_{18}O_6$ or

$$\begin{array}{r}HO.C_6H_4.CH_2\\ CO_2H\end{array}>CH.CH<\begin{array}{l}CH_2.C_6H_4OH\\ CO_2H\end{array}$$

not identical with Zwenger's acid. Its salts are $CaA'_2$6aq.—Ag_2A''. It forms an anhydride $C_{18}H_{14}O_4$ [224°].

Homologues of coumarin. Obtained by the action of fatty anhydrides upon sodium *o*-oxy-benzoic aldehyde (Perkin, *C. J.* 28, 10). They are described as anhydrides of the corresponding oxy- acids.

Oxy-coumarins. Described as *anhydrides* of DI-OXY-CINNAMIC ACID, &c. The di-oxy-benzenes and their homologues may be converted by treatment with malic acid and H_2SO_4 into oxy-coumarins, and by aceto-acetic ether and a dehydrating agent into oxy-methyl-coumarins. When excess of aceto-acetic ether is used, small quantities of polycoumarins are also formed (Pechmann, *B.* 17, 929, 2191; 20, 1328).

Thus from resorcin may be prepared umbelliferon  [224°],

(*β*)-methyl-umbelliferon

 [248°],

and di-methyl-di-coumarin

Orcin gives rise to

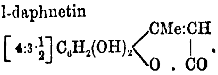
 [248°] and

 [250°].

Pyrogallol forms daphnetin

 [255°], and

(*β*)-methyl-daphnetin



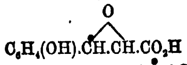
Phloroglucin gives

 [284°], and

'tri-methyl-tri-coumarin'

Imido-dihydro-coumarin 
Benzoyl derivative  [171°].

Fine white needles; sol. warm ether, alcohol, benzene and acetic acid; insol. water. Formed by boiling an acetic acid solution of the benzoyl derivative of *o*-oxy-phenyl-*αβ*-imido-propionic anhydride $\left\{C_6H_4(OH).C_2H_2(NBz).CO\right\}_2O$. By treatment with concentrated aqueous NaOH it is converted into *o*-oxy-phenyl-glycidic acid



(Plöchl a. Wolfrum, *B.* 18, 1184; *cf.* Rebuffat, *G.* 15, 527).

Cumarin oxide 
Inner anhydride of o-oxy-phenyl-glycidic acid. [153°]. Long needles or prisms. V. sol. ether and warm alcohol. Formed by boiling *o*-oxy-phenyl-glycidic acid with dilute H_2SO_4. By boiling with water it is partly converted back again into oxy-phenyl-glycidic acid (Plöchl a. Wolfrum, *B.* 18, 1187).

COUMARIN - CARBOXYLIC ACID

 [187°].

Formed by heating salicylic aldehyde, malonic acid, and glacial HOAc at 100° (Stuart, *C. J.* 49, 366). White needles (from water). It is not decomposed by boiling with water or on melting, but on heating above 190° it evolves CO_2, leaving coumarin.

Salts.—BaA'_2 and AgA' are white pps.

COUMARIN DIHYDRIDE *v. Anhydride of* Oxy-phenyl-propionic acid.

COUMARONE C_8H_6O *i.e.* $C_6H_4\left\langle\begin{matrix}CH\\O\end{matrix}\right\rangle CH$. (169°). Formed by heating coumarilic acid with lime, CO_2 being split off (Fittig a. Ebert, *A.* 216, 168; 226, 347). Formed also by boiling *o*-aldehydo-phenoxy-acetic acid with Ac_2O and NaOAc (Rössing, *B.* 17, 3000). Heavy oil; volatile with steam. Not attacked by sodium amalgam. Converted by a drop of H_2SO_4 into a reddish-white amorphous mass.

Dibromide $C_8H_6OBr_2$. [86°]. Prisms (from CS_2). Converted by boiling with water into coumarone and other products.

Bromo-coumarone C_8H_5BrO. [36°]. From coumarone dibromide and alcoholic KOH. Needles (from dilute alcohol). V. e. sol. alcohol and ether, insol. water and alkalis.

p-**Methoxy-coumarone** $C_9H_8O_2$ *i.e.* $C_6H_3(OMe)\left\langle\begin{matrix}CH\\O\end{matrix}\right\rangle CH$ [4:2:1]. (179°). Formed by dry-distillation of the silver salt of methoxy-coumarilic acid $C_6H_3(OMe)\left\langle\begin{matrix}CH\\O\end{matrix}\right\rangle C.CO_2H$ in a stream of CO_2. Colourless oil, having a strong odour of flowers. Somewhat heavier than water. Very volatile with steam (Will a. Beck, *B.* 19, 1784).

Oxy-methyl-coumarone $C_9H_8O_2$ *i.e.* $\left[4\ \begin{smallmatrix}1\\2\end{smallmatrix}\right] C_6H_3(OH)\left\langle\begin{matrix}CMe\\O\end{matrix}\right\rangle CH$. [97°]. Formed, by loss of CO_2, by distillation of oxy-methyl-coumarilic acid $C_6H_3(OH)\left\langle\begin{matrix}CMe\\O\end{matrix}\right\rangle C.CO_2H$. White needles. Sol. benzene and hot water, v. e. sol. alcohol and ether. Dissolves in alkalis without alteration. Sparingly volatile with steam. Sublimes slowly at the ordinary temperature. Gives a violet colouration on warming with conc. H_2SO_4 (Hantzsch, *B.* 19, 2929).

Coumarone-*α*-carboxylic acids are identical with Coumarilic acids (*q. v.*).

o-**COUMARYL-ALCOHOL.** *Glucoside.* $C_6H_4(OC_6H_{11}O_5).C_2H_2.CH_2OH$. *Gluco-coumaryl alcohol.* [115°]. Fine white needles (containing aq). V. sol. alcohol, insol. ether. Formed by reduction of gluco-*o*-coumaric - aldehyde with sodium amalgam. By emulsin it is split up into coumaryl alcohol (which is an oil) and glucose (Tiemann a. Kees, *B.* 18, 1962).

CREATINE $C_4H_9N_3O_2$ *i.e.* $NH_2.C(NH).NMe.CH_2.CO_2H$. Mol. w. 131. *Methyl-guanido-acetic acid.* S.G. 1·35. S. 1·3 at 18°. S. (alcohol) ·016.

Occurrence.—In the muscular flesh of mammalia, birds, amphibia, and fishes (Chevreul, *J. Ph.* 21, 234; Pettenkofer, *A.* 52, 97; Liebig, *A.* 62, 282; 108, 354; Heintz, *P.* 62, 602; 70, 460; 73, 596; 74, 125; *C. R.* 24, 500; Gregory, *C. J.* 1, 25; Dessaignes, *C. R.* 38, 839; 41, 1258; *J. Ph.* [3] 32, 41; *A.* 97, 339; Schlossberger, *A.* 49, 344; 66, 80; Price, *C. J.* 3, 229; Städeler, *J. pr.* 72, 256). Occurs also in urine, blood, and brains (Verdeil a. Marcet, *J. Ph.* [3] 20, 89; Müller, *A.* 103, 142; Voit, *J.* 1867, 791). In some cases where creatine has been found it may have been formed from pre-existent creatinin by the process of extraction. Creatinin does not, however, appear to exist in flesh (Neubauer, *Fr.* 2, 22; Nawrocki, *Fr.* 4, 330).

Synthesis.—By the direct union of cyanamide with methyl-amido-acetic acid (sarcosine) in aqueous or alcoholic solution (Volhard, *Z.* [2] 5, 319; Strecker, *J.* 1868, 686).

Preparation.—Finely-chopped meat (250 g.) is heated with water (250 c.c.) at 60° for 10 minutes, the liquid is squeezed out and heated till the albumen is coagulated. The filtrate is treated with lead sub-acetate as long as ppn. occurs, is filtered, and freed from excess of lead by H_2S. The filtrate from PbS is evaporated to a syrup, from which creatine slowly separates; a further quantity may be ppd. by adding alcohol (2 or 3 vols.) (Neubauer, *Fr.* 2, 22; Mulder a. Monthaan, *Z.* [2] 5, 341).

Properties.—Monoclinic prisms (containing aq). Sl. sol. water, v. sl. sol. alcohol, insol. ether. The aqueous solution is neutral to litmus. Converted into its anhydride creatinin by heating with aqueous HCl, with $ZnCl_2$, with H_2SO_4, or even (although slowly) with water at 100°. Gaseous HCl passed over creatine at 100° also forms creatinin hydrochloride. If 5 or 6 drops of a 20 p.c. solution of $AgNO_3$ are added to 2 c.c. of a cold saturated solution of creatine, and a solution of KOH is added so as just to redissolve the white pp. which is first formed, the liquid presently solidifies to a transparent jelly; reduction of silver takes place on heating (Engel, *C. R.* 78, 1707).

Reactions.—1. Boiling *baryta-water* splits it up into urea (or CO_2 and NH_3) and methyl-amido-acetic acid. Methyl-hydantoïn is also formed.—2. *Nitrous acid* decomposes it, giving off half its nitrogen in the free state.—3. Alkaline NaOBr gives off two-thirds of the nitrogen as such (Hüfner, *J. pr.* [2] 1, 7).—4. Boiling with water and HgO gives methyl-guanidine and oxalic acid.—5. When heated with soda-lime it gives off methylamine.

Salts.—$B'_2H_2SO_4$: slender prisms.—B'HCl.—$B'HNO_3$: short thick prisms.—$B'CdCl_2$ 2aq: large crystals.—$B'ZnCl_2$: small crystals, resolved by hot water into creatine and $ZnCl_2$ (Neubauer, *A.* 137, 298).—$HgC_4H_7N_3O_2\,\frac{1}{2}$aq: white pp. from creatine, $HgCl_2$, and KOH (Engel, *C. R.* 80, 885; *B.* 8, 546).

Amphicreatine $C_9H_{19}N_7O_4$. A base occurring in muscular tissue (Gautier, *Bl.* [2] 48, 19). Yellow crystals; not ppd. by $Cu(OAc)_2$ or $HgCl_2$ but ppd. by sodium phosphomolybdate. Its **hydrochloride** is crystalline but not deliquescent. Its **platinochloride** forms soluble tables.

Isomeride of creatine *v.* ALACREATINE, vol. i. p. 93.

CREATININE $C_4H_7N_3O$ *i.e.*

$$HN{:}C\begin{matrix}\diagup NMe\cdot CH_2\\ \qquad\qquad |\\ \diagdown NH\,.\,CO\end{matrix}$$

. Mol. w. 113. S. 9 at 16°. S. (alcohol) 1 at 16° (Liebig); ·3 at 16° (Johnson).

Occurrence.—In human urine to the extent of ·5 p.c. (Pettenkofer, *A.* 52, 97; Heintz, *P.* 62, 602; 73, 595; 74, 125; Liebig, *A.* 62, 298, 324; Neubauer, *A.* 119, 39). Occurs also in urine of horses, calves, and dogs (Heintz; Voit, *C. C.* 1867, 504; Socoloff, *A.* 78, 243; 80, 114; Maly, *A.* 159, 279) and in the flesh of some fish (Krukenberg, *J. Th.* 1881, 344).

Formation.—From creatine by the action of mineral acids or of dehydrating agents.

Preparation.—1. Fresh human urine is neutralised with milk of lime; chloride of calcium added as long as a pp. of phosphate of calcium continues to form; the filtrate evaporated till the salts crystallise out; 32 pts. of the mother-liquor mixed with 1 pt. of chloride of zinc dissolved in the smallest possible quantity of water; the mixture set aside for four days; and the zinc-compound, which separates in nodules, washed with cold water. The zinc-compound is then decomposed by boiling with $Pb(OH)_2$, the filtrate is evaporated, and the mixture of creatine and creatinine digested with cold absolute alcohol, which dissolves the creatinine only (Liebig; Dessaignes, *J. Ph.* [3] 32, 42; Heintz; Loebe, *J. pr.* 82, 170; *Rép. chim. pure*, 1861, 25; Neubauer, *A.* 119, 27; Socoloff, *A.* 78, 243; Grocco, *C. C.* 1887, 17).—2. From urine, after adding $\frac{1}{20}$ vol. saturated aqueous NaOAc, by fractional ppn. with $HgCl_2$. A spherical salt $(C_4H_7HgN_3OHCl)_2 3HgCl_2$ 2aq is obtained, which is suspended in water and decomposed by H_2S. The filtrate on evaporation deposits creatinine hydrochloride, whence $Pb(OH)_2$ liberates creatinine (Johnson, *Pr.* 42, 365; 43, 493).

Properties.—Monoclinic prisms (anhydrous) or efflorescent prisms (containing 2 aq). Neutral to litmus (Salkowski, *H.* 12, 211). V. sol. hot water, m. sol. hot alcohol. According to Johnson (*Pr.* 43, 493) there are two varieties of creatinine, differing in reducing power, solubility, and character of their gold salts. Each exists in efflorescent and in tabular form. 1 part of tabular creatinine from urine dissolves in 10·78 pts. water at 17°, and in 362 pts. alcohol at 17°, and its Pt salt dissolves in 14·1 pts. water at 15°; on the other hand, 1 pt. of tabular creatinine from creatine dissolves in 10·68 pts. water at 16·5°, and in 324 pts. alcohol at 18·5°, while its Pt salt requires 24·4 pts. water at 15°. According to Liebig, 1 pt. creatinine dissolves in 11·5 pts. water at 16°, and in 102 pts. alcohol at 16°.

Reactions.—1. In alkaline solutions it is slowly converted by taking up water into creatine (Dessaignes, *J. Ph.* [3] 32, 41).—2. Boiling with water and HgO gives methyl-guanidine.—3. *Baryta-water* at 100° gives NH_3, and methyl-hydantoïn (Neubauer, *A.* 137, 289).—4. $KMnO_4$ gives oxalic acid and methyl-guanidine.

Detection.—1. A small quantity of Fehling's solution at 60° gives a white flocculent pp., consisting of a compound of creatinine with cuprous oxide. 1 mol. creatinine can reduce about $\frac{3}{4}$ mol. CuO (Worm-Müller, *J. Th.* 1881, 76; Maschke, *Fr.* 17, 134). According to Johnson (*Pr.* 42, 365; 43, 493) the creatinine obtained from creatine has not the same reducing power as that from urine, the reducing effect of 2 mols. glucose being equal to that of 5 mols. of the former, but only 4 mols. of the latter.—2. If a dilute solution of sodium nitroprusside is added to a solution of creatinine and dilute NaOH slowly dropped in, a ruby-red colouration is produced. By this test the presence of creatinine in urine can be demonstrated. With creatine no colour is produced, unless it is previously converted into creatinine by boiling with a dilute acid; in this way the presence of creatine in milk can be proved (Weyl, *B.* 11, 2175). On acidifying and warming prussian blue is formed (Salkowski, *H.* 4, 133; Colasanti, *G.* 17, 129). According to Guareschi (*C. C.* 1887, 580) this reaction is given also by thio-hydantoïn, methyl-hydantoïn, and other compounds containing the group $N.CH_2.CO.N$.

Salts.—B'HCl: prisms (from alcohol) or laminæ (from water).—$B'HAuCl_4$. According to Johnson this salt when prepared from creatinine derived from creatine is decomposed by ether, but when prepared from urinary creatinine it is not affected by ether.—$B'_2H_2PtCl_6$ 2aq: orange prisms. Solubility: *v. supra.*—B'HI: large crystals (from water).—$B'_2H_2SO_4$: dimetric tables (from dilute alcohol).—B'_2ZnCl_2: monoclinic prisms (Schmidt, *A.* 61, 332). Insol. absolute alcohol. S. 1·86 at 15°; 3·65 at 100°. S. (98 p.c. alcohol) ·0108 at c. 18°; S. (87 p.c. alcohol) ·0174 (Neubauer).—$B'_2H_2ZnCl_4$: large crystals, v. sol. water and alcohol (Dessaignes, *J. Ph.* [3] 32, 43). NaOAc added to its solution pps. B'_2ZnCl_2 (Neubauer, *A.* 120, 267).—B'_2CdCl_2: more soluble in water than B'_2ZnCl_2.—$B'_2Hg(NO_3)_2HgO$: crystalline pp. formed by adding aqueous mercuric nitrate to a conc. solution of creatinine.—$(B'AgNO_3)_2Ag_2O$: delicate white needles (from water).

(α)-**Nitroso-creatinine** (?) $C_4H_8N_4O_2$. [210°]. Formed, together with its isomeride, by passing nitrous acid gas into a conc. solution of creatinine. It is much less soluble in water than its (β)-isomeride (Dessaignes, *C. R.* 41, 1258; *A.* 97, 339; Märcker, *A.* 133, 305). Crystalline powder, sl. sol. cold water, v. sl. sol. alcohol. HCl at 100° converts it into methyl-parabanic acid, NH_3, and oxalic acid (Strecker, *A.* 118, 151). Br forms $C_4H_7BrN_4O_2$ (?), a neutral crystalline substance, v. sol. water. EtI at 160° followed by Ag_2O gives extremely soluble needles of $C_4H_9NO_4$ [152°]. Salts. — B'HCl aq. — $B'_2H_2PtCl_6$. — $B'HNO_3$.

(β)-**Nitroso-creatinine** $C_4H_8N_4O_2$. [195°]. Formed as above. Nodules, v. sol. water. Salts.—B'HCl: laminæ, v. e. sol. cold water.—$B'_2H_2PtCl_6$.

Ethyl-creatinine $C_4H_6EtN_3O$. From creatinine and EtI at 100°, the resulting hydroiodide being decomposed by moist Ag_2O (Neubauer, *A.* 119, 50; 120, 257). Needles (containing ½aq). V. e. sol. alcohol, insol. ether.—B'HCl: needles, v. e. sol. alcohol and water, insol. ether.—$B'_2H_2PtCl_6$.—B'HI: needles.

Xantho-creatinine $C_6H_{10}N_4O$.

Occurrence.—In muscular tissue (Gautier, *Bl.* [2] 48, 18) and in human urine, especially during fatigue (Monari, *G.* 16, 538).

Properties.—Sulphur-coloured crystals, having a slightly bitter taste. On warming it smells like acetamide. It has a double action on litmus, turning blue litmus red, and sensibly blueing red litmus.

Reactions.—$ZnCl_2$ gives a similar pp. to creatine, B'_2ZnCl_2. $AgNO_3$, a flocculent pp., sol. hot water, crystallising in needles. Ppd. after some time by sodium phosphomolybdate. Its hydrochloride forms feathery crystals; its platinochloride crystallises in long soluble bundles.

Chrusocreatinine *v.* p. 171.

CRENIC ACID (κρήνη). Said by Berzelius (*P.* 13, 84; 29, 3, 238) to occur in vegetable mould and in the ochreous deposits of ferruginous waters. The deposit is boiled with potash, and the filtrate treated with HOAc and cupric acetate as long as a dark-brown pp. continues to form. This pp. contains apocrenic acid. The filtrate is neutralised with ammonium carbonate, more cupric acetate is added, and the liquid heated to 80°; cupric crenate is then ppd. Crenic acid is pale yellow and uncrystallisable; apocrenic acid is brown and sl. sol. water. According to Mulder (*A.* 36, 243) crenic acid is $C_{12}H_{12}O_8$, while apocrenic acid is $C_{24}H_{12}O_{12}$. Crenic acid dissolves ferrous carbonate (Boutigny, *C. R.* 58, 247).

CREOSOL $C_8H_{10}O_2$ *i.e.* $C_6H_3Me(OMe)(OH)$ [1:3:4]. Mol. w. 138. (220°). S.G. $\frac{13}{}$ 1·0894. Occurs among the products of the distillation of beech wood and of gum guaiacum (Hlasiwetz, *A.* 106, 339). Formed also by distilling homovanillic acid $C_6H_3(OMe)(OH).CH_2.CO_2H$ with lime (Tiemann a. Nagai, *B.* 10, 206). Aromatic liquid, sl. sol. water, miscible with alcohol, ether, and benzene. Fe_2Cl_6 gives a green colour. HI or potash-fusion convert it into $C_6H_3Me(OH)_2$ (Tiemann a. Koppe, *B.* 14, 2025). PCl_5 gives $C_6H_3Me(OMe)Cl$ (?) (185°) S.G. 1·028 which gives a green colour with Fe_2Cl_6 and a pp. of AgCl with $AgNO_3$ (Biechele, *A.* 151, 115).

Salts. – $KC_8H_9O_2$ 2aq: needles, v. sol. water and alcohol.—KHA'_2 aq: thin prisms; decomposed by water into KA' and creosol.—BaA'_2 3aq: small scales.

Methyl ether $C_6H_3Me(OMe)_2$. (218°). Occurs in beech wood creosote (Tiemann a. Mendelsohn, *B.* 8, 1137). Formed by fusing papaverine with KOH (Goldschmiedt, *M.* 4, 705). Also from creosol, KOH, and MeI. Gives no colour with Fe_2Cl_6.

Ethyl ether $C_6H_3Me(OMe)(OEt)$. Oil.

Acetyl derivative $C_6H_3Me(OMe)(OAc)$. (247°). Oil (Tiemann, *B.* 9, 418; 10, 58).

CREOSOL SULPHONIC ACID $C_6H_2Me(OMe)(OH)(SO_3H)$. From creosol and conc. H_2SO_4 at 60° (Biechele, *A.* 151, 109; Tiemann a. Koppe, *B.* 14, 2026). Hygroscopic syrup.—KA': needles; its aqueous solution is coloured blue by Fe_2Cl_6.—BaA'_2.—PbA'_2.

CREOSOL CARBOXYLIC ACID *v. Methyl derivative* of DI-OXY-TOLUIC ACID.

CREOSOTE (κρέας σώζειν).—A mixture of substances of a phenolic character, which may be extracted by alkalis from the tar obtained by the dry distillation of wood. Rhenish beech tar creosote contains phenol, cresols, guaiacol, phlorol, and creosol (Reichenbach, *Schw. J.* 66, 301, 345; 67, 1, 57; 68, 352; Ettling, *A.* 6, 209; Laurent, *C.R.* 11, 124; 19, 574; Deville, *A. Ch.* [3] 12, 228; Gorup-Besanez, *A.* 78, 231; 86, 223; 143, 129; *Z.* [2] 4, 393; Voelckel, *A.* 86, 93; 87, 306; Hlasiwetz, *A.* 106, 339; Simon, *P.* 32, 129; Hübschmann, *A.* 11, 40; Köne, *A.* 16, 68; Flückiger, *Ph.* [3] 2, 1008; Ruot, *Bl.* [2] 8, 875; H. Müller, *Z.* 1864, 40; Marasse, *B.* 1, 99; 3, 71; *Z.* [2] 4, 502; 5, 348; Frisch, *J. pr.* 100, 223; J. Williams, *C. C.* 1873, 167; Hofmann, *B.* 8, 66; Tiemann a. Mendelsohn, *B.* 8, 1136; Clark, *Ph.* [3] 3, 1037; Wätzel, *Ar. Ph.* [3] 10, 180).

CRESAURIN *v. Anhydride of* TRI-OXY-TRI-TOLYL-CARBINOL.

CRESOLS C_7H_8O *i.e.* $C_6H_4Me(OH)$. Mol. w. 108. *Oxy-toluenes. Methyl phenols.*—The three cresols occur in the tar obtained by the destructive distillation of coal, beech wood, and pine wood (Schotten a. Tiemann, *B.* 11, 783; Schulze, *B.* 20, 410; Duclos, *A.* 109, 136; Marasse, *A.* 152, 64). They are best obtained in a state of purity from the corresponding toluidines by the diazo- reaction, or from the toluene sulphonic acids by potash-fusion. A cresol is formed by oxidising toluene in presence of Al_2Cl_6 (Friedel a. Crafts, *C. R.* 86, 884). Acid sulphates of the three cresols occur in horse's urine, and cresols are converted into such acids when given to animals in their food (Baumann a. Herter, *B.* 9, 1389). The three cresols, by heating with ammoniacal $ZnBr_2$ and NH_4Br, or with ammoniacal $ZnCl_2$ and NH_4Cl, are converted into the corresponding toluidines and di-tolyl-amines in variable proportion (Merz a. Müller, *B.* 20, 544).

Azo- compounds of the three cresols.—*p*-Cresol combines with diazo- compounds as easily as phenols not substituted in the *p*-position, the diazo- residue entering the *o*-position to the OH. Disazo- compounds of *p*-cresol cannot be obtained. In the azo- compounds of *o*- and *m*-cresol the diazo- residue takes the *p*- position to the OH. Both readily yield disazo- compounds, in which the two azo- residues stand in the *p*- and *o*- position to the hydroxyl, and hence are *meta* to each other. *o*- and *m*-Cresol readily give nitroso-derivatives, but *p*-cresol does not (Nölting a. Kohn, *B* 17, 351).

***o*-Cresol** $C_6H_4Me(OH)[2:1]$. [30°]. (190·8°). S.G. $\frac{65\cdot6}{}$ 1·0053; $\frac{0}{0}$ 1·0578. C.E. (0°–10°) ·00072 (Pinette, *A.* 243, 37). H. F. 50,992 (liquid); –3250 (solid) (Stohmann, *J. pr.* [2] 34, 311).

Formation.—1. By fusing toluene *o*-sulphonic acid with KOH (Engelhardt a. Latschinoff, *Z.* 1869, 620).—2. From *o*-toluidine.—3. By distilling (1, 2, *x*)-oxy-toluic acids with lime.—4. By heating carvacrol with P_2O_5, and fusing the resulting *o*-tolyl phosphate with KOH (Kekulé, *B.* 7, 1006).—5. By treating camphor with $ZnCl_2$ (Reuter, *B.* 16, 624).

Properties.—Crystalline. Converted by potash-fusion into salicylic acid. $KClO_3$ and HCl give di- and tri- chlorotoluquinone (Southworth, *A.* 168, 273). Br gives $C_6H_2Br_2Me(OH)$ [57°] (Werner, *Bl.* [2] 46, 278). Excess of Br gives $C_6H_2Br_3(OBr)$.

Salt.—$(C_6H_4MeO)_3Al$. From *o*-cresol, Al, and a little iodine (Gladstone a. Tribe, *C. J.* 49, 26). Black, vitreous mass, forming a dark-green solution in benzene, decomposed by water and by alcohol. On distillation it yields di-*o*-tolyl oxide $(C_6H_4Me)_2O$ (c. 275°), *o*-cresol, and a compound $C_{13}H_{14}O$, crystallising in colourless plates.

Benzoyl derivative C_7H_7OBz. Oil.

Methyl ether $C_6H_4Me(OMe)$. (171·3°). S.G. $\frac{0}{0}$ ·9957. S.V. 146·1. C.E. (0°–10°) ·00084 (Pinette, *A.* 243, 37; *cf.* Körner, *Z.* [2] 4, 327).

Ethyl ether $C_6H_4Me(OEt)$. (184·8°). S.G. $\frac{0}{0}$ ·9679. S.V. 170·9. C.E. (0°–10°) ·0009 (Pinette, *A.* 243, 38). From alcohol, EtBr and potassium cresol by boiling (Staedel, *A.* 217, 41). The yield is 67 p.c. Also from diazo-toluene sulphate and absolute alcohol (Remsen a. Orndorff, *Am.* 9, 394). HNO_3 converts it into $C_6H_2(NO_2)_2Me(OEt)$ [51°] and a little $C_6H_2(NO_2)_2Me(OH)$ [82°].

Ethylene ether $(C_7H_7O)_2C_2H_4$. [79°]. White plates, sl. sol. cold alcohol.

Propyl ether $C_6H_4Me(OPr)$. (204·1°). S.G. $\frac{0}{0}$ ·9517. S.V. 195. C.E. (0°–10°) ·00087 (Pinette).

Butyl ether $C_6H_4Me(OC_4H_9)$. (223°). S.G. $\frac{0}{0}$ ·9437. S.V. 218·4. C.E. (0°–10°) ·00092.

Heptyl ether $C_6H_4Me(OC_7H_{15})$. (277·5°). S.G. $\frac{0}{0}$ ·9243. S.V. 292·95. C.E. (0°–10°) ·00083.

Octyl ether $C_6H_4Me(OC_8H_{17})$. (292·9°). S.G. ·9231. S.V. 317·9. C.E. (0°–10°) ·00084.

Benzyl ether v. vol. i. p. 490.

***m*-Cresol** $C_6H_4Me(OH)$. [4°]. (202·8°). S.G. $\frac{0}{0}$ 1·0498. S.V. 123·2. C.E. (0°–10°) ·00078 (Pinette, *A.* 243, 40). μ_A 1·5316 at 25°. H.F. 53,044 (Stohmann, *J. pr.* [2] 34, 311). Occurs in coal-tar cresol, together with its *m*- and *p*-isomerides (Schulze, *B.* 20, 409; *cf.* Ihle, *J. pr.* [2] 14, 442). From thymol (100 g.) and P_2O_5 (40 g.); propylene being given off; the resulting *m*-tolyl-phosphoric acid being fused with KOH. The yield is 51 p.c. (Staedel, *A.* 217, 46; *cf.* Engelhardt a. Latschinoff, *Z.* 1869, 621; Southworth, *A.* 168, 268; Tiemann a. Schotten, *B.* 11, 769). Formed also by distilling *m*-oxy-uvitic acid with lime (Oppenheim a. Pfaff, *B.* 8, 886), and by distilling aluminium thymol (Gladstone a. Tribe, *C. J.* 41, 12). Formed also by the action of dry oxygen upon toluene in presence of Al_2Cl_6 (Friedel a. Crafts, *A. Ch.* [6] 14, 436).

Properties.—Liquid. Can be solidified by throwing a crystal of phenol into the liquid cooled in a freezing-mixture (Staedel, *B.* 18, 3443). Its aqueous solution is coloured bluish-violet by Fe_2Cl_6. Fusion with KOH gives *m*-oxy-benzoic acid. HCl and $KClO_3$ from di-chloro-toluquinone Br (3 mols.) gives $C_6HBr_3Me(OH)$ [82°]; excess of Br forms $C_6HBr_3Me(OBr)$ which liberates iodine from KI (Werner, *Bl.* [2] 46, 276).

Benzoyl derivative C_7H_7OBz. [38°]. (c. 295°).

Methyl ether $C_6H_4Me.(OMe)$. (177·2°) S.G. $\frac{0}{0}$ ·9891. S.V. 147·45. C.E. (0–10°) ·00092 (Pinette, *A.* 243, 40). H.F.p. 39,748 (C,O_2 = 94; H_2O = 69) (Stohmann, *J. pr.* [2] 35, 24).

Ethyl ether $C_6H_4Me(OEt)$. (192°). S.G. $\frac{0}{0}$ ·965. S.V. 172. C.E. (0°–10°) ·0009 (Pinette, *A.* 243, 41). From *m*-diazo-toluene sulphate and alcohol (Remsen a. Orndorff, *Am.* 9, 394).

Propyl ether $C_6H_4Me(OPr)$. (210·6°). S.G. $\frac{0}{0}$ ·9484. S.V. 196·2. C.E. (0°–10°) ·0009.

Butyl ether $C_6H_4Me(OC_4H_9)$. (229·2°). S.G. $\frac{0}{0}$ ·9407. S.V. 220·45. C.E. (0°–10°) ·00092.

Heptyl ether $C_6H_4Me(OC_7H_{15})$. (283·2°). S.G. $\frac{0}{0}$ ·9202. S.V. 296·7. C.E. (0°–10°) ·00084.

Octyl ether $C_6H_4Me(OC_8H_{17})$. (298·9°). S.G. $\frac{0}{0}$ ·9194. S.V. 321·95. C.E. (0°–10°) ·00086 (Pinette, *A.* 243, 43).

Benzyl ether v. vol. i. p. 490.

m-Cresyl ether v. DI-*m*-TOLYL OXIDE.

***p*-Cresol** $C_6H_4Me(OH)$. [36°]. (201·8°). S.G. $\frac{65\cdot6}{}$ ·9962; $\frac{0}{0}$ 1·0522. S.V. 123·45. C.E. (0°–10°)

·00086 (Pinette, *A.* 243, 43). H.F. 51,100 (solid); −2459 (liquid) (Stohmann, *J. pr.* [2] 34, 311).

Occurrence.—In coal-tar (H. Buff, *B.* 4, 378). As *p*-tolyl sulphuric acid in urine of horses, of cows, and sometimes of men (Brieger, *H.* 4, 204).

Formation.—1. By fusing its sulphonate with KOH (Wurtz, *A.* 144, 121; 156, 258). If the mixture of sulphonic acids of crude cresol is treated with excess of baryta, basic barium *p*-cresol-sulphonate is ppd. (Armstrong a. Field, *C. N.* 29, 282; Baumann, *H.* 6, 185).—2. From *p*-toluidine.—3. Got by putrefaction of ox-brain at 40° (F. Stöckly, *J. pr.* [2] 24, 17). Found also among the products of putrefaction of horses' liver, tyrosine, *p*-oxy-phenyl-acetic acid, and *p*-oxy-phenyl-propionic acid (Baumann a. Brieger, *H.* 3, 149; 4, 304; Weyl, *H.* 3, 312).—4. Together with carpene by the dry distillation of podocarpic acid or its Ca salt (Oudemans, *A.* 170, 259).—5. By heating *p*-oxy-phenyl-acetic acid with CaO (Salkowski, *B.* 12, 1440).

Preparation.—From *p*-toluidine by diazotisation in presence of excess of H_2SO_4.

Properties.—Prisms. Its aqueous solution is coloured blue by Fe_2Cl_6. Potash-fusion converts it into *p*-oxy-benzoic acid. HCl and $KClO_3$ give no chlorinated toluquinone (Southworth, *A.* 168, 271). Br (2 mols.) gives a pp. of $C_6H_2Br_2Me(OH)$ [49°], but a larger quantity of Br (3 mols.) gives $C_6H_2Br_2Me(OBr)$, while a large excess forms $C_6H_2Br_3(OH)$ (Werner, *Bl.* [2] 46, 278). Chloral forms $C_7H_8OC_2HCl_3O$ [52°–56°] (Mazzara, *G.* 13, 272).

Salt.—$(C_6H_4MeO)_3Al$. On distillation it gives a small quantity of di-*p*-tolyl oxide and a ketone $C_{15}H_{11}O$ [168°] (307°). S. (alcohol) ·4 at 20°; 2·5 at 78°. S. (benzene) 3·3 at 21°. V.D. 209·1 (Gladstone, *C. J.* 41, 8).

Acetyl derivative C_7H_7OAc. (c. 210°). Oil (Fuchs, *B.* 2, 626).

Benzoyl derivative C_7H_7OBz. [70·6°]. H.F. 69,010 (Stohmann, *J. pr.* [2] 36, 8; *cf.* Guareschi, *A.* 171, 142).

Lauryl derivative $C_7H_7O.C_{12}H_{23}O$. [28°]. (220°) at 15 mm. (Kraft a. Bürger, *B.* 17, 1378).

Myristyl derivative $C_7H_7O.C_{14}H_{27}O$. [39°]. (240°) at 15 mm. (K. a. B.).

Palmityl derivative $C_7H_7O.C_{16}H_{31}O$. [47°]. (258°) at 15 mm.

Stearyl derivative $C_7H_7O.C_{18}H_{35}O$. [54°]. (276°) at 15 mm. (K. a. B.).

Methyl ether $C_6H_4Me(OMe)$. (175°). S.G. $\frac{0}{0}$ ·9868. S.V. 147·7. C.E. (0–10°) ·00084 (Pinette, *A.* 243, 44; Körner, *Bull. Acad. Belg.* [2] 24, 154).

Ethyl ether $C_6H_4Me(OEt)$. (189·9°). S.G. $\frac{0}{0}$ ·9662. S.V. 172·1. C.E. (0°–10°) ·00086 (Pinette, *A.* 243, 44). H.F.p. 46,880 (Stohmann, *J. pr.* [2] 35, 24). Formed (11½ p.c.), together with aldehyde and toluene (18 p.c.), by decomposing *p*-diazo-toluene sulphate with alcohol (Remsen a. Orndorff, *Am.* 9, 394). HNO_3 (S.G. 1·5) converts it into di-nitro-*p*-cresol [84°] and its ether [75°] (Staedel, *B.* 14, 898). $K_2Cr_2O_7$ and HOAc form [4:1] $C_6H_4(OEt)CO_2H$.

Ethylene ether $(C_6H_4MeO)_2C_2H_4$. [135°]. (297°) (Fuchs, *B.* 2, 621).

Propyl ether $C_6H_4Me(OPr)$. (210·4°). S.G. $\frac{0}{0}$ ·9497. S.V. 196. C.E. (0°–10°) ·00089 (Pinette, *A.* 243, 45).

Butyl ether $C_6H_4Me(OC_4H_9)$. (229·5°). S.G. $\frac{0}{0}$ ·9419. S.V. 220·8. C.E. (0°–10°) ·00092.

Heptyl ether $C_6H_4Me(OC_7H_{15})$. (283·3°). S.G. $\frac{0}{0}$ ·9228. S.V. 297·7. C.E. (0°–10°) ·0009.

Octyl ether $C_6H_4Me(OC_8H_{17})$. (298°). S.G. $\frac{0}{0}$ ·9199. S.V. 322·4. C.E. (0°–10°) ·00088.

Benzyl ether v. vol. i. p. 490.

Nitro-benzyl ether v. p-Tolyl nitro-benzyl oxide.

p-Cresyl ether v. Di-*p*-tolyl oxide.

Derivatives of cresols *v.* Amido-cresol, Bromo-cresol, Chloro-cresol, Iodo-cresol, Nitro-cresol.

CRESOL DICARBOXYLIC ACIDS *v.* Oxy-uvitic, Oxy-methyl-iso-phthalic, and Oxy-methyl-terephthalic acids.

o*-CRESOL-PHTHALEIN** $C_{22}H_{18}O_4$ ***i.e.

$(C_6H_4MeOH)_2C{<}\begin{smallmatrix}C_6H_4\\O\end{smallmatrix}{>}CO$. [214°].

Preparation.—By heating *o*-cresol (2 pts.), phthalic anhydride (3 pts.), and stannic chloride (2 pts.) at 120°–125°. From the fused mass thus obtained the undecomposed cresol is separated by steam-distillation; and the phthalein is purified by recrystallisation from alcohol (Baeyer a. Fraude, *A.* 202, 153).

Properties.—Flesh-red crystals, v. sol. alcohol and ether, m. sol. hot water; sol. caustic alkalis with violet colouration, showing a broad absorption band in the red.

Reactions.—1. With *bromine* it forms a di-bromo-derivative together with a bromo-oxy-toluyl-benzoic acid $CO_2H.C_6H_4.CO.C_6H_2MeBr(OH)$ [228°].—2. With *nitric acid* it gives a di-nitro-derivative.—3. *Zinc-dust* forms the corresponding phthalin.—4. *Phthalic anhydride* and *conc. sulphuric acid* give oxy-methyl-anthraquinone.

Di-acetyl derivative $C_{22}H_{16}Ac_2O_4$. [75°]: white amorphous mass.

Di-benzoyl derivative $C_{22}H_{16}Bz_2O_4$. [196°].

Di-bromo-derivative $C_{22}H_{16}Br_2O_4$. [255°]. Crystalline. Sol. alkalis with blue, and in conc. sulphuric acid with rose-red, colouration. Converted by phthalic anhydride and sulphuric acid to bromo-oxy-methyl-anthraquinone.

Di-nitro- derivative $C_{22}H_{16}(NO_2)_2O_4$ [248°]: yellow crystals. Sol. Na_2CO_3Aq with red-brown colouration.

o-Cresol-phthalin $C_{22}H_{20}O_4$ *i.e.* $(C_6H_3Me.OH)_2CH.C_6H_4.CO_2H$. [218°]. Prepared by reduction of *o*-cresol phthaleïn with zinc-dust and KOH (Fraude, *A.* 202, 168; *B.* 12, 243). Small concentrically grouped needles; sol. water and alcohol, slowly oxidised to *o*-cresol-phthaleïn by exposure to air. By the action of H_2SO_4 it gives *o*-cresol phthalidin.

Di-acetyl derivative $C_{20}H_{18}Ac_2O_4$. [139°]. Crystalline powder. Sol. acetone. Converted by conc. H_2SO_4 into the phthalidin.

Di-bromo-derivative $C_{20}H_{18}Br_2O_4$. [236°].

p-Cresol-phthaleïn anhydride $C_{22}H_{16}O_3$ *i.e.*

$O{<}\begin{smallmatrix}C_6H_3Me\\C_6H_3Me\end{smallmatrix}{>}C{<}\begin{smallmatrix}C_6H_4\\O\end{smallmatrix}{>}CO$. [246°]. From *p*-cresol, phthalic anhydride and H_2SO_4 at 160°. Excess of *p*-cresol is removed by steam, and the residue washed with boiling dilute KHO (Drewsen, *A.* 212, 340). Plates or prisms (from alcohol). Sol. alcohol, ether, and benzene; v. sol. $CHCl_3$; insol. ligroïn, KHO and weak acids. Conc. H_2SO_4 gives a green fluorescence. Sublimes unchanged. **Reduced by zinc-dust and AcOH to the phthalin anhydride. Fused with KHO it yields di-oxy-di-methyl benzophenone.** [105°]. Heating with conc. H_2SO_4 yields methyl-*erythro*-oxy-anthraquinone.

p-**Cresol phthalin anhydride** $C_{22}H_{18}O_3$ *i.e.*

$$O\left<\begin{matrix}C_6H_3Me\\C_6H_3Me\end{matrix}\right>CH.C_6H_4.CO_2H.$$

[210°]. From the preceding by reduction with zinc-dust and AcOH; crystallises from $CHCl_3$. V. sol. alcohol, benzene, ether, and acetic acid. Sol. conc. H_2SO_4 forming a brown solution (Drewsen, *A.* 212, 340).

o-**CRESOL SULPHONIC ACID** $C_7H_8SO_4$ *i.e.* $C_6H_3Me(OH)(SO_3H)$ [1:2:4]. From *o*-toluidine sulphonic acid by displacing NH_2 by OH through the diazo- reaction (Hayduck, *A.* 172, 204; 174, 345). Formed also in small quantity by sulphonating *o*-cresol in the cold. At high temperatures it is the only product of this sulphonation (Engelhardt a. Latschinoff, *Z.* 1869, 621; Hantke, *B.* 20, 3209). Does not crystallise. Potash-fusion converts it into salicylic acid, together with small quantities of (1,2,4)-di-oxy-benzoic acid.

Salts.—$BaA'_2 1\frac{1}{2}$aq: extremely soluble aggregates of monoclinic prisms (Hayduck).—BaA'_2aq (E. a. L.).—BaA'_2: amorphous (Hantke).—$KA' \frac{1}{2}$aq: short needles (from dilute alcohol).

Methyl derivative $C_6H_3Me(OMe)(SO_3H)$. Formed by boiling *o*-diazo-toluene sulphonic acid with MeOH. Syrup.—BaA'_2 2aq: small laminæ.

Ethyl derivative $C_6H_3Me(OEt)SO_3H$. Formed by boiling *p*-diazo-toluene sulphonic acid with alcohol (Paysan, *A.* 221, 214, 363; Hayduck, *A.* 172, 215).—KA'aq.—BaA'_2 2aq (P.).—$BaA'_2$3aq (H.).—$PbA'_2$3aq. The **amide** $C_6H_3Me(OEt).SO_2NH_2$ crystallises in laminæ [137°]; the **chloride** is an oil.

o-**Cresol sulphonic acid** $C_6H_3Me(OH).SO_3H$ [1:2:5]. From the corresponding toluidine sulphonic acid by boiling the diazo- salt with water (Nevile a. Winther, *C. J.* 37, 631). The chief product of the sulphonation of *o*-cresol in the cold (Hantke, *B.* 20, 3209). Very deliquescent needles.

Reactions.—1. At 140° it is split up by water into *o*-cresol and H_2SO_4.—2. HNO_3 (1 part) with water (2 or 3 parts) converts it into di-nitro-*o*-cresol, [86°].—3. Potash-fusion gives salicylic acid and very small quantities of a di-oxy-benzoic acid which is turned blue by Fe_2Cl_6.

Salts.—$BaA'_2 2\frac{1}{2}$aq (Gerver, *A.* 169, 386). Needles (from dilute alcohol). Gives a violet colour with Fe_2Cl_6.—BaA'_2: large sparingly soluble plates (Hantke).—KA': very soluble pearly plates (H.).—$CuA'_2$5aq: tables.—$PbA'_2 2\frac{1}{2}$aq (G.). Small needles.

Ethyl derivative $C_6H_3Me(OEt)(SO_3H)$ [1:2:5].—From $C_6H_3Me(NH_2)SO_3H$, by heating its diazo- derivative with alcohol (Foth, *A.* 230, 306).—$BaA'_2$4aq.

m-**Cresol sulphonic acid** $C_6H_3Me(OH)(SO_3H)$ [1:3:6]. [118°]. From *m*-cresol and H_2SO_4 at 110° (Claus a. Krauss, *B.* 20, 3089; *cf.* Engelhardt a. Latschinoff, *Z.* 1869, 622; Nölting a. Salis, *B.* 15, 1862). Plates (containing 2aq) [75°] (from dilute H_2SO_4) or (containing $1\frac{1}{2}$aq) [96°] (from conc. H_2SO_4). V. sol. water, alcohol, ether, and benzene. Gives a violet colour with Fe_2Cl_6. CrO_3 gives toluquinone.—$KA' 2\frac{1}{2}$aq: stellate group of needles with fatty lustre.—$CuA'_2$3aq: tufts of pale-green prisms.—BaA'_2aq: nodules.—$BaC_7H_6SO_4$ 2aq.

p-**Cresol sulphonic acid** $C_6H_3Me(OH)(SO_3H)$ [1:4:2]. [188°]. From *p*-toluidine sulphonic acid by the diazo- reaction (Jenssen, *A.* 172, 237). Long needles (containing 5aq) [99°]. V. sol. water, alcohol, and ether. Hydrolysed by passing steam through its solution in dilute H_2SO_4 boiling above 120° (Armstrong a. Miller, *C. J.* 45, 148).—BaA'_2: amorphous, v. e. sol. water. Its solution is coloured violet by Fe_2Cl_6.

Methyl derivative $C_6H_3Me(OMe)SO_3H$. From the diazo- derivative of toluidine sulphonic acid by gently warming with methyl alcohol (Limpricht a. Heffter, *A.* 221, 352). Its **amide** crystallises in prisms [150°]; its **chloride** is an oil.—BaA'_2.—KA'.

Ethyl derivative $C_6H_3Me(OEt)(SO_3H)$. Prepared as above, using ethyl alcohol. Formed also by warming diazo-toluene sulphonic acid with alcohol (Remsen a. Palmer, *Am.* 8, 245).—$BaA'_2 3\frac{1}{2}$aq.—KA'. The **amide** $C_6H_3Me(OEt)SO_2NH_2$ [136°] (L. a. H.); [144°] (R. a. P.) crystallises in needles. The **chloride** is an oil.

p-**Cresol sulphonic acid** $C_6H_3Me(OH)(SO_3H)$ [1:4:3]. From *p*-cresol and fuming H_2SO_4. Also from the corresponding *p*-toluidine sulphonic acid by the diazo- reaction (Engelhardt a. Latschinoff, *Z.* 1869, 619; Pechmann, *A.* 173, 203). Syrup. Fe_2Cl_6 colours its solution blue. Potash-fusion gives *p*-oxy-benzoic acid.—KA'2aq: laminæ.—BaA'_2: tables. S. 7 at 17° (Baumann, *H.* 4, 313).—$BaC_7H_6SO_4$ 2aq. V. sl. sol. water.—$PbA'_2$3aq.—$PbA'_2 1\frac{1}{2}$aq: laminæ (from alcohol).

Cresol sulphonic acid $C_6H_3Me(OH)(SO_3H)$ [1:?2:*x*]. Formed by fusing toluene di-sulphonic acid with KOH (Brunner, *Sitz. W.* [2] 78, 665). Feathery groups of crystals (containing $\frac{1}{2}$aq at 100°) [81°]. Hygroscopic. V. sol. alcohol and ether.—$NaA'_2$2aq.—KA'2aq: prisms [c. 228°].—BaA'_2aq. Its solution is turned blue by Fe_2Cl_6.—$CaA'_2 1\frac{1}{2}$aq.—$PbA'_2$3aq.—$CuA'_2$8aq.—$ZnA'_2 10\frac{1}{2}$aq.

Cresol sulphonic acids have been obtained by sulphonating cresols by Duclos (*A.* 109, 138), and by Armstrong a. Field (*B.* 6, 974), but not sufficiently characterised.

p-**Cresol** *exo*-**sulphonic acid** $C_6H_4(OH).CH_2SO_3H$ [1:4]. From $C_6H_4(NH_2).CH_2SO_3H$ by diazo- reaction (Mohr, *A.* 221, 221). Deliquescent needles; v. sol. alcohol. The aqueous solution is turned bluish-violet by Fe_2Cl_6.—KA', $\frac{1}{2}$aq.—$BaA'_2 7\frac{1}{2}$aq.

Ethyl derivative $C_6H_4(OEt).CH_2.SO_3H$. Prepared by decomposing the diazo- derivative of $C_6H_4(NH_2).CH_2.SO_3H$ by boiling with alcohol.—BaA'_2 2aq.

o-**Cresol disulphonic acid** $C_6H_2Me(OH)(SO_3H)_2$ [1:2:3:5]. From *o*-toluidine disulphonic acid by diazo- reaction (Limpricht, *B.* 18, 2176; H. Hasse, *A.* 230, 293). Tables or needles. V. sol. water and alcohol.—$K_2A'' 1\frac{1}{2}$aq: very soluble needles.—$BaA'' 3\frac{1}{2}$aq: small needles.

Ethyl derivative $C_6H_2Me(OEt)(SO_3H)_2$. From the diazo- derivative of *o*-toluidine disulphonic acid by boiling with alcohol under an extra pressure of 400 mm.—$BaA'' 2\frac{1}{2}$aq.

m-**Cresol disulphonic acid** $C_6H_2Me(OH)(SO_3H)_2$. From *m*-cresol (1 pt.) and

H_2SO_4 (5 pts.) at 130° (Claus a. Krauss, *B.* 20, 3089). V. sol. water and alcohol, m. sol. ether and benzene.—KA′ 3aq : plates.—BaA′$_2$ ½aq.

p-**Cresol disulphonic acid** $C_6H_2Me(OH)(SO_3H)_2$ [1:4:3:2or6]. From *p*-toluidine di-sulphonic acid by diazo- reaction (Limpricht, *B.* 18, 2178; E. Richter, *A.* 230, 322). Needles. V. e. sol. water and alcohol.—BaA″ 4aq: needles.—K_2A″ ½aq ?: tables.—PbA″ 3aq : v. sol. water.

p-**Cresol disulphonic acid** $C_6H_2Me(OH)(SO_3H)_2$ [1:4:3:5]. From *p*-cresol sulphonic acid and fuming H_2SO_4 (Engelhardt a. Latschinoff, *Z.* 1869, 620).—K_2A″ 3aq : crystals, v. e. sol. water.—BaA″ 2½aq : needles, sl. sol. water.

m-**Cresol trisulphonic acid** $C_6HMe(OH)(SO_3H)_3$. From *m*-cresol, fuming H_2SO_4, and P_2O_5 at 180° (Claus a. Krauss, *B.* 20, 3089). The Ba salt is v. sol. water.

CRESORCELLIC ACID *v.* (5:3:2:1)-DI-OXY-*o*-TOLUIC ACID.

CRESORCIN *v.* DI-OXY-TOLUENE.

CRESORCIN-CARBOXYLIC ACID *v.* DI-OXY-TOLUIC ACID.

CRESOTIC ACID *v.* OXY-TOLUIC ACID.

CRESS OIL. The volatile oil of garden-cress (*Lepidium sativum*) consists to the extent of 75 p.c. of phenyl-acetonitrile (benzyl cyanide) (Hofmann, *B.* 7, 1293). The volatile oil of water-cress (*Nasturtium officinalis*) consists of phenyl-propionitrile (Hofmann, *B.* 7, 520).

CRESYL COMPOUNDS *v.* TOLYL COMPOUNDS.

CROCETIN $C_{34}H_{46}O_9$. Formed by the action of dilute acids on crocin, a sugar (crocose) being the correlative product (Kayser, *B.* 17, 2231). Red powder. V. sol. alcohol and ether, nearly insol. water. Dissolves in alkalis with a yellow colour. Like crocin it dissolves in H_2SO_4 with a blue colour, which slowly becomes violet, red, and finally brown. Stuffs mordanted with stannous chloride acquire, by boiling in a solution of crocetin (from Gardenia), a dingy greenish-yellow colour, which by treatment with ammoniacal water is converted into a brilliant yellow colour, unaltered by light and air. The yellow robes of the Chinese mandarins are dyed with the fruit of the *Gardenia*.

CROCIN (*the colouring matter of saffron*) $C_{40}H_{70}O_{28}$. Appears to be identical with the colouring matter of Chinese yellow pods (*Gardenia grandiflora*) (Rochleder, *J. pr.* 56, 68). Yellow powder. V. sol. water and dilute alcohol, sl. sol. absolute alcohol, nearly insol. ether.

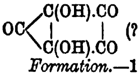
Preparation.—The saffron, which has been previously extracted with ether, is soaked in cold water, the colouring-matter is removed from the aqueous solution by animal charcoal, and after drying is extracted from the charcoal by means of 90 p.c. alcohol.

Reactions.—It dissolves in H_2SO_4 with a deep blue colour, which gradually becomes violet, then red, and finally brown. HNO_3 also produces a blue colouration, which almost instantaneously passes into brown. By dilute acids it is split up into crocetin $C_{34}H_{46}O_9$ and a sugar (crocose) $C_6H_{12}O_6$ (Kayser, *B.* 17, 2228).

CROCONAMIC ACID $C_5H_3NO_4$ *i.e.* $C_5O_3(OH)(NH_2)$, or more probably $C_5O_2(NH)(OH)_2$. *Imido-croconic acid.*—The ammonium salt is formed by heating the di-anilide of croconic acid with aqueous NH_3. Mono-basic acid.

Salts.—A′NH_4: red prisms with bluish reflex. A′Ag *x*aq : yellow needles.—A′$_2$Ba 3aq : sparingly soluble small yellow needles.—BaC_5HNO_4 4aq : sparingly soluble yellow plates (Nietzki a. Benckiser, *B.* 19, 773; 21, 1856).

CROCONIC ACID $C_5H_2O_5$ or



$$OC\begin{cases} C(OH).CO \\ \quad| \qquad\quad | \\ C(OH).CO \end{cases} (?).$$

Formation.—1. From the black-residues obtained in the preparation of potassium by Brunner's method (Gmelin, *P.* 4, 37; *A.* 37, 58; Liebig, *A.* 11, 182; *P.* 33, 90; Heller, *J. pr.* 12, 230; *A.* 24, 1; 34, 232; Will, *A.* 118, 177). When CO is passed over melted potassium and the product is treated with water, a red salt, **potassium rhodizonate**, is formed. A solution of this salt changes on standing exposed to air to potassium croconate. Excess of alkali converts rhodizonic acid into croconic acid dihydride, which appears to be an intermediate body in the formation of croconic acid from rhodizonic acid (Nietzki, *B.* 20, 1617).—2. By heating benzene-tri-quinone C_6O_6 to 100°, or by boiling it with water, CO_2 being evolved.—3. By exposing an alkaline solution of tetra-oxy-quinone $C_6(OH)_4O_2$ to the air, oxalic acid being formed simultaneously.—4. By evaporating hexa-oxy-benzene $C_6(OH)_6$ with dilute KOH in an open dish (Nietzki a. Benckiser, *B.* 18, 509).

Preparation.—By boiling the hydrochloride of diamidotetraoxybenzene $C_6(NH_2)_2(OH)_4$ (1 pt.) with K_2CO_3 (4 pts.) precipitated MnO_2 (3 pts.) and water (60 pts.) for ½ hour; on adding $BaCl_2$ to the filtrate acidified with HCl the sparingly soluble barium croconate separates in golden-yellow plates; the yield is 70 p.c. of the theoretical (Nietzki a. Benckiser, *B.* 19, 293).

Properties.—Sulphur-yellow plates or grains (containing 3aq). V. sol. water, sol. dilute alcohol. Di-basic acid. Forms a sparingly soluble red crystalline anilide. Heated with NH_3 it gives the tri-imide of leuconic acid. With hydroxylamine it gives the penta-oxim of leuconic acid $C_5(NOH)_5$. By H_2S it is converted into thio-croconic acid $C_5H_2O_4S$. It is reduced by $SnCl_2$, SO_2, or zinc-dust to the colourless hydro-croconic acid $C_5H_4O_5$, which is readily reoxidised to croconic acid. By heating potassium croconate with HI it is reduced to 'croconic-acid-hydride' ($C_{10}H_6O_{10}$?), whose salts are deep coloured; by further reduction it gives a colourless substance which is readily reoxidised to the hydride. Croconic acid is oxidised by HNO_3 to leuconic acid C_5O_5.

Salts.—K_2A″: long dark-yellow needles (N. a. B.).—K_2A″ 2aq : orange needles (G.).—HKA″: brownish-yellow needles with violet reflex.—NaKA″ *x*aq : yellow rhombic plates, become red on drying.—CaA″ 3aq : yellow powder (W.).—BaA″ 1½aq : lemon-yellow powder, insol. water, v. sl. sol. HClAq.—PbA″ 2aq : lemon-yellow pp., insol. water. — CuA″ 3aq : sparingly soluble orange needles with blue reflex.—Ag_2A″ : orange pp.

Aniline salt A″$(NH_3Ph)_2$: yellow plates, m. sol. water.

Di-anilide $C_5(HO)_2O(NPh)_2$: slender red needles. Formed by heating the aniline salt with alcohol. V. sl. sol. all solvents but aniline. Dissolves in aqueous alkalis, and on heating the solution croconic acid and aniline are regenerated. Heated with aqueous NH_3 it is converted into croconamic acid $C_5H_3NO_4$ (Nietzki a. Benckiser, *B.* 19, 772).

Mono-phenylhydrazide $C_5(OH)_2O_2(N_2HPh)$: [above 300°]; yellow needles; v. sol. alcohol, insol. water. Di-basic acid.—K_2A'': nearly black coppery needles, v. sol. water with a brown colour.

Tolylene-o-diamide v. CROCONIC-DI-TOLUQUINOXALINE.

'**Croconic-acid-hydride**' $C_5H_4O_5$ or $C_{10}H_6O_{10}$ *i.e.*

$\mathrm{CH(OH)}\left\langle\begin{array}{l}\mathrm{C(OH).CO}\\ \quad|\qquad\quad|\\ \mathrm{C(OH).CO}\end{array}\right.$

(?). *The 'hydrocroconic acid' of Lerch* (*A.* 124, 20). Formed by heating potassium croconate with HI. Its salts are dark-coloured. By further reduction it is converted into a colourless substance, which is readily reoxidised to the hydride.—$C_5H_2O_5Ba$ 2aq or $C_{10}H_2O_{10}Ba_2$ 4aq: deep orange crystalline powder or amorphous flocculent pp.—$PbC_5H_2O_5$: red pp. (Nietzki a. Benckiser, *B.* 19, 297).

CROCONIC-TOLUQUINOXALINE $C_{12}H_8N_2O_3$ *i.e.*

$C_7H_6\left\langle\begin{array}{c}N\\ |\\ N\end{array}\right\rangle C_5O(OH)_2$

Croconic-acid-tolylene-o-diamide. Formed by mixing a cold aqueous solution of croconic acid with a salt of tolylene-*o*-diamine. Fine needles, with green reflex. Sol. alcohol with a brown colour, insol. water. Dibasic acid. — $A''K_2$: black metallic needles (Nietzki a. Benckiser, *B.* 19, 776).

CROCOSE (*saffron-sugar*) $C_6H_{12}O_6$. Trimetric crystals. Sweet taste. Dextrorotatory. Its reducing power is half that of dextrose. Formed, together with crocetin, by the action of dilute acids on crocin (Kayser, *B.* 17, 2232; *cf.* Rochleder a. Mayer, *J.* 1858, 476; *Sitz. W.* 29, 3).

CROSSOPTERINE. An amorphous alkaloid in the bark of *Crossopterix Kotschyana* (Hesse, *B.* 11, 1546).

CROTACONIC ACID $C_3H_4(CO_2H)_2$. [119°]. Solidifies at 90°. From cyano-crotonic acid which changes spontaneously into acid ammonic crotaconate (Claus, *A.* 191, 74; *B.* 10, 822).

Properties.—Crystals. Sol. water, alcohol, and ether. At 140° it decomposes, giving off CO_2 (difference from itaconic, citraconic, &c.). Combines with HBr forming an acid $C_3H_5Br(CO_2H)_2$ [141°].

Salts.—$(NH_4)HA''$.—KHA'' 2aq.—K_2A''aq.—PbA''.—Ag_2A''.

Dimethyl ether Me_2A''. S.G. $\frac{15}{}$ 1·14. Sol. alcohol and ether.

Isomerides: CITRACONIC, ITACONIC, MESACONIC, and ETHYLIDENE-MALONIC, ACIDS.

CROTONIC ACID $C_4H_6O_2$ *i.e.* $CH_3.CH{:}CH.CO_2H$. Mol. w. 86. [72°]. (185° cor.). S. 8 at 19°. R_∞ 35·71 in a 4·12 p.c. aqueous solution (Kanonnikoff).

Occurrence.—In crude wood vinegar (Krämer a. Grodzki, *B.* 11, 1359). Its name is derived from croton oil, from which it was erroneously supposed to be formed by saponification (Pelletier a. Caventou, *J. Ph.* 4, 289; 11, 110; Schlippe, *A.* 105, 1; Geuther, *Z.* [2] 5, 270).

Preparation.—1. By oxidation of crotonic aldehyde (from acetic aldehyde) in the air or by moist Ag_2O (Kekulé, *B.* 3, 604; *Z.* [2] 6, 705).—2. From allyl cyanide (*v.* vol. i. p. 136) obtained from mustard oil (Will a. Körner, *A.* 125, 273).—3. By distillation of (β)-oxy-butyric acid (Wislicenus, *Z.* 1869, 325).—4. By boiling α-bromo-butyric ether with alcoholic KOH (Hell a. Lauber, *B.* 7, 560).—5. From isocrotonic acid by intramolecular change brought about by heating to 175° (Hemilian, *A.* 174, 322).—6. From malonic acid (1 mol.), paraldehyde (1 mol.), and excess of glacial acetic acid at 100° (Komnenos, *A.* 218, 149). The yield is good (50 p.c.).—7. By heating pyruvic acid (1 pt.) with Ac_2O (5 pts.) and NaOAc (5 pts.) at 170° (Homolka, *B.* 18, 987).—8. By reduction of aceto-acetic ether with sodium-amalgam (Beilstein a. Wiegand, *B.* 18, 482).

Properties.—Trimetric plates (by sublimation) or monoclinic crystals (from water); $a{:}b{:}c = 1{:}1{\cdot}8065{:}1{\cdot}5125$; $\beta = 131°$. M. sol. hot ligroïn.

Reactions.—1. *Potash-fusion* forms only acetic acid.—2. Not reduced to butyric acid by *sodium amalgam* (Körner, *J.* 1866, 318; *A.* 137, 233; *cf.* Bulk, *A.* 139, 62).—3. Br gives αβ-di-bromo-butyric acid.—4. Conc. HBr at 100° gives α- and a little β- bromo-butyric acid.—5. HOCl gives chloro-oxy-butyric acid.—6. Conc. HNO_3 gives acetic and oxalic acids.—7. *Chromic acid mixture* gives aldehyde and acetic acid (Kekulé, *A.* 162, 315).—8. Aqueous *ammonia* forms α-amido-butyric acid (Engel, *C. R.* 106, 1677).

Salts.—KA': deliquescent needles.—KHA'_2: plates (from alcohol) (Pinner, *B.* 17, 2008).—NaA'. S. (alcohol) 1·4 at 14°.—BaA'_2: easily soluble plates.—CaA'_2: v. sol. cold, sl. sol. hot, water (Beilstein a. Wiegand, *B.* 18, 482).—PbA'_2: stellate groups of needles.—ZnA'_2 2aq (Alberti, *B.* 9, 1194).—AgA': curdy pp.

Methyl ether MeA'. (121°). S.G. $\frac{4}{}$ ·9806. $\mu_D = 1{\cdot}4138$ (Kahlbaum, *B.* 12, 344).

Ethyl ether EtA'. (139° cor.). $\mu_D = 1{\cdot}424$. R_∞ 50·45 (Brühl, *A.* 235, 8; *B.* 14, 2798). S.G. $\frac{15}{15}$ ·9268; $\frac{25}{25}$ ·9185. M.M. 7·589 at 24·4° (Perkin, *C. J.* 45, 537).

Amide. Syrup; v. sol. water (B. a. W.). A crystalline amide [c. 151°] was obtained by Pinner (*B.* 17, 2008) by exposing to the air the hydrochloride of β-chloro-butyrimido-ether $CH_3.CHCl.CH_2.C(OEt).NH_2Cl$.

Iso-crotonic acid $C_4H_6O_2$ *i.e.* $CH_2{:}CH.CH_2.CO_2H$ (?). *Quartenylic acid.* (172° cor.). S.G. $\frac{25}{}$ 1·018. Occurs in crude wood vinegar (Grodzki a. Krämer, *B.* 11, 1359).

Preparation.—Aceto-acetic ether is treated with PCl_5 and the product poured into water. The two chloro-crotonic acids formed are distilled with steam. The chloro-iso-crotonic acid alone passes over. It is reduced by sodium amalgam, and the iso-crotonic acid is extracted by ether. On evaporation this leaves iso-crotonic acid as a syrup.

Properties.—Liquid, smelling like butyric acid; miscible with water. At 175° it changes to the preceding isomeride (Hemilian, *A.* 174, 322).

Reactions.—1. *Bromine* acting on a solution of iso-crotonic acid dissolved in CS_2 produces the dibromide of ordinary solid crotonic acid (*v.* DI-BROMO-BUTYRIC ACID) (Kolbe, *J. pr.* [2] 25, 397).—2. *Potash-fusion* gives only acetic acid.—3. *Sodium amalgam* has no action.

Salts.—$CaA'_2 2aq$: very soluble needles.—$BaA'_2 2aq$: small crystals, v. e. sol. water.—$PbA'_2 aq$. [68°].—AgA'.

Ethyl ether EtA. (136°). S.G. $\frac{19}{}$ ·927 (Geuther, *Z.* 1871, 243).

Isomeride of crotonic acid $C_4H_6O_2$. [19°]. (181°). From vinaconic acid (*q.v.*) by distillation (Röder, *A.* 227, 24).

Salts.—$CaA'_2 6aq$.—$BaA'_2 2aq$.—AgA'.

Constitution.—From its formation, from $CH_2:CH.CH(CO_2H)_2$ it should be vinyl-acetic acid, $CH_2:CH.CH_2.CO_2H$, a formula, attributed, without sufficient reason, to isocrotonic acid.

Another isomeride of crotonic acid *v.* METHACRYLIC ACID.

Dibromide of crotonic acid *v.* DI-BROMO-BUTYRIC ACID.

Derivatives of crotonic acid *v.* BROMO-CROTONIC ACIDS and CHLORO-CROTONIC ACIDS.

CROTONIC ALDEHYDE C_4H_6O *i.e.* $CH_3.CH:CH.CHO$. Mol. w. 70. (105°). S.G. $\frac{0}{}$ 1·033.

Formation.—1. By heating aldehyde with $ZnCl_2$ and a little water to 100°, aldol being first formed: $2CH_3.CHO = CH_3.CH(OH).CH_2.CHO = CH_3.CH:CH.CHO + H_2O$. Other dehydrating agents may be used (Lieben, *A. Suppl.* 1, 117; Kekulé, *Z.* [2] 5, 572; *A.* 162, 92; Bauer, *A.* 117, 141; Lieben a. Zeisel, *M.* 1, 820). Hence it occurs in crude spirit (Krämer a. Pinner, *B.* 3, 75).—2. By the distillation of aldol (Wurtz, *C. R.* 87, 45).—3. From vinyl bromide by successive treatment with H_2SO_4 and water (Zeisel, *A.* 191, 371).—4. From acetylene by successive treatment with H_2SO_4 and water (Lagermarck a. Eltekoff, *B.* 10, 637).

Preparation.—Paraldehyde (1 pt.), water (1 pt.), and conc. HClAq (2 pts.) are kept at 25° for 5 days. The liquid is then neutralised with Na_2CO_3, the ppd. dialdane is filtered off, and the filtrate extracted with ether. The ethereal extract is distilled under reduced pressure, and the crude aldol (½ pt.) (85° to 120° at 200 mm.) is split up into water and crotonic aldehyde ($\frac{1}{5}$ pt.) by distillation under ordinary pressure (Newbury, *C. R.* 92, 196; *Am.* 5, 113).

Properties.—Pungent liquid; m. sol. water. Oxidised in the air or by Ag_2O to crotonic acid. It forms a crystalline combination with $NaHSO_3$, m. sol. water, whence Na_2CO_3 does not liberate the aldehyde (Lieben a. Zeisel, *M.* 1, 818).

Reactions.—1. PCl_5 gives di-chloro-butylene (126°).—2. By saturation with HCl in the cold it is converted into β-chloro-butyric aldehyde [97°].—3. Br gives oily αβ-di-bromo-butyric aldehyde (L. a. Z.).—4. Cl forms αβ-di-chloro-butyric aldehyde, and finally αβ-di-chloro-butyryl chloride (Zeisel, *M.* 7, 359).—5. *Iron* and *acetic acid* reduce it to butyric aldehyde, butenyl alcohol, and *n*-butyl alcohol (L. a. Z.).—6. Ac_2O gives the di-acetyl derivative of crotonic orthaldehyde $CH_3.CH:CH.CH(OAc)_2$ (205°–210°). S.G. $\frac{14}{}$ 1·05 (Lagermarck a. Eltekoff, *J. R.* 11, 79).—7. Dilute HCl at 0° forms, by hydration, a little aldol, paraldol, and dialdane (Wurtz, *C. R.* 97, 1169).—8. *Ammonia* forms tri-crotonylene-amine $C_{12}H_{24}N_4$. At −20° ammonia passed into an ethereal solution of the aldehyde forms $C_8H_{16}N_2O$ (Combes, *C. R.* 96, 1862).—9. Crotonic aldehyde (1 pt.) treated with *aldehyde* (2 pts.) and $ZnCl_2$ at 100° forms an aldehyde C_6H_8O (172°) Kekulé, *A.* 162, 105).—10. By heating with HCN and saponifying the product pentinoic acid $CH_2:CH.CH:CH.CO_2H$ is formed (Lobry de Bruyn, *Bl.* [2] 42, 159).

Derivative $CH_3.CH:CH.CHCl(OEt)$. (134°). From di-chloro-butylene and alcoholic KOH (Kekulé, *A.* 162, 99).

CROTONITRILE *v.* ALLYL CYANIDE.

CROTON OIL. A fatty oil contained to the amount of 50 p.c. in the seeds of *Croton Tiglium*, a euphorbiaceous plant. It is purgative, and inflames the skin (Schlippe, *A.* 105, 1; Mayer, *N. Jahr. pr. Pharm.* 10, 318; Geuther a. Fröhlich, *Z.* [2] 6, 26, 549). It contains glycerides of formic, acetic, isobutyric, isovaleric (isobutylformic) and tiglic acids (E. Schmidt a. J. Berendes, *A.* 191, 94; *B.* 10, 835; *Ar. Ph.* [3] 13, 213). The nature of the purgative principle has not been satisfactorily made out (Senier, *Ph.* [3] 14, 446; Kobert, *Chem. Zeit.* 11, 416).

CROTONYL ALCOHOL *v.* BUTENYL ALCOHOL, vol. i. p. 639.

CROTONYLENE *v.* BUTINENE.

TRI-CROTONYLENE-AMINE $C_{12}H_{24}N_4$. (c. 190°) at 40 mm. Formed by heating aldol with excess of aqueous NH_3 at 160°; or from crotonic aldehyde and NH_3 at 100° (Wurtz, *C. R.* 88, 1154). Efflorescent prisms (containing 6aq); sl. sol. cold water, v. sol. alcohol. HCl at 150° resinifies it.

Salts.—Crystallise readily from acid solutions.—$B'3HCl$: hexagonal prisms.—$B'3HNO_3$: hexagonal prisms.—$B'H_3Cl_3(PtCl_4)_2$.—$B'_2H_8Cl_8(PtCl_4)_3$.—$B'H_4Cl_4AuCl_3$.—$B'H_3Cl_3AuCl_3 2aq$.—$B'_2H_8Cl_8(AuCl_3)_5$.

CROTONYLENE GLYCOL *v.* ERYTHRITE and DI-OXY-BUTYLENE.

CROTYL ALCOHOL *v.* BUTENYL ALCOHOL.

CROTYLAMINE $C_4H_7NH_2$. (75°–80°). Prepared by the action of alcoholic NH_3 on isobutylene bromide. Liquid (Hofmann, *B.* 7, 514; 12, 992).—$(B'HCl)_2PtCl_4$. Yellow scales.

ISO-CROTYL BROMIDE *v.* BROMO-BUTYLENE.

ISO-CROTYL CHLORIDE *v.* CHLORO-ISOBUTYLENE.

CROTYL IODIDE *v.* IODO-BUTYLENE.

CROTYL THIOCARBIMIDE $C_4H_7N.CS$. (179°). From crotylamine (Hofmann, *B.* 7, 516). Pungent liquid.

CROTYL-THIO-UREA $C_4H_7NH.CS.NH_2$. [85°]. From the preceding and NH_3(H). Crystalline.

CRYPTIDINE $C_{11}H_{11}N$. (274°). A homologue of quinoline occurring in coal tar (Greville Williams, *Chem. Gaz.* 1856, 283).

Cryptidine $C_{11}H_{11}N$. (270°). Prepared by the dry distillation of xylidine-acroleïn (Leeds, *A. C. J.* 5, 2). Reddish-yellow oil. Disagreeable odour. Bitter taste.—$B'HCl$: fine thin tabular crystals.—$B'H_2PtCl_6$: fine yellow crystals. Sol. water, insol. alcohol.

CRYPTOPHANIC ACID $C_5H_9NO_5$. An acid said to occur in normal human urine (Thudichum, *C. J.* 23, 116; 34, 81). The urine is evaporated to one-fourth of its bulk and Fe_2Cl_6 added. The pp. contains the iron salts of cryptophanic, paraphanic, hippuric, and benzoic acids. It may be decomposed by baryta. Amorphous gum, v. e. sol. water.—PbA''.—CaA''.

CRYPTOPINE $C_{21}H_{23}NO_5$. [217°]. S. (alcohol) ·08 (Smith). S.G. 1·35 (Schröder *B.* 13, 1075). A base occurring in very small quantity in opium (T. a. H. Smith, *Ph.* [2] 8, 595, 716; Hesse, *A. Suppl.* 8, 299; *A.* 176, 200; Kauder, *Ph.* [3] 18, 250). Ppd. by adding NaOH to the mother-liquor, from which codeïne, narceïne, thebaïne, and papaverine have been separated. Six-sided prisms (from alcohol); when freshly ppd. it is soluble in ether, but it slowly separates from the solution. Sl. sol. boiling alcohol, v. sl. sol. benzene and ligroïn, m. sol. chloroform. Dissolves in excess of KOHAq. Inactive to light. Conc. (impure) H_2SO_4 gives a blue colour turned orange by KNO_3. Fe_2Cl_6 gives no colour. Not decomposed by HCl.

Salts.—Separate from aqueous solution as jellies, but subsequently become crystalline.—B'HCl 6aq: soft mass of crystals (from alcohol).—B'HCl 5aq. — $B'_2H_2PtCl_6$ 6aq. — $B'_2H_2Cr_2O_7$. — $B'H_2C_2O_4$. S. ·3 at 12°.—$B'C_4H_6O_5$ 4aq. S. ·15 at 10°.—$B'C_6H_2(NO_2)_3OH$ aq.

Meconate $B'_2C_7H_4O_7$ 10aq: sl. sol. boiling water.

Nitro-cryptopine $C_{21}H_{22}(NO_2)NO_5$. [185°]. From cryptopine and HNO_3 (S.G. 1·06) at 55°. Dark-yellow crystalline powder. Insol. water and KOHAq. Conc. H_2SO_4 dissolves it with blood-red colour.—B'HCl 3aq.—$B'_2H_2PtCl_6$ 10aq.—$B'HNO_3$.—**Oxalates** $B'_2H_2C_2O_4$ 12aq. S. 6·8 at 16° and $B'H_2C_2O_4$ 3aq.

CRYSTALLIN *v.* PROTEÏDS.

CRYSTALLISATION.—The examination of a crystal and the determination of its form and properties may serve as a means of recognising and defining any given body. But besides this practical application, the examination may help to find an answer to the question: What is the connexion between the chemical constitution and the crystalline form of bodies?

The complete examination of the form and properties of a crystalline substance may demand a thorough knowledge of crystallography, and also skill in the use of complicated and costly instruments; but a general knowledge of the principles of the subject, and of the use of a geological microscope, such as ought to be found in every laboratory, will very often enable the chemist approximately to determine the form of a substance, the identity or non-identity of two samples, or the homogeneous character of his preparations. The following account may serve as a general view of the subject, or as an introduction to a more complete study; it is necessarily incomplete, and for further details special books must be consulted, such as Groth's *Physikalische Krystallographie*; current literature being found in the *Zeitschrift für Krystallographie*, and the different mineralogical journals.

A crystal may be described as a solid homogeneous body bounded by plane faces that are arranged around the body in a certain regular manner, which is constant for each chemical compound. Neither the number of faces that bound a crystal, nor the shapes of these faces, are constant and characteristic, since both may vary considerably with very slight alterations of external conditions at the time of crystallisation; but the regularity, or the symmetry which all the faces bear to each other, and the manner in which the faces occur in groups or sets or '*forms*,' is constant and characteristic.

Single or Simple crystalline form.—That all the faces of a crystal do not belong to the same form is often strikingly evident by a difference in colour, as in many of the platinocyanides, or in the condition of the faces, some of which are smooth and lustrous, while others are dull or streaked with numerous fine lines, or are rough with little pittings, or appear to be made up of numerous scales, and then show a pearly lustre; such differences are to be noticed on crystals of magnesium sulphate, quartz, salt, alum, potassium ferrocyanide, potassium chlorate, gypsum, copper sulphate, &c. The same fact is often also to be noticed in another way, viz. by the appearance of splits or cleavage planes that run parallel to certain faces but not to others, as in calcite and potassium ferrocyanide; often where such are not manifest the crystal may be easily split or cleaved parallel to certain faces but not to others, as with gypsum, cane sugar, magnesium sulphate, &c. Differences in the forms of the faces of crystals are often shown by the way in which the crystal during its growth has inclosed foreign substances, as bubbles of liquid or gas, or fragments of solid substances that were suspended in the solution, viz. the inclosures are distributed in lines or planes parallel to certain edges or planes of the crystal, but not to others. In examining a crystal all such observations are of the greatest service, as they at once give a means of classifying the may-be numerous faces into their proper sets or forms.

A crystal may be completely bounded by only one set of faces, *e.g.* a cube of rock salt; but there are several crystalline forms that are not capable of inclosing space, as the various prisms and pinacoids, or basal planes, and such forms necessarily never occur alone. The minimum number of crystalline forms that may occur on a crystal is limited only by the condition that they must completely inclose the crystal; the maximum number is unlimited; but however many there may be, all are correlated by an empirical law, known as the *rationality of indices*, and the symmetry of faces constituting each individual form is the same.

This last statement, though strictly true, is apparently not so in several cases, as certain forms show externally a geometrical symmetry apparently other than that which belongs to their internal structure; thus both salt and iron pyrites crystals often exhibit no other form than the cube, and therefore are apparently possessed of the same kind and amount of symmetry, yet other forms that occur in these two substances show that iron pyrites is really possessed of a lower degree of symmetry than sodium chloride (*v. Hemihedral forms*, p. 283).

Symmetry of crystalline forms.—A solid figure may be symmetrical about a point, or about a plane, or a number of planes. A solid figure is *symmetrical about a point* when any number of particles on the surface being joined to the central point by straight lines, these being produced to equal distances on the other side of the centre shall exactly coincide with a series of similar particles. This kind of symmetry only demands that to every face there be a second and parallel one; it is only met with in the asymmetric (*i.e.* without symmetry) crystals, as, for instance, copper sulphate and potassium anhydrochromate.

A solid figure is *symmetrical about a plane* when from any number of particles on the surface perpendiculars being drawn to the plane and produced equal distances on the other side of the plane, the points so found shall exactly coincide with a series of similar particles; in other words, the one half is the mirrored image of the other, the mirror being the *plane of symmetry*. Thus a cube is symmetrical about the plane *a c g e*. A line perpendicular to the plane of symmetry is called an *axis of symmetry*, and about a central point in this axis the figure is also symmetrical. Thus (fig. 1), starting with *a c g e* as a plane of symmetry, and *a b f e* as any given plane, the existence of *a d h e* and *d c g h* necessarily follows, as the former is the image mirrored in the plane of symmetry, and the latter is the plane symmetrical to the first with regard to the central point; the existence of *b c g f* follows similarly from either or both of the last two faces.

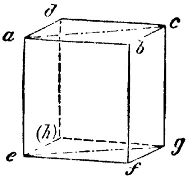


FIG. 1.

Besides the above-mentioned plane *a c g e* there are five others that divide the cube in exactly the same fashion, viz. the planes *b d h f*, *b a h g*, *c f e d*, *a f g d*, and *b e h c*, and these make therefore a *set of* six *planes of symmetry*; and the corresponding six axes of symmetry are the lines *m n*, *o p*, *q r*, *s t*, *u v*, and *w x*, joining the centres of the opposite edges (fig. 2).

A plane that is at right angles to two planes of symmetry contains two axes of symmetry, and

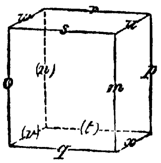

FIG. 2.

must therefore itself be a plane of symmetry; and if, as in the case now considered, the two contained axes of symmetry are similar, then the symmetry of the new plane is of a higher order than that of the two others. The above six planes may be taken two at a time in three different ways, and thus a set of three new planes of a higher order are found; they are called *planes of principal symmetry* as distinguished from *planes of ordinary symmetry*; they are *q s r t*, *w u x v*, and *o m p n* (fig. 2), and the corresponding *axes of principal symmetry* are the lines A B, C D, and E F (fig. 3). As a plane of principal symmetry contains two, and in the hexagonal system three, exactly similar axes of symmetry, the appearance and

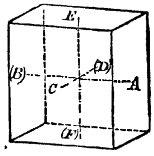

FIG. 3.

actual position of a crystal is not changed by rotating it about the axis of principal symmetry such that first one and then another of the similar axes of ordinary symmetry come to occupy the same position. In this way a plane of principal symmetry may be most readily distinguished from a plane of ordinary symmetry.

Division of crystals into classes.—A crystal can only be possessed of a set of three exactly similar axes of principal symmetry, or of one such axis, or it must be devoid of any such; and all crystals may accordingly be divided into three great classes: (1) Crystals possessed of three axes of principal symmetry must necessarily contain also a set of six axes of ordinary symmetry (as explained above in the case of the cube), and all such are said to belong to the *Regular system.* (2) Crystals possessing one axis of principal symmetry must necessarily contain axes of ordinary symmetry at right angles to the first. The number of these axes of ordinary symmetry may be either (1) a set of three inclined to each other at one-third of four right angles, with, as a necessary consequence, a second set of three, also inclined to each other at one-third of four right angles, but removed from the first set by one-sixth of four right angles, or (2) a set of two at right angles to each other, with, as a necessary consequence, a second set of two also at right angles to each other, but removed from the first set by half a right angle. Crystals satisfying the first set of conditions are said to belong to the *Hexagonal system*, and those satisfying the second set to the *Quadratic system.* (3) Crystals destitute of any axis of principal symmetry may yet contain axes of ordinary symmetry, and the possible cases are (i) three sets of one axis each, *i.e.* three dissimilar axes, which must of necessity be at right angles to each other, (ii) one single axis, and (iii) no axis of symmetry at all. Crystals satisfying these three conditions are said to belong to the *Rhombic system*, to the *Monosymmetric* (formerly called the monoclinic) *system*, and to the *Asymmetric* (formerly called the triclinic) *system*.

Thus all crystals may be divided geometrically into the above six systems; and it is a very important fact that exactly the same division is effected by a consideration of all the physical properties, more especially the optical and mechanical ones, viz. tensional strength, the thermal and electrical properties being difficult of investigation, and also by a mathematical discussion of the possible ways of arranging a number of points in space. Crystals of the regular system behave optically like amorphous bodies, they are singly refractive and are therefore said to be *isotropic*. All other crystals are doubly refractive and are called *anisotropic*; they are divided into two classes according as they contain one direction or no direction along which a beam of light may travel and then emerge from the crystal without suffering double refraction; those possessed of this axis of single refraction are termed *optically uniaxial*. The hexagonal and quadratic crystals are both uniaxial, and optically they are undistinguishable; in both cases the tensional strength in the plane of principal symmetry varies with the direction in which it is determined, but while hexagonal crystals show three directions of minimum and of maximum strength, quadratic crystals show only two. Anisotropic crystals that are not uniaxial have been called *optically biaxial*, though they have not two directions that are truly void of the power of doubly refracting light as above defined. When a properly-cut section of a biaxial crystal is examined in 'convergent polarised light' the two optical axes are seen surrounded by dark and light rings gradually shading into each other, and as the 'interference figure' is not the same for light of any two colours, so the rings, merging more or less completely into each other, are fringed with colour, and by a careful examination of the coloured fringes it can be determined to which of the last three systems the crystal belongs; viz. if rhombic, the figure is symmetrical about both diameters A B and C D, and consequently also about the central point E; if monosymmetric, the figure is symmetrical about one or other of the diameters or about the central point, according to circumstances; if asymmetric, the figure is void of symmetry (fig. 4).

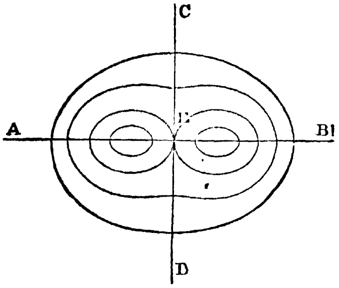

Fig. 4 (diagrammatic).

In studying the geometrical properties of crystals, certain lines must be taken within the crystal, to which all the faces may be referred; these lines, of which there must be three, are called the *crystallographical axes*, and they are represented by the letters a, b, c, while the inclinations which they make with each other are represented where necessary by the letters α, β, γ, viz. $a{:}b = \gamma$; $a{:}c = \beta$; and $b{:}c = \alpha$. In each system the crystallographic axes are chosen in such a way that the different forms may be most simply expressed. By this is to be understood that each of the different faces that together make a single crystalline form is to be related to the axes in exactly the same numerical way, or in other words the geometrical symbol for each of the faces of a form is exactly the same if the signs be omitted that denote a face to be at the top, front, right hand, &c. In the regular system the three axes of principal symmetry are chosen, and as these are all exactly similar and equal, the expression a, b, c becomes a, a, a, and as 'a' stands thus alone it may itself be considered as unity, and the axial expression thus becomes $a = a = a = 1$ or $a = 1$; the expression for the axial angles is always $\alpha = \beta = \gamma = 90°$. In the hexagonal system one set of three axes of ordinary symmetry (two of these three axes would be sufficient, but for the sake of completeness it is convenient to include the third, this is also not without its advantages), and the axis of principal symmetry, are chosen; as the first three are exactly alike, but are independent of the last, the expression for the axes a, b, c becomes a, a, a, c; one of these may be made equal to unity, most conveniently a, and the crystallographical axes are expressed $a{:}c = 1{:}c$. The axial angles are in all cases $a{:}c = 90°$ an $a.a = 120°$. Here notice that any and every crystal of the regular system has its axes represented by $a = b = c = 1$ and $\alpha = \beta = \gamma = 90°$, and these facts do not therefore need to be repeatedly stated, for they are comprehended in the expression 'regular system.' The same holds good with the axial angles of any and every hexagonal crystal, viz. $a{:}a{:}a = 120°$ and $a{:}c = 90°$; but with the relative lengths of the axes it is otherwise, the ratio of $a{:}c$ is not the same for any two substances, and in describing a hexagonal crystal the *crystallographical constant*, the *axial ratio* $a{:}c$, must be accurately measured and given; thus for example in lead dithionate it is as 1:1·5160, while in strontium dithionate, which has almost exactly the same form and is therefore said to be *isomorphous*, it is as 1:1·5024.

These crystallographical axes are not to be considered as definite lines, having definite lengths, but as directions, determined by the symmetry of the crystal, and consequently endowed with certain properties—*i.e.* like axes must be cut by the like number of faces at the like angles—and upon which the relative lengths of the intercepts cut off by the various faces may be calculated trigonometrically from the measurements of the interfacial angles. These angles are always measured by means of a reflecting goniometer, above the centre of whose graduated circle the edge, over which the angle is to be measured, is exactly placed by means of adjusting screws. About the same centre the crystal and a collimator or telescope may be made to revolve; the position of a beam of light incident upon the crystal, and the positions of the reflected beams from the two lustrous crystal faces, are thus measured, and the interfacial angle determined. The method of calculation may be exemplified by reference to a beryl crystal. Here there are four sets of faces, each of which, of course, cuts the axes differently, and one of these manners of cutting must be chosen as the standard (fig. 5). The basal faces (0001) cut only the vertical axis, the prismatic faces ($10\bar{1}0$) cut only the horizontal axes, and hence neither of these forms alone allows a determination of the ratio $a{:}c$.

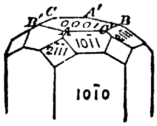

FIG. 5.

But the faces of each of the two pyramids $(10\bar{1}1)$ and $(2\bar{1}\bar{1}1)$ cut both horizontal and vertical axes; for the sake of simplicity the faces $(10\bar{1}1)$ are chosen as those of the primary pyramid, and the three horizontal axes are thus fixed as being parallel to AA′, BB′ and CC′. The angle $10\bar{1}1{:}0001$ having been measured and found 150° 3′ 20″, $a{:}c$ is easily calculated thus;

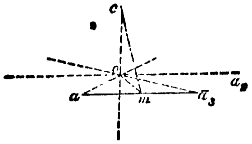

FIG. 6.

$\tan\,(180° - 150°\ 3'\ 20'') = \frac{oc}{om}$, but if oa = unity, then

$$om = \frac{\sqrt{3}}{2}, \text{hence } oc = \frac{\sqrt{3}}{2} \tan\,(180° - 150°\ 3'\ 20'')$$

$= 0{\cdot}4989$; that is, $a{:}c = 1{:}0{\cdot}4989$ (see fig. 6).

If, however, the angle of the pyramid over a terminal edge, *i.e.* $(10\bar{1}1){:}(01\bar{1}1)$ had been measured and found equal to 151° 5′ 40″, then by describing from the point a a spherical triangle cutting the face of the crystal in AB (fig. 7), the plane of principal symmetry in AC, and the plane of ordinary symmetry in CB, the side a can be found from the known data, $B = \frac{1}{2}(151°\ 5'\ 40'')$, $b = 60°$, and $C = 90°$;

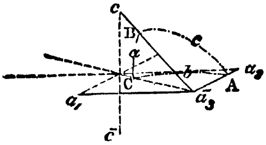

FIG. 7.

$$\text{thus } \sin c = \frac{\sin b}{\sin B}, \text{ hence } c = 63°\ 25'\ 20'',$$

$$\text{then } \tan \tfrac{1}{2}a = \tan \tfrac{1}{2}(c - b)\frac{\sin \frac{1}{2}(B + C)}{\sin \frac{1}{2}(C - B)}$$

$$= \frac{\tan 1°\ 42'\ 40'' \times \sin 82°\ 46'\ 25''}{\sin 7°\ 13'\ 35''};$$

hence $\frac{1}{2}a = 13°\ 15'\ 25''$, and $a = 26°\ 30'\ 50''$; and lastly $\frac{\text{axis } c}{\text{axis } a} = \tan$ of 26° 30′ 50″, from which the value for the vertical axis $c = 0{\cdot}4989$ is again found.

For any given crystal the axial ratios are thus exactly determinable, but where any arbitrary choice has been made, as in this instance, then the same is adopted by all subsequent observers unless good reasons are found for making an alteration.

In the quadratic system one of the two sets of two axes of ordinary symmetry, and the axis of principal symmetry, are chosen; the axial angles are in all cases 90°; the expression a, b, c, thus becomes a, a, c, and, as in the hexagonal system, the axial ratio $a{:}c$ has to be actually determined in every individual case. In the rhombic system the three axes of ordinary symmetry are chosen; the axial angles are in all cases 90°; as these three axes are not similar, the expression a, b, c, remains as such; making one equal to unity, the other two constants have to be determined in every individual case. In the monosymmetric system the axis of symmetry is chosen as one crystallographical axis; the other two axes must lie in the plane of symmetry, but otherwise their positions are perfectly arbitrary; for simplicity's sake, they are chosen parallel to two well-defined edges or faces on the crystal; in this system a, b, c, are quite independent and have to be determined, b is generally the axis of symmetry and is made equal to unity; the inclinations of $b{:}a$ and $b{:}c$ are in all cases 90°, but the inclination of $a{:}c$ (axial angle β) is variable and must be determined. In the asymmetric system the crystallographic axes are chosen quite arbitrarily; generally however they are chosen parallel to three prominent edges of the crystal; they are quite independent of each other, therefore of unequal lengths, and moreover no two of them are inclined at right angles to each other; for asymmetric crystals there are thus five constants to be determined.

Relation of faces to axes. Rationality of indices.—When a number of sets of faces on a crystal are referred to the axes whose relative lengths have been found as just explained, it is noticed that the intercepts cut off can in all cases be expressed as some simple multiple or sub-multiple of the fundamental axial lengths. This is known as the *rationality of the indices.* Thus in the case of the beryl crystal (fig. 5), while the faces of the primary pyramid cut the axes $a{:}a{:}a{:}c$ at the distances $1{:}\infty{:}1{:}0{\cdot}4989$, those of the faces $(2\bar{1}\bar{1}1)$ cut at $1{:}2{:}2{:}0{\cdot}9978$; here 1 is 1 × 1, 2 is 2 × 1, and 0·9978 is 2 × 0·4989, and the numbers 1, 2, 2, 2 are here indices. The indices are generally expressed by very simple numbers, as 1, 2, 3, 4, 5, 6, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{2}{3}$, &c., but in some cases the ratios are not so simple.

The indices of a face may be measured in two ways—the one known as Neumann's system, and the other as Miller's. Let the relative lengths of any set of primary axes be expressed by the letters a, b, c, and let there be another face on the crystal which cuts the axes at some other distances, say $2a$, $3b$, $4c$, from their centre. According to Neumann the indices of this face are $\frac{2a}{a}$, $\frac{3b}{b}$, $\frac{4c}{c}$ *i.e.* 2, 3, 4; following Miller, however, the indices are the reciprocals of those of Neumann, viz. $\frac{a}{2a}$, $\frac{b}{3b}$, $\frac{c}{4c}$, *i.e.* $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, or, simplifying, the expression becomes 6, 4, 3.

Of course there will be more than one face having this symbol, the number depending on the symmetry of the crystal, but the relative positions of any of these may be exactly denoted by the following device. In all the systems the extremities of the axes forming the front upper right corner are called positive, and are simply written *a*, *b*, *c*, &c., while the opposite extremities are called negative, and are written $\bar{a}$, $\bar{b}$, $\bar{c}$, &c. Thus taking the pyramid of the beryl crystal, and using Miller's symbols, we have the axes and faces numbered as in figs. 8 and 9.

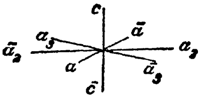

FIG. 8.

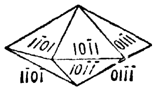

• FIG. 9.

The axial ratios once determined, it is possible from them and the symmetry to say at once what forms are possible, and to calculate their interfacial angles, &c.; but what forms will actually occur, under any conditions, cannot be predicted; their existence depends on external conditions, as presence of impurities in the solution, nature of the solvent, temperature, and speed of growth. Mineralogists and crystallographers often pay too much attention to the finding of new or numerous forms upon specimens without attempting to determine what were the conditions necessary for the production of these forms, which is the only point of real interest.

The following may serve as an example of the way in which the symmetry of a crystal determines the number and position of the faces of a form. In fig. 10 the three similar crystallographic axes of the beryl crystal (fig. 5) are represented by the lines a_1, a_2, and a_3, while the principal axis *c* is perpendicular to the plane of the paper. Suppose a face of the hexagonal pyramid to be present in the front, upper, middle segment, *i.e.* $10\bar{1}1$, then this demands the existence of a face $1\bar{1}01$, because the plane passing through axis a_1 and the vertical axis *c* is a plane of symmetry; the presence of $1\bar{1}01$ demands the existence of $0\bar{1}11$, because the plane containing a_2 and *c* is a plane of symmetry; further, these three faces demand the existence of other three, viz. 0111, $\bar{1}101$, $\bar{1}011$, because the plane a_3c is a plane of symmetry; and lastly, these six planes demand the presence of other six on the under part of the crystal, viz. $10\bar{1}\bar{1}$, 0111, 1101, $\bar{1}01\bar{1}$, $0\bar{1}1\bar{1}$, $1\bar{1}01$, because the plane containing axes a_1, a_2, a_3 is a plane of symmetry. And with these twelve faces the form is complete, for the other three planes of symmetry belonging to this system are already satisfied.

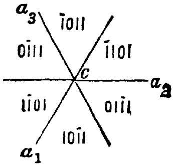

FIG. 10.

It would be very tedious and redundant to denote this or any other form by writing the symbols of all its faces, and it is therefore customary to write the symbols of only one, generally one in the front, upper, right corner, and to inclose it in brackets thus $(10\bar{1}1)$ for the pyramid in question. The general shape of a form is not essentially altered by varying the indices within certain limits; thus $(30\bar{3}1)$ and $(10\bar{1}3)$ (figs. 11 and 12) as well as $(10\bar{1}1)$ (fig. 9), represent hexagonal pyramids, though the form $(30\bar{3}1)$ is very high and pointed, while the form $(10\bar{1}3)$ is proportionally low and flat-looking. These may all be expressed by one general symbol $(m0\bar{m}1)$ (where *m* has any value *between* 0 and ∞), and are said to be particular forms of one general form $(m0\bar{m}1)$; thus fig. 12 represents the particular form for a crystal of beryl when $m = \frac{1}{3}$, for $10\bar{1}3$ is the same as $\frac{1}{3}0\bar{\frac{1}{3}}$, *i.e.* $m0\bar{m}1$.

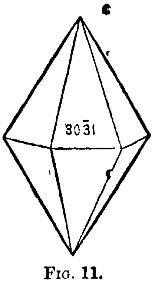

FIG. 11.

FIG. 12.

But if the index *m* has the value of 0, then the six upper faces of the pyramid fall together into one plane, and so also do the six lower faces, so that the form (0001) consists only of two faces parallel to each other and also to the plane of principal symmetry; if *m* has the value of ∞, then each of the upper six faces becomes coincident with the subjacent bottom face, and the form $(\infty 0 \bar{\infty} 1)$, or, as it is more usually written, $(10\bar{1}0)$, consists of six faces, all parallel to the axis of principal symmetry, and consequently not limited towards either end; these two forms (0001) the basal plane, and $(10\bar{1}0)$ the prism, may be called open forms, and can never occur alone on a crystal. They contain no variable quantity, and may therefore be called *fixed forms*, while the pyramid is a *variable form*.

These two forms, the basal plane and the prism, though derivable from the pyramid and related to it in position, are obviously quite distinct forms, and all are so far independent of each other that any one may or may not occur on a crystal in conjunction with the others. By varying the indices in every possible manner, as just indicated, it is easy to determine the shapes

,nd number of all such fundamental or general orms for every system; and indeed it is only ossible to grasp the relationships existing beween them by regarding them as being derived rom one perfectly general form $(mn1)$. The umber of individual forms is very limited; the ollowing is a complete list of their symbols and ames.

Regular system.—$(mn1)$, $(mm1)$, $(mn0)$, $mm0)$, (111), (001), (110), called respectively *exakis octahedron*, *triakis octahedron*, *tetrakis exahedron*, *trapezohedron*, *octahedron*, *cube* or *exahedron*, and *dodekahedron*; the last three re fixed forms.

Hexagonal system.—$(m\bar{p}\bar{n}1)$, (*Note*: in the ymbols for all hexagonal forms $m+n+p=0$). $m\bar{p}\bar{n}0)$, in both these cases the ratio $\frac{m}{n}$ varies nly between 1 and 2; $(m0\bar{m}1)$, $(10\bar{1}0)$, $(2m\bar{m}\bar{m}1)$, $2\bar{1}\bar{1}0)$, and (0001), called respectively the *diexagonal pyramid* and *prism*, the *hexagonal yramids* and *prisms of the first order*, and *of he second order*, and the *basal plane*.

Quadratic system.—$(mn1)$ and $(mn0)$, where the ratio $\frac{m}{n}$ varies *between* 1 and ∞; $mm1)$, $(mm0)$, $(m01)$, $(m00)$, and 001; the orms are called the *diquadratic pyramid* nd *prism*, the *quadratic pyramid* and *prisms f the first order*, and *of the second order*, and the *basal plane*.

Rhombic system.—$(mn1)$, $(mn0)$, (001), called respectively *pyramids prisms* or *domes*, and *basal plane* or *pinacoids*.

Monoclinic system.—The same forms exist as in the rhombic system, but here, owing to low order of symmetry, all the pyramids and some of the domes are composed of independent halves, which are distinguished as + or −, or by more fully denoting the position of the face; thus $(mn1)$ and $(mn\bar{1})$.

Asymmetric system.—The same forms exist as in the rhombic system, but here, owing to the lack of symmetry, all the pyramids are composed of independent quarters, thus $(mn1)$, $(m\bar{n}1)$, $(mn1)$, and $(m\bar{n}\bar{1})$, and all the prisms and domes are composed of independent halves, thus $(mn0)$ and $(m\bar{n}0)$.

The forms just described are collectively called *holohedral* or whole or complete-faced forms, to distinguish them from other forms known as *hemihedral* or half-faced, and *tetartohedral* or quarter-faced.

Hemihedral forms may be considered as derived from the holohedral forms by resolving these by a set or sets of planes of symmetry into a number of equal segments, when the faces contained in any one segment belong to the one hemihedral form, while those contained in the adjacent segment or segments belong to the other hemihedral form, and so on all round the crystal.

The hemihedral forms of the hexagonal system being very important will be taken by way of example. Any holohedral hexagonal form may be divided into segments in three different ways:—

Firstly, by the plane of principal symmetry and one of the two sets of three planes of ordinary symmetry; making then the adjacent faces independent, the *rhombohedral hemihedral* forms are produced. Numbering the faces of the most general form, the dihexagonal prism, as in fig. 13 it is seen that the faces are divided thus:

1 2 3 4 5 6 7 8 9 10 11 12
1 2 3 4 5 6 7 8 9 10 11 12

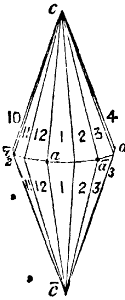

Fig. 13.

The two forms

1 2 . . 5 6 . . 9 10 . .
. . 3 4 . . 7 8 . . 11 12

and

. . 3 4 . . 7 8 . . 11 12
1 2 . . 5 6 . . 9 10 . .

are known as the + and − *scalenohedrons* (figs. 14 and 15), which differ from each other in position and in physical properties. Just as in the holohedral division, so here, the indices of only one face is written within brackets to denote the whole form, but to distinguish it from the symbol of the original pyramid the prefix κ is added; thus the symbols for the two scalenohedrons are $\kappa(m\bar{p}\bar{n}1)$ and $\kappa(pn\bar{m}1)$. By varying the values of these indices m, n, p in every possible way, or by dividing all the other holohedral forms into segments in the same fashion, it is found that there are produced two other new forms, the + and − *rhombohedrons* $\kappa(m0\bar{m}1)$ and $\kappa(0m\bar{m}1)$, figs. 16 and 17; while the following forms already mentioned in the holohedral division appear again without apparent alteration, viz. $(m\bar{p}\bar{n}0)$, $(10\bar{1}0)$, $(2m\bar{m}\bar{m}1)$, $(2\bar{1}\bar{1}0)$, and (0001). But the con-

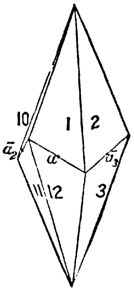

Fig. 14.

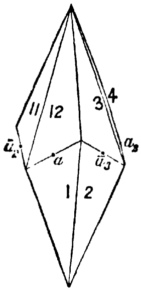

Fig. 15.

stancy of these latter forms in both divisions is not real, as the physical properties are different; this is especially to be seen in the manner in which they yield to the action of solvents, whereby little pittings or *etch-figures* are produced which vary in their symmetry according as the forms are holohedral or hemihedral. It

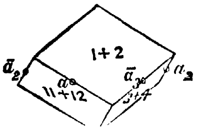

FIG. 16.

is to be understood that practically the holohedral and hemihedral forms are perfectly distinct, that is, a given substance shows the forms of only one of the two classes, never those of the other. For example, calcite frequently occurs in the form of the scalenohedron (3$\bar{1}\bar{2}$1), fig. 14, and is therefore obviously hemimorphous, but it also frequently occurs in the form of fig. 18, and

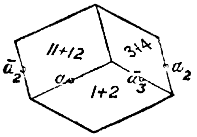

FIG. 17.

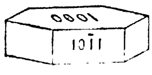

FIG. 18.

this may be either a holohedral or a hemihedral crystal, but the fact that such crystals cleave with the utmost readiness parallel to the faces of the positive rhombohedron $\kappa\,(m0\bar{m}1)$ at once removes it from the class of holohedral crystals; its hemimorphous nature is also proved by other physical properties.

A holohedral hexagonal form may be divided into segments, *secondly*, by means of the two sets of three planes of ordinary symmetry, whereby the *pyramidal hemihedral forms* are produced; for example:—

~~1~~ 2 ~~3~~ 4 ~~5~~ 6 ~~7~~ 8 ~~9~~ 10 ~~11~~ 12
~~1~~ 2 ~~3~~ 4 ~~5~~ 6 ~~7~~ 8 ~~9~~ 10 ~~11~~ 12

The uncrossed faces $\pi(pn\bar{m}1)$ are represented on a crystal of apatite by figure 19 where $\pi(pn\bar{m}1) = \pi(21\bar{3}1)$. All other forms are exter-

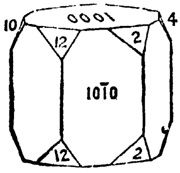

FIG. 19.

nally the same as in the holohedral division, with the exception of $\pi(pn\bar{m}0)$. These two new forms are called the pyramid and prism of the third order.

Thirdly, by means of the two sets of three planes of ordinary symmetry and the plane of principal symmetry, whereby the *trapezohedral hemihedral* forms are produced; for example:—

~~1~~ 2 ~~3~~ 4 ~~5~~ 6 ~~7~~ 8 ~~9~~ 10 ~~11~~ 12
1 ~~2~~ 3 ~~4~~ 5 ~~6~~ 7 ~~8~~ 9 ~~10~~ 11 ~~12~~.

These forms are distinguished by the prefix τ, the crossed faces being $\tau(m\bar{p}\bar{n}1)$; such forms have not been actually observed.

The *tetartohedral forms* before referred to may be considered as being produced by the superposition of two different hemihedræ upon the same crystal. As there are in the hexagonal system three classes of hemihedrie, there can be obtained two or perhaps three different classes of tetartohedrie. In the following schemes the faces suppressed by the rhombohedral, pyramidal, and trapezohedral, hemihedræ are respectively crossed /, —, or \\.

First, the *rhombohedral tetartohedrie* is produced thus:—

~~1~~ ~~2~~ ~~3~~ 4 ~~5~~ ~~6~~ ~~7~~ 8 ~~9~~ ~~10~~ ~~11~~ 12
~~1~~ 2 ~~3~~ ~~4~~ ~~5~~ 6 ~~7~~ ~~8~~ ~~9~~ 10 ~~11~~ ~~12~~.

The faces of a dihexagonal pyramid remaining uncrossed, viz. $_2{}^4{}_8{}^8{}_{10}{}^{12}$, form a rhombohedron of the third order, written $\kappa\pi(m\bar{n}\bar{p}1)$, which is exhibited in fig. 20 of a copper silicate (diaspore) crystal, where the indices are $\kappa\pi(14.\bar{1}\bar{3}.\bar{1}.6)$.

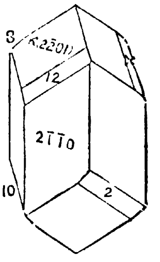

FIG. 20.

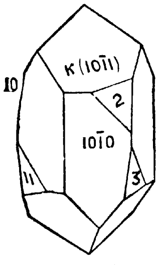

FIG. 21.

Secondly, the *trapezohedral tetartohedrie* is produced thus:—

~~1~~ 2 ~~3~~ ~~4~~ ~~5~~ 6 ~~7~~ ~~8~~ ~~9~~ 10 ~~11~~ ~~12~~
~~1~~ ~~2~~ 3 ~~4~~ ~~5~~ ~~6~~ 7 ~~8~~ ~~9~~ ~~10~~ 11 ~~12~~,

the form $\kappa\tau(np\bar{m}1)$ consisting of the six uncrossed faces $^2{}_3{}^6{}_7{}^{10}{}_{11}$ being known as the trigonal trapezohedron, and in the figure representing a quartz crystal the faces of such a form, viz. $\kappa\tau(5\bar{1}\bar{6}1)$ are shown (fig. 21).

Thirdly, the scheme

~~1~~ 2 ~~3~~ 4 ~~5~~ 6 ~~7~~ 8 ~~9~~ 10 ~~11~~ 12
~~1~~ ~~2~~ ~~3~~ ~~4~~ ~~5~~ ~~6~~ ~~7~~ ~~8~~ ~~9~~ ~~10~~ ~~11~~ ~~12~~

shows a form bounded by six faces meeting the vertical axis above, but no face meeting it below. It is doubtful whether this tetartohedrie has been observed; for exactly the same form would be produced by making either of the forms $\pi(m\bar{p}\bar{n}1)$ or $\tau(m\bar{p}\bar{n}1)$ hemimorphous or half sided.

Hemimorphism may be described as the dividing of the faces of a crystalline form into two independent halves, the one half cutting the one extremity of an axis of symmetry, and the other half the other extremity of the same axis. Hemimorphism is to be found in the first five systems i holohedral, hemihedral, and tetartohedral, divisions alike; it is supposed to be due to asymmetry of the atoms in the molecule, and the solutions of the substances showing this phenomenon, as tartaric acid, milk, sugar, &c., are generally optically active. It is to be noticed that some divisions of crystals are necessarily hemimorphous. Thus the hexagonal trapezohedral tetartohedral forms are hemimorphous to the axes of ordinary symmetry.

The hexagonal crystals are thus divided into the following six or seven distinct classes: (*a*) holohedral; (*b*) hemihedral, and that of three kinds, rhombohedral, pyramidal, and trapezohedral; and (*c*) tetartohedral, and that of at least two kinds, rhombohedral and trapezohedral, and possibly another; and lastly to each of these six classes there may or may not be assimilated also hemimorphism, making in all twelve or possibly thirteen divisions of hexagonal crystals, in only one of which can any substance ever crystallise.

These six or seven classes are to be considered as being due to the different arrangements of the molecules in the crystal, but among these different molecular arrangements there are certain regularities common which group them all together into one general system. It is to be noted that all hemihedral and tetartohedral divisions are invariably possessed of fewer planes of symmetry or of planes of a lower degree of symmetry than are the holohedral forms; thus the trapezohedral hemihedral forms and all tetartohedral forms of the hexagonal system are possessed of no plane of symmetry whatever, *i.e.* as defined at the commencement of this article; but such forms do not, therefore, belong to the asymmetric system, for in the first place they show a perfect regularity in the recurrence of equal faces and angles in sets of three or of six, which an asymmetric crystal can never do, and secondly they show none of the physical properties of these crystals, but properties that are either identical with those of the hexagonal holohedral crystals, or are in the main of the same kind, differing only just so much as might be expected from the lower degree of symmetry they possess.

Just as hexagonal crystals are divided into a number of distinct classes, so also are the crystals of the other systems as far as their varying symmetry allows. Thus regular crystals are either (*a*) holohedral, (*b*) hemihedral, and that of three kinds, viz. tetrahedral, pentagonal, or plagihedral, or (*c*) tetartohedral of one kind only; the quadratic crystals are subdivided exactly like the hexagonal ones; the rhombic crystals are either (*a*) holohedral or (*b*) hemihedral; and the monosymmetric and asymmetric crystals can show neither hemihedrie nor tetartohedrie.

There still remains another regularity met with in the forms of crystals, viz. the symmetrical growth of two or more crystals as one individual. Such a complex is called a *twin* or *trilling*, and in such the component individuals are definitely related as regards position, viz. the one crystal generally occupies such a position that were it rotated through 180° about a particular line, called the *twin axis*, all its faces &c. would then be exactly parallel to those of other crystals. The plane at right angles to the twin axis is called the *twin plane*, and in many instances the two individuals meet in this plane, and it is then also termed the *contact plane*; but in other instances the two individuals penetrate each other in a perfectly irregular manner, and there is then no definite contact-plane. The formation of a twin crystal is probably explained by extreme viscosity of the solvent, or of an insufficient lapse of time between the separation of two molecules from a solution and their approximation to form a single solid particle, and for either of which reasons the molecules would not be able to become exactly parallel, which must be the most stable position, but would take up the next most stable position by reason of the molecule being originally more nearly in that position. As a plane of symmetry for the external form is also a plane of symmetry of the intermolecular force, which varies with the direction in which it is exercised, so a plane of symmetry can never be a twin plane, else the two individuals would be exactly parallel; that is, they would be identical: further, as the arrangement of the molecules, and consequently the external form, depends on this same intermolecular force, so the twin plane and axis are invariably connected with the external form; generally the twin plane is a possible crystalline face, and often one that is expressed by a very simple symbol. Twin or complex crystals are often characterised by re-entering angles, but these are frequently either so small as to be unnoticeable or are not present, and the crystal then affects a symmetry that it does not really possess.

The following figs. represent rhombic aragonite crystals; fig. 22, a simple crystal, and fig. 23, a twin, showing re-entering angles, the twin plane being the prism face; and lastly, fig. 24 represents a trilling, showing only the forms (110) and (001), which externally appears very like a hexagonal crystal, except that two of the vertical faces are a little nicked because the angle of the prism (110) is not exactly 120°. The real nature of such compound crystals is most easily detected by their optical properties, a section cut parallel to the base at once resolving itself in a parallel beam of polarised light into a number of segments distinguished from each other by difference of colour or luminosity, and whose relative positions can readily be determined by optical examination.

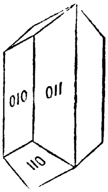

FIG. 22.

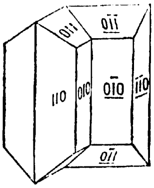

FIG. 23.

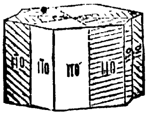

FIG. 24.

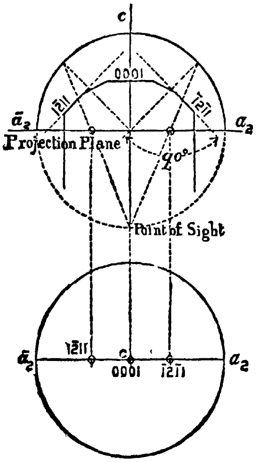
Besides representing the form of crystals by parallel projections, as in the various figures, these forms are often also represented in a totally different manner, viz. by spherical projection. From a central point within a crystal, imagine a sphere of any radius described, and from its centre a line let fall perpendicularly on to every crystalline face and produced until it cuts the surface of the sphere. The positions of the faces are thus recorded by as many points upon the surface of the sphere, and their positions may very conveniently be represented upon a flat surface by making a diametral section of the sphere bringing the recording plane and one extremity of the diameter at right angles to that plane into the point of view, whereby great labour in drawing and calculating is saved, as all great circles on the sphere appear in the projection as straight lines or as arcs of circles. In the regular, hexagonal, and quadratic, systems the diametral section is always drawn parallel to the plane of principal symmetry, in the rhombic system to the basal plane, in the monosymmetric and asymmetric systems it is drawn perpendicular to the faces of the prisms. Thus the beryl crystal, fig. 5, as far as the sphere lies in the plane of this paper, appears as in fig. 25, and the position of the three faces, when drawn upon the plane of principal symmetry, as in fig. 26; the one straight line joining the three points shows that they are in the same zone, that is, are all parallel to one common direction, and therefore their intersecting edges are parallel, and this fact is very easily noticed or tested when the crystal is mounted on the goniometer for measuring. The completed projection appears as in fig. 27, where zones are all indicated by the various lines circular or straight. This method of projection also allows of the positions of optical axes, cleavage planes, &c., being shown.



Figs. 25 and 26.

It now only remains to mention a few points concerning the growth and actual appearance of the faces of a crystal, beyond those mentioned on p. 278. A crystal once formed in a solution and continuing to increase in size, every face, or at least every face of any set of faces, would receive a deposit of the same thickness, and an ideally perfect crystal as represented in the figures would result, were it not that the liquid in depositing the solid substance altered its specific gravity, and currents being thus generated different parts of the crystal are thus subjected to different conditions, and the several faces receive unequal deposits of new material. In consequence, the intersections of the similar faces and their superficial extent are often very dissimilar, though every face always remains exactly parallel to its original position, and the interfacial angles are constant. This so-called *distortion* is often brought about or increased by the crystal becoming attached by an end or side to other crystals, or to the containing vessel. Thus fig. 28 represents an alum crystal that has lain on the flat bottom of the containing vessel, and fig. 29 represents the ideal form such as may be obtained by constantly changing the position of the growing crystal.

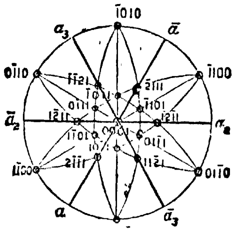


Fig. 27.

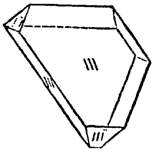

Fig. 28.

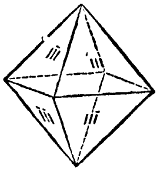

Fig. 29.

When new material is very quickly presented to a growing crystal, it is often noticed that the acuter solid angles grow extremely rapidly, shooting out into long needle-like points, and often other acicular points will start from along the first, and thus fern-like forms are produced; all such growths are termed *crystalline skeletons*; when the rate of deposit becomes less the needles almost cease to grow in the direction of their length, but increase continually in breadth and thickness until they touch each other, and the crystal returns to its original appearance, though almost invariably it will contain a great number of larger or smaller cavities, filled with the mother-liquor, and, as already mentioned, these cavities exhibit an arrangement or a form that corresponds with the general symmetry of the crystal. Some substances, as ammonium chloride, metallic silver, &c., are very prone to form such *dendritic forms*, while with other substances, as platinum-potassium chloride, if existing crystals were not able to take up the new material, a multitude of minute crystals would at once form. The direction of these skeleton arms is always coincident with some crystallographic direction, and they are in reality made up of numerous crystals, in exactly parallel position. It has been mentioned that the faces of crystals are often striated; the striæ consist of numerous alternating faces of one or more forms; thus nitre crystals are vertically striated on the prism and pinacoid faces by reason of these faces being repeated alternately very many times.

Finally it may be useful briefly to describe such a microscope as is used for the examination of minute or growing crystals, or for the examination of rock sections. In this connexion reference should be made to the papers of Behrens (*Royal Micros. Soc. Journ.*, 1882) and others, on the microchemical reactions by which minute fragments of minerals &c. may be analysed qualitatively by converting their constituents into crystalline precipitates that may be recognised under the microscope. The essential parts of the microscope are the same as in every other instrument, the parts specially concerned in crystallographic work being the following. The stage can be rotated freely about the optical centre of the instrument, and is brought exactly into that position by a couple of adjusting screws; the circumference is graduated into degrees, and fractions can be read by a vernier. The eye-pieces contain crossed (rectangular) threads, and these always occupy a fixed position by reason of a pin in the eye-piece and a notch in the outer tube. Plane angles of crystals that lie suitably, the angles between the lines of inclosures &c., are easily measured by the rotating stage and the cross of the eye-piece. The fine adjustment-screw for focussing is of known pitch, and is provided with a head divided on its circumference. By using a high power and a rather thick specimen it is easy to determine the refractive index not only of solids but of liquids (Sorby). In the eye-piece can be fitted a micrometer scale, and by using this and the micrometer screw the interfacial angles of minute crystals can be measured, though the method is one that would only be used if the goniometric measurement were not possible. During the cutting or grinding of sections, especially rock sections, the crystals often cleave, and the positions of the planes of cleavage are at once determined from the fine parallel hair-like cracks in the specimen. Underneath the stage a polarising prism is quickly put into position so that its polarising plane is parallel to one of the cross threads in the eye-piece; crystals may then be examined for dichroïsm. Above the stage, and most conveniently over the eye-piece, a second polarising prism may be placed or rapidly removed; it may be rotated about the central axis, and the amount of rotation is approximately shown on a small divided circle. When the two prisms are crossed, isotropic and anisotropic crystals are at once distinguished, unless the crystalline plate is at right angles to the optical axis, but in this case the interference figure can be obtained as described below; further, if the crystal be anisotropic, twinning is generally at once recognised, and, with the help of the rotating stage, the relationships of the different parts are determined, by comparing the depolarising directions among themselves and with the edges of the crystal; similarly in a simple anisotropic crystal the angles between the depolarising directions and the edges may be measured, and the system of crystallisation thus determined when the examination of the external form alone would not have been conclusive; and even when the external form has been destroyed, or when it has been lost by reason of the crystal growing until it filled the whole space that happened to be at its disposal, the examination of the cleavage cracks, lines of inclosures, and depolarising directions, is often sufficient to determine the crystalline system. The relationship between depolarising directions and edges may be used for discriminating between different substances crystallising in the monosymmetric or asymmetric systems, as the various felspars. Finally anisotropic crystals lying in suitable positions can be examined for their interference figures by removing the eye-piece, but retaining both polarising prisms, placing a small, very short, focus-lens above the lower prism and directly below, but quite close to, the crystal, and lastly using a short focus objective and bringing it down rather close to the specimen. The interference figures thus observed are certainly very small, and an extra lens is sometimes inserted above the objective to magnify them, but the angle of view is thereby diminished. Uniaxial and biaxial crystals are thus at once distinguished, and if the former show any marked amount of circular polarisation, or the latter any marked amount of dispersion for the various colours, these phenomena can also be noticed, especially if use is made of red and blue glasses to simplify the phenomena; such glasses are also used in the measurement of the angles between depolarising directions and crystalline edges. H. B.

CUBEBS.—The fruit of *Piper Cubeba*, a native of Java. It contains a volatile oil (from which 'camphor of cubebs' may be separated), a crystalline substance cubebin, an acid resin cubebic acid, and an indifferent resin (Monheim, *J. chim. Méd.* 11, 352; Blanchet a. Sell, *A.* 6, 294; Müller, *A.* 2, 90; Winckler, *A.* 8, 203; Soubeiran a. Capitaine, *A.* 31, 190; 34, 311; *J. Ph.* 26, 75; Aubergier, *Rev. Scient.* 4, 220; Schmidt, *Ar. Ph.* [2] 191, 1; Schaer a. Wyss, *Ar. Ph.* [3] 6, 316; Oglialoro, *G.* 5, 467).

Oil of Cubebs. Contains dipentinene, the hydrochloride of which $C_{10}H_{16}2HCl$ melts at 49°, but consists chiefly of hydrocarbons boiling between 250° and 270°, amongst which is a sesquiterpene $C_{15}H_{24}$ (275°). V.D. 6·73 (calc. 7·05), whose hydrochloride $C_{15}H_{24}2HCl$ melts at [118°] (Wallach, *A.* 238, 80) or [131°] (S. a. C.).

Camphor of Cubebs $C_{15}H_{26}O$. [67°]. (148°). Occurs only in old cubebs. Trimetric crystals (from alcohol-ether). Lævorotatory. At 230° it is split up into water and **cubebene** $C_{15}H_{24}$ (Schmidt, *B.* 10, 189; *cf.* Berthelot, *Bl.* [2] 11, 3).

Cubebin $C_{10}H_{10}O_3$

i.e.
$\left[\begin{smallmatrix}3 & 1\\ 4 & \end{smallmatrix}\right] CH_2{<}\begin{smallmatrix}O\\O\end{smallmatrix}{>}C_6H_3(C_3H_5O)$? [125°]. S. (alcohol) 1·31 at 12°. S. (ether) 3·75. Extracted by alcohol from cubebs after removal of the

essential oil by steam distillation (Schuck, *N. Repert. Pharm.* 1, 213; Steer, *A.* 36, 331; Weidel, *Sits. W.* 74 [2] 377; Schär, *Ar. Ph.* [3] 25, 531).

Properties.—Small needles (from alcohol); v. sl. sol. water. Conc. H_2SO_4 colours it crimson. HCl and HI have no action on it.

Reactions.—1. $KMnO_4$ on warming oxidises it to oxalic acid and a resin, from which, after extracting with $CHCl_3$, a crystalline residue of piperonylic acid $C_8H_6O_4$ [228°] is obtained.—2. When heated with *acetic anhydride* and *sodium acetate* to 140° C. it yields $C_{20}H_{18}O_5$ [78°], which can be obtained pure by crystallisation from alcohol (Pomeranz, *M.* 8, 466).—3. *Potash-fusion* gives CO_2, HOAc, and protocatechuic acid.—4. HNO_3 gives oxalic and picric acids.—5. *Nitrous acid* gives yellow crystals of nitro-cubebin $C_{10}H_9(NO_2)O_3$, which dissolves in aqueous KOH, forming a violet solution.—6. Br, added to a solution of cubebin in chloroform, gives $C_{10}H_7Br_3O_2$, which separates from boiling xylene in white crystals.

Benzoyl derivative $C_{10}H_9BzO_3$. [147°] (Pomeranz, *M.* 9, 323).

Cubebic acid $C_{14}H_{16}O_4$ (Schulze, *Ar. Ph.* [3] 2, 388); $C_{13}H_{14}O_7$ (Schmidt, *Ar. Ph.* [2] 191, 1). A resinous acid extracted from cubebs by ether, freed from volatile oil by steam-distillation, and purified by re-crystallisation of its Ba salt (Bernazik, *C. C.* 1864, 191). Amorphous, insol. water and acids, v. sol. alcohol, ether, and alkalis.

CUDBEAR. A name given to a variety of archil, being also prepared from lichens, chiefly of the genus *Lecanora*.

CUMALIC ACID *v.* COUMALIC ACID.

CUMARHYDRIN *v.* COTO BARK.

ψ-CUMENE $C_6H_3(CH_3)_3$ [1:3:4]. *i-Tri-methyl-benzene.* Mol. w. 120. (169½° i.V.) (Jacobsen, *B.* 19, 2513). S.G. $\frac{0}{}$ ·8043; $\frac{20}{}$ ·8530. H.F.p. 1810. H.F.v. −1590 (*Th.*). *Dielectric constant* 2·431 at 14° (Negreano, *C. R.* 104, 423). μ_D 1·484. Occurs in all kinds of petroleum (American, Russian, &c.) (Engler, *B.* 18, 2234; *cf.* Mansfield, *C. J.* 1, 244; *A.* 69, 179; Ritthausen, *J. pr.* 61, 79; Beilstein a. Kögler, *A.* 137, 317).

Formation.—1. From bromo-*m*-xylene and bromo-*p*-xylene by treatment with MeI and sodium (Fittig, *A.* 139, 187; 151, 257, 286).—2. From di-bromo-toluene, MeI, and sodium (Jannasch, *A.* 176, 286).—3. From phorone (derived from acetone) by treatment with P_2O_5 (Jacobsen, *B.* 10, 855).—4. From toluene, MeCl, and Al_2Cl_6 (Friedel a. Crafts, *A. Ch.* [6] 1, 461). 5. By boiling pseudo-cumyl-hydrazine with aqueous $CuSO_4$ (Haller, *B.* 18, 92).

Preparation.—The mixture of ψ-cumene and mesitylene obtained by the distillation of coal tar is sulphonated by agitation with cold conc. H_2SO_4; on adding water a portion of the ψ-cumene sulphonic acid is ppd., the remaining acids are converted successively into their Ba salts, chlorides, and amides, and the latter are separated by crystallisation from alcohol, in which the amide of ψ-cumene sulphonic acid is sparingly soluble. The sulphamide is then converted into ψ-cumene by heating with fuming aqueous HCl at 175° (Jacobsen, *B.* 9, 256). The sulphonic acids of ψ-cumene and mesitylene may also be separated by heating with HClAq at 100° for one hour, when the latter only undergoes hydrolysis (Armstrong, *B.* 11, 1697). ψ-Cumene sulphonic acid is decomposed by distillation with dilute H_2SO_4 in a current of steam, hydrolysis beginning at 115° (Armstrong a. Miller, *C. J.* 45, 148).

Reactions.—1. Readily attacked by halogens. In the *dark* 1 mol. of bromine produces mono-(eso)-bromo-pseudo-cumene $C_6H_2Me_3Br$ [73°]; further bromination yields di- and tri-(eso)-bromo-pseudo-cumene (C_6HMe_3Br and $C_6Me_3Br_3$) of melting-points [61°] and [226°] respectively. Direct *sunshine* acts like *heat*, causing the substitution to take place in the CH_3 groups; 1 mol. Br produces a liquid ω-bromo-(pseudo)-cumene (pseudo-cumyl bromide) $C_6H_3(CH_3)_2.CH_2Br$; 2 mols. bromine produce $\omega_1{,}\omega_2$-di-bromo-pseudo-cumene $C_6H_3(CH_3)(CH_2Br)_2$ which melts at 97° (Schramm, *B.* 19, 216).—2. Converted by boiling with Al_2Cl_6 into toluene, *m*-xylene, a little *p*-xylene, mesitylene, durene, and isodurene (Anschütz, *A.* 235, 186).—3. *Methylene chloride* and Al_2Cl_6 give durene, tetra-methyl-anthracene [c. 163°], hexa-methyl-anthracene [c. 220°] and $C_{18}H_{18}$ [c. 290°] (Friedel a. Crafts, *A. Ch.* [6] 11, 263).—4. Gives a tri-nitro- derivative [185°].—5. Dilute HNO_3 gives two di-methyl-benzoic acids and a little $C_6H_3Me(CO_2H)_2$.

ψ-Cumene hexahydride C_9H_{18}. (137°). S.G. $\frac{0}{0}$ ·7812; $\frac{20}{0}$ ·7667. From ψ-cumene, HI, and P. HNO_3 gives tri-nitro-ψ-cumene. Br and Al_2Br_6 give tri-bromo-ψ-cumene (Konovaloff, *C.C.* 1887, 1133). Probably identical with nonaphthene.

Cumene C_9H_{12} *i.e.* C_6H_5Pr. *Isopropyl-benzene.* Mol. w. 120. (153° i.V.). S.G. $\frac{0}{}$ ·8776; $\frac{22}{}$ ·8577 (Silva, *Bl.* [2] 43, 317); $\frac{0}{}$ ·8798; $\frac{25}{}$ ·8587 (Paternò a. Pisati, *G.* 3, 574).

Formation.—1. By distilling cuminic acid with baryta or lime (Gerhardt a. Cahours, *A. Ch.* [3] 1, 87, 372; 14, 107; *A.* 38, 88; *cf. A.* 220, 27).—2. From isopropyl bromide, benzene, and Al_2Br_6 (Gustavson, *B.* 11, 1251; R. Meyer, *J. pr.* [2] 34, 98). In the same way from *n*-propyl bromide, inasmuch as *n*-propyl bromide is converted by heating with Al_2Br_6 into isopropyl-bromide (Kekulé a. Schrötter, *B.* 12, 2280).—3. By acting with isopropyl chloride or *n*-propyl chloride on benzene in presence of aluminium chloride (Silva; Claus a. Schulte, *B.* 19, 3012).—4. As a by-product by the action of allyl chloride on benzene in presence of Al_2Cl_6.—5. By the action of di-chloro-acetone in presence of Al_2Cl_6 on benzene as a by-product (Silva).—6. From benzylidene chloride and $ZnMe_2$ (Liebmann, *B.* 13, 45).—7. From iso-propyl iodide, bromo-benzene, and sodium (Jacobsen, *B.* 8, 1260).

Reactions.—1. *Chromic mixture* gives benzoic acid.—2. Br and Al_2Br_6 give C_6Br_6, isopropyl bromide, and tri-bromo-propane (c. 218°).

Cumene tetrahydride C_9H_{16}. (155°). Occurs in small quantity in oil of resin (Renard, *A. Ch.* [6] 1, 239).

Cumene hexahydride C_9H_{18}. (c. 149°). S.G. $\frac{22}{}$ ·787. Occurs in oil of resin (Renard, *A. Ch.* [6] 1, 229; *cf.* Pelletier a. Walter, *A. Ch.* [2] 67, 99).

***n*-Cumene** C_6H_5Pr. ***n*-Propyl-benzene.** (158·5°). S.G. $\frac{0}{}$ ·88 (Spica, *G.* 8, 408); $\frac{9.8}{4}$ ·8702 (Schiff). C.E. (9·8 to 158·5) ·001184. V.D. 4·14 (for 4·14). S.V. 161·8 (Schiff, *A.* 220, 93).

Formation.—1. From *n*-propyl bromide, bromo-benzene, and sodium (Fittig, Schäffer a. König, *A.* 149, 324).—2. From benzyl chloride and $ZnEt_2$ (Paternò a. Spica, *G.* 7, 21).—3. From Al_2Cl_6, benzene and allyl chloride (Wispek a. Zuber, *A.* 218, 378); according to Silva (*Bl.* [2] 43, 318) the product is isopropyl-benzene.—4. A product of the action of ethylidene chloride on toluene in presence of Al_2Cl_6 (Anschütz a. Romig, *B.* 18, 665).

Reactions.—1. In CS_2 solution it combines with CrO_2Cl_2, forming a chocolate pp. $PhPr2CrO_2Cl_2$ converted by water into phenyl-propionic aldehyde (Étard, *A. Ch.* [5] 22, 252).—2. *Chromic* mixture gives benzoic acid.—3. By the action of *bromine* (1 mol.) in the dark or in presence of 3 p.c. of iodine in diffused daylight, a mixture of *o*- and *p*-bromo-propyl-benzene $C_6H_4Br(C_3H_7)$ is obtained. By the action of bromine (1 or 2 mols.) in direct sunshine, the side chain is substituted in the β-position giving $C_6H_5.CHBr.CH_2.CH_3$ or $C_6H_5.CBr_2.CH_2.CH_3$. If the β-mono-bromo-propyl-benzene is treated at 100° in the dark with another mol. of bromine, αβ-di-bromo-propyl-benzene is produced $C_6H_5.CHBr.CHBr.CH_3$ [65·5°] (Schramm, *B.* 18, 1274).

References.—Bromo-cumene, Chloro-cumene, Nitro-cumene, &c. *V.* also Azo- and Hydrazo-compounds.

ψ-CUMENE CARBOXYLIC ACID *v.* Cuminic acid.

ψ-CUMENE-SULPHONIC ACID $C_6H_2Me_3(SO_3H)$ [1:3:4:2]. Obtained by debromination of di bromo-pseudo-cumene-sulphonic acid $C_6Me_3Br_2(SO_3H)$ [1:3:4:5:6:2] by the action of zinc-dust and aqueous NH_3 upon the sodium salt. It is formed, together with the isomeride (1:3:4:5) and other products, by the prolonged action of conc. H_2SO_4 upon durene (*q.v.*) or its mono-sulphonic acid.—NaA′: very soluble small flat needles or plates.

Amide $C_6H_2Me_3(SO_2NH_2)$: [113°]; small flat needles or plates; v. e. sol. alcohol (Jacobsen, *B.* 19, 1222).

ψ-Cumene-sulphonic acid $C_6H_2Me_3(SO_3H)$ [1:3:4:5]. Obtained by debromination of bromo-pseudocumene-sulphonic acid by the action of zinc-dust and aqueous NH_3 upon the sodium salt (Jacobsen, *B.* 19, 1218), or by sodium-amalgam (Kelbe a. Pathe, *B.* 19, 1556). It is formed, together with the isomeride [1:3:4:2] and other products, by the prolonged action of conc. H_2SO_4 upon durene (*q. v.*) or its mono-sulphonic acid.

Salts.—NaA′aq: needles, v. sol. hot water.—KA′aq: similar to the preceding.—AgA′aq: sparingly soluble white plates.—BaA′aq: plates, sparingly sol. cold water (K. a. P.).—BaA'_2: thin prisms; sol. hot water, sl. sol. cold (J.).

Amide $C_6H_2Me_3(SO_2NH_2)$: [172°] (J.); [179°] (K. a. P.); needles or very small prisms; v. sol. alcohol.

ψ-Cumene sulphonic acid $C_6H_2Me_3SO_3H$ [1:2:4:5]. [112°]. Formed by dissolving ψ-cumene in conc. H_2SO_4 at 80°, and crystallised from dilute H_2SO_4 (Jacobsen, *A.* 184, 199). Cubes, sl. sol. dilute H_2SO_4. Converted by potash-fusion into $C_6H_2Me_2(OH)CO_2H$, whence, by distillation with lime, *m*-xylenol $C_6H_3Me_2(OH)$ [1:3:4] is got. Fusion of the K salt with sodium formate gives $C_6H_2Me_3.CO_2K$ (Reuter, *B.* 11, 29). By the action of bromine upon the aqueous solution 76 p.c. is converted into bromo-pseudo-cumene $C_6H_2Me_3Br$ [1:2:4:5], the remainder yielding bromo-pseudo-cumene-sulphonic acid $C_6HMe_3Br.SO_3H$ [1:2:4:3:5] (Kelbe a. Pathe, *B.* 19, 1546).

Salts.—NaA′ 5aq: transparent plates, loses 4aq in the air.—NaA′aq: white plates (from conc. solution).—KA′aq: sparingly soluble prisms.—AgA′aq: sparingly soluble needles.—BaA'_2. S. 4·5 at 11·5° (J.).—BaA'_2aq (Fittig a. Ernst, *A.* 139, 188).

Chloride $C_6H_2Me_3SO_2Cl$. [61°]. Monoclinic prisms (from ether).

Amide $C_6H_2Me_3SO_2NH_2$. [176°] (K. a. P.); [181°] (Jacobsen, *B.* 19, 2513). S. ·014 at 0°; ·26 at 100°. Large prisms, sol. hot, sl. sol. cold alcohol. Conc. HCl at 176° splits it up into NH_3, H_2SO_4, and ψ-cumene. Potassium permanganate gives $C_6H_2(CO_2H)Me_2(SO_2NH_2)$ [1:2:4:5], $C_6H_2(CO_2H)_2Me(SO_2NH_2)$ [1:4:2:5], and finally $C_6H_2(CO_2H)_3(SO_2NH_2)$ (Jacobsen a. H. Meyer, *B.* 16, 190). By heating with a small quantity of HCl there is formed $(C_6H_2Me_3SO_2)_2NH$ [177°], which is soluble in alkalis.

Cumene-(α)-sulphonic acid $C_6H_4(C_3H_7).SO_3H$. *Isopropyl-benzene sulphonic acid.* Formed in largest quantity by sulphonating cumene in the cold. By warming to 100°, or by several weeks' standing with the excess of H_2SO_4 it is in great part converted into the (β)-acid (Claus a. Tonn, *B.* 18, 1239). Small deliquescent scales. Potassium permanganate in presence of KOH forms $(CH_3)_2C(OH).C_6H_4.SO_3H$ (R. Meyer, *A.* 219, 300)

Salts.—KA′.—BaA'_2aq: laminæ. S. 4·6 at 16°, 5·6 at 60°, 50 at 100°.—PbA'_2aq: pearly scales.—CaA'_2 2aq.—SrA'_2 2aq. S. 100. On heating the solution saturated in the cold to 100° a crystalline pp. of SrA'_2 is formed.—MgA'_2 7aq.—AgA′.

Amide $C_6H_4Pr.SO_2NH_2$. [108°] (M.; Spica, *G.* 9, 433); [112°] (C. a. T.). Converted into *p*-oxy-benzoic acid by treatment with $KMnO_4$ and fusion of the product with potash.

Cumene-(β)-sulphonic acid $C_6H_4(C_3H_7)SO_3H$. Formed, together with a smaller quantity of the (α)-sulphonic acid, by heating cumene with an excess of ordinary H_2SO_4 on the water-bath (Claus a. Tonn, *B.* 18, 1239; Spica, *G.* 9, 433). Small needles. V. sol. water. By fusion with sodium formate it is converted into a cuminic acid which gives phthalic acid on oxidation (Claus a. Schulte, *B.* 19, 3012).

Salts.—A'_2Ba 3½aq: small needles; S. 20 at 16°; more soluble than the Ba salt of the preceding acid.—A'_2Pb 2aq: easily soluble microscopic needles.—A'_2Mg 8aq: soluble pearly plates.—A'_2Zn 7aq: easily soluble glistening needles.—A'_2Cu 8aq: easily soluble large green needles.

Chloride $C_9H_{11}.SO_2Cl$: yellow oil.

Amide $C_9H_{11}.SO_2NH_2$: [127° uncor.] (C. a. T.); [96°] (S.); glistening needles.

n-Cumene sulphonic acid $C_6H_4Pr.SO_3H$. From *n*-cumene and H_2SO_4. According to Paternò a. Spica (*G.* 8, 408) both the *o* and *p* acids are formed.

Salts.—KA′ ½aq (from alcohol).—CaA'_2.—BaA'_2 (Fittig, *A.* 149, 330).

Amide $C_6H_4Pr.SO_2NH_2$. [110°]. Scales (from water) (R. Meyer, *A.* 219, 299).

ψ-CUMENOL $C_6H_2(CH_3)_3OH$[5:4:2:1]. [72°]. (235°). H.F. p. 68,540 (Stohmann, *J. pr.* [2] 34, 318).

Formation.—1. Formed by diazotising ψ-cumidine [62°] and boiling the diazo- compound with water (Liebermann a. Kostanecki, *B.* 17, 885; Auwers, *B.* 17, 2976; Krohn, *B.* 21, 884). 2. By fusing ψ-cumene sulphonic acid with KOH (Reuter, *B.* 11, 29).

Properties.—Slender flexible needles, very volatile with steam. Insol. cold water. Fe_2Cl_6 does not colour its solutions. Gives a bromo-derivative [32°] and a di-bromo-derivative [150°].

Benzoyl derivative $C_6H_2Me_3(OBz)$. [63°]. H.F. 87,240 (Stohmann, *J. pr.* [2] 36, 8).

Methyl ether $C_6H_2(CH_3)_3OMe$. (214°) (H.); (211°) (Auwers, *B.* 18, 2657); colourless liquid. Formed by heating sulphate of diazo-pseudo-cumene with methyl-alcohol (Hofmann, *B.* 17, 1918).

Ethyl ether $C_6H_2(CH_3)_3OEt$: (224°); colourless liquid. Formed by heating sulphate of diazo-pseudo-cumene with ethyl-alcohol.

Isoamyl ether $C_6H_2(CH_3)_3OC_5H_{11}$: (265°).

Sulphate $C_6H_2Me_3(OSO_3H)$. From ψ-cumenol and H_2SO_4 (Reuter, *B.* 11, 29). Small crystals; decomposed by water into ψ-cumenol and H_2SO_4 even in the cold.—BaA'_2: slightly soluble leaflets.—KA′.—ZnA'_2.

ψ-Cumenol $C_6H_2Me_3(OH)$[1:3:4:2]. [62°]. (233°). Formed from pseudo-cumene-sulphonic acid (1:3:4:2) by KOH fusion (Jacobsen, *B.* 19, 1223). Long needles (from ether). Fe_2Cl_6 gives no colouration.

ψ-Cumenol $C_6H_2Me_3(OH)$. [95°]. (231° i.V.). From the corresponding cumidine [36°] by diazo-reaction (Edler, *B.* 18, 630). Formed also by fusing the corresponding sulphonic acid with potash (Jacobsen, *B.* 19, 1219). Long prisms. Gives no colour with Fe_2Cl_6. It gives a di-bromo-derivative [152°].

ψ-Cumenol $C_6H_2Me_3(OH)$. (217°). From the diazo- compound of ψ-cumidine (224°) by boiling with dilute H_2SO_4 (Engel, *B.* 18, 2230). Oil. Gives no colouration with Fe_2Cl_6.

o-**Cumenol** $C_6H_4Pr.OH$. *o-Isopropyl-phenol.* [15°]. (212° i.V.). S.G. $\frac{0}{4}$ 1·0124. From *o*-cumidine by displacing NH_2 by OH through the diazo- reaction (Fileti, *G.* 16, 113). Formed also by potash-fusion from cumene *o*-sulphonic acid (Spica, *G.* 9, 433). Its aqueous solution is coloured violet by Fe_2Cl_6. It gives a bromo- and a tri-nitro- derivative. Sodium and CO_2 gives cumenol carboxylic acid and di-oxy-di-isopropyl-diphenyl-carboxylic acid. PBr_5 gives bromo-cumene and $(C_6H_4PrO)_3PO$ (c. 378 at 280 mm.), whence alcoholic KOH forms $(C_6H_4PrO)_2(HO)PO$.

Acetyl derivative C_6H_4PrOAc. (229°). S.G. 1·03. Liquid, decomposed by prolonged boiling with water.

Methyl ether C_6H_4PrOMe. (199° cor.).

Ethyl ether C_6H_4PrOEt. (209° cor.). S.G. $\frac{0}{4}$ ·9444.

p-**Cumenol** $C_6H_4Pr(OH)$ [1:4]. [61°]. (229° cor.). From cumene *p*-sulphonic acid by potash-fusion (Paternò a. Spica, *G* 6, 535). Formed also by heating $C_6H_3(CO_2H)Pr(OH)$ [1:3:6] with conc. HCl at 180° (Jesurun, *B.* 19, 1416). Fe_2Cl_6 colours the alcoholic solution green.

Acetyl derivative C_6H_4PrOAc. (244° cor.). S.G. ^{0} 1·026.

Methyl ether $C_6H_4Pr.OMe$. (218° cor.). S.G. ^{0} ·962.

Ethyl ether $C_6H_4Pr.OEt$. (245°). S.G. ^{0} 1·026.

o-n-**Cumenol** $C_6H_4Pr(OH)$[1:2]. *o-Propyl-phenol.* (c. 225° cor.). S.G. ^{0} 1·015. From allyl iodide and phenol in presence of zinc and aluminium foil (P. F. Frankland a. T. Turner, *C. J.* 43, 358): $C_6H_5OH + C_3H_5I = HI + C_3H_5.C_6H_4OH$ and $C_3H_5.C_6H_4OH + 2HI = C_3H_7.C_6H_4OH + I_2$. Formed also by fusing the corresponding sulphonic acid with potash (Spica, *G.* 8, 418). Liquid; its aqueous solution is turned violet by Fe_2Cl_6. CO_2 acting on its sodium derivative at 140° gives *o*-oxy-propyl-benzoic acid.

Methyl ether $C_6H_4Pr.OMe$. (208° cor.). S.G. ^{0} ·9694.

m-n-**Cumenol** $C_6H_4Pr(OH)$[1:3]. [26°]. (228° i.V.). From oxy-*n*-cuminic acid and conc. HClAq at 190° (Jacobsen, *B.* 11, 1062). Crystals, v. sl. sol. water. Fe_2Cl_6 colours its alcoholic solution green.

p-n-**Cumenol** $C_6H_4Pr(OH)$[1:4]. (231° cor.). S.G. ^{0} 1·009. Formed by fusing the corresponding *n*-cumene sulphonic acid with potash (Spica, *G.* 8, 411). Formed also by diazotising amido-propyl-benzene and boiling the product with water (Louis, *B.* 16, 109). Oil. Sl. sol. cold water, v. sol. alcohol and ether. Fe_2Cl_6 gives at first a violet and then a permanent green colouration. CO_2 on the Na derivative gives *p*-oxy-*n*-cuminic acid.

Acetyl derivative $C_6H_4Pr(OAc)$. (243° cor.). S.G. ^{0} 1·029; ^{100} ·942.

Methyl ether $C_6H_4Pr(OMe)$. (215° cor.). S.G. ^{0} ·964; ^{100} ·912. Yields anisic acid on oxidation.

The same ether appears to be formed, together with anisole, by the action of boron-fluoride on anethol (Landolph, *B.* 13, 145).

Isomerides of cumenol *v.* MESITOL and HEMIMELLITHOL.

Derivatives of cumenol *v.* AMIDO-CUMENOL, BROMO-CUMENOL, NITRO-CUMENOL, &c.

Di-cumenol *v.* DI-OXY-DI-CUMYL.

CUMENOL-CARBOXYLIC ACID *v.* OXY-CUMINIC ACID.

CUMENOL SULPHONIC ACID $C_6H_3Pr(OH)(SO_3H)$. From cumenol and H_2SO_4 (Jacobsen, *B.* 11, 1062). The Ba salt forms crystalline crusts. Its solution is coloured violet by Fe_2Cl_6.

CUMENYL. A name sometimes applied to the radicle cumyl C_9H_{11}.

CUMENYL-ACRYLIC ACID *v.* CUMYL-ACRYLIC ACID.

CUMIC *v.* CUMINIC.

CUMIDIC ACID *v.* XYLENE DICARBOXYLIC ACID.

o-**CUMIDINE** $C_9H_{13}N$ *i.e.* $C_6H_4Pr(NH_2)$[1:2]. (215°). Formed by distilling amido-cuminic acid with baryta (Fileti, *G.* 13, 379). Formed also, together with the following, by nitrating cumene and reducing the product (Constam a. Goldschmidt, *B.* 21, 1157). Converted by passing over red-hot PbO into indole.

Salts.—B′HCl: large prisms.—$B'H_2C_2O_4aq$: [173°]; long prisms.

Acetyl derivative $C_9H_{11}NHAc$. [72°]. Tufts of needles.

p-**Cumidine** $C_6H_4Pr(NH_2)$[1:4]. (225°) (N.); (219°) (C. a. G.). S.G. ·953. Formed by reducing

nitro-cumene (from cuminic acid) (Nicholson, *A.* 65, 58). From aniline, isopropyl alcohol, and $ZnCl_2$ at 270° (Louis, *B.* 16, 111). May be solidified by cold. — B′HCl. — $B'_2H_2PtCl_6$. — $B'HNO_3$.—$B'_2H_2SO_4$.—$B'_2C_2N_2$: long needles (Hofmann, *A.* 66, 145). Oxalate $B'_2H_2C_2O_4$ 2aq: [159°] (Constam a. Goldschmidt, *B.* 21, 1157).

Acetyl derivative $C_9H_{11}NHAc$ [102°].

ψ-Cumidine $C_6H_2Me_3(NH_2)$[1:3:4:5]. [36°]. Formed by reduction of nitro-(pseudo)-cumene [20°] (Edler, *B.* 18, 630). Colourless crystals. Easily volatile with steam.

Salts.—B′HCl: fine felted needles.—$B'HNO_3$: small glistening plates. The oxalate and sulphate are sparingly soluble in cold water.

Acetyl derivative [194°]; long prisms; nearly insol. ether.

ψ-Cumidine $C_6H_2Me_3(NH_2)$[1:2:4:5]. [68°] (Auwers, *B.* 18, 2661); [63°] (H.). (235°). Crystalline solid.

Formation.—1. Occurs in the crude cumidine obtained by heating xylidine hydrochloride with methyl alcohol at a high temperature under pressure (Hofmann a. Martius, *B.* 4, 747; 13, 1730; Hofmann, *B.* 15, 2895; *cf.* Nölting a. Forel, *B.* 18, 2680).—2. By nitration and reduction of pseudocumene (Schaper, *Z.* 1867, 13). Large prisms. Nitrous acid converts it into $C_6H_2Me_3.N_2.C_6HMe_3(NH_2)$, whence may be obtained $C_6H_2Me_3.N_2.C_6HMe_3N_2Br_3$ [124°], $C_6H_2Me_3.N_2.C_6HMe_3.N_3$ [91°],

$C_6H_2Me_3N\genfrac{<}{>}{0pt}{}{N}{N}C_6HMe_3$ [85°] and

$C_6H_2Me_3.N_2.C_6HMe_3.N_2H$ [153°] (Zincke a. Jaencke, *B.* 21, 546).

Salts.- B′HCl: thick prisms, sol. water, sl. sol. dilute HCl. - $B'_2H_2Cl_2PtCl_4$: fine needles, decomposed by boiling water (De Coninck, *Bl.* [2] 45, 131).—$B'_2H_2SnCl_4$: laminæ.—$B'H_3PO_4$ (Lewy, *B.* 19, 2729).

Acetyl derivative $C_6H_2Me_3.NHAc$: [164°]; (360°); thick white needles; v. sol. alcohol and acetic acid, insol. water (Auwers, *B.* 18, 2661; *cf.* Nölting a. Baumann, *B.* 18, 1145).

Formyl derivative $C_6H_2Me_3.NH.COH$: [121°]; colourless prisms; v. sol. alcohol and ether, nearly insol. water.

Thioformyl derivative $C_6H_2Me_3.NH.CSH$. Formed by heating the formyl derivative with P_2S_5 (Senier, *B.* 18, 2296).

ψ-Cumidine $C_6H_2Me_3.NH_2$. (224°).

Preparation.—The solid hydrochloride obtained by adding conc. HCl to crude coml. cumidine is basified with NaOH and fractionated. The fraction c. 225°–227° is boiled with acetic acid for twelve hours, and the product crystallised from alcohol; a small quantity of acetyl-mesidine crystallises out, and the mother-liquors contain the acetyl derivative of the new cumidine, which is obtained pure by several crystallisations from water, and finally converted into the base by saponification with solid KOH.

Salts.—B′HCl: white needles; v. sol. water, nearly insol. conc. HCl. The platino-chloride is insol. water, sl. sol. alcohol. The nitrate is less soluble than the sulphate.

Acetyl derivative $C_6H_2Me_3.NHAc$: 112°]; crystalline solid (Engel, *B.* 18, 2229).

Cumidine $C_6H_2Me_3(NH_2)$[1:2:3:4]? *Hemimellithidine?* *Amido-c-tri-methyl-benzene.* 240°). From *o*-xylidine hydrochloride and MeOH at 310° (Nölting a. Forel, *B.* 18, 2680). Liquid.

Acetyl derivative $C_6H_2Me_3(NHAc)$. [above 180°].

ψ-Cumidine $C_6H_2Me_3.NH_2$[1:3:4:2]. (236° uncor.). Liquid at −15°. Obtained from nitro-ψ-cumidine (from tri-nitro-ψ-cumene) by elimination of the NH_2 group by the diazo- reaction and reduction of the nitro-ψ-cumene [30°], which is obtained with $SnCl_2$ (Mayer, *B.* 20, 971). Probably identical with the ψ-cumidine obtained by Nölting and Forel (*B.* 18, 2680) by nucleal methylation of the *o*-xylidine $C_6H_3Me_2NH_2$[2:3:1].

Acetyl derivative $C_6H_2Me_3(NHAc)$. [186°].

***n*-Cumidine** *v.* AMIDO-PHENYL-PROPANE, vol. i. p. 179.

Isomeride of cumidine *v.* PHENYL-PROPYL-AMINE.

CUMILIC ACID $C_{20}H_{24}O_3$ *i.e.* $(C_6H_4(C_3H_7))_2C(OH).CO_2H$? [120°]. Prepared by fusion of cuminil with KOH; yield 70 p.c. (Bösler, *B.* 14, 326). Fine white needles. Sol. alcohol, ether, and benzene, sl. sol. water.

CUMINAL-ACETONE *v.* METHYL PROPYL-STYRYL KETONE.

Di-cuminal-acetone *v.* DI-PROPYL-DI-STYRYL KETONE.

CUMINDIGO *v.* DI-ISOPROPYL-INDIGO.

CUMINIC ALCOHOL *v.* CUMINYL ALCOHOL.

***o-n*-CUMINIC ACID** $C_{10}H_{12}O_2$ *i.e.* $C_6H_4Pr(CO_2H)$ [1:2]. *o-n-Propyl-benzoic acid.* Mol. w. 164. [58°]. From phthalyl-propionic acid, conc. HIAq (10 pts.), and red phosphorus (1 pt.) (Gabriel a. Michael, *B.* 11, 1014). Slender leaflets.

***p-n*-Cuminic acid** $C_6H_4.Pr(CO_2H)$ [1:4]. *p-n-Propyl-benzoic acid* [140°].

Formation.—1. From *p*-bromo-*n*-propyl-benzene, sodium, and CO_2 (R. Meyer, *J. pr.* [2] 34, 102).—2. From C_6H_4PrPr by oxidation (Paternò a. Spica, *B.* 10, 1746).—3. From $C_6H_4Pr_2$ and dilute HNO_3 (H. Körner, *A.* 216, 228).

Properties.—Laminæ (from water) or needles (from dilute alcohol). Sl. sol. boiling water. Volatile with steam. $KMnO_4$ gives terephthalic acid.

Salts.—CaA'_2 3aq: slender satiny needles.—SrA'_2 2½aq.—BaA'_2 2aq.—PbA'_2 2aq.—AgA′.

Nitrile $C_6H_4Pr.CN$. [227°]. From *p*-propyl-phenyl thiocarbimide and copper powder at 220° (Francksen, *B.* 17, 1229). Liquid. Saponified by conc. HClAq at 200°.

***o*-Cuminic acid** $C_6H_4Pr.CO_2H$ [1:2]. Formed by fusing a salt of cumene-(β)-sulphonic acid with an excess of sodium formate; the yield is 10 p.c. Sublimable. Volatile with steam. V. sol. alcohol, ether, &c., insol. cold water. Oxidation with $KMnO_4$ gives *o*-phthalic acid. Its alkaline salts are excessively soluble.—A′Ag: insoluble white pp.—A'_2Ca 2aq: small soluble needles.—A'_2Ba 2aq: soluble needles.—A'_2Mg 6aq: very soluble needles.—A'_2Pb aq: very sparingly soluble white powder.—A'_2Cu 2½aq: very sparingly soluble blue-green amorphous pp.

Chloride $C_6H_4Pr.COCl$: yellowish oil, v. sol. ether and chloroform.

Amide $C_6H_4Pr.CO.NH_2$: [124° uncor.]; small needles; v. sol. alcohol and ether, v. sl. sol. water (Claus a. Schulte im Hof, *B.* 19, 3013).

p-Iso-cuminic acid $C_6H_4Pr(CO_2H)$ [1:4]. [117°] (M.). H.C.v. 1,239,000 (Berthelot a. Louguinine, *A. Ch.* [6] 13, 333).

Formation.—1. From bromo-iso-propyl-benzene, Na, and CO_2 (R. Meyer, *J. pr.* [2] 34, 100).—2. By the oxidation of cuminic aldehyde or oil of cumin (Gerhardt a. Cahours, *A. Ch.* [3] 1, 70; Beilstein a. Kupffer, *B.* 6, 1184; *A.* 170, 302; Lippmann a. Lange, *B.* 13, 1660; Meyer, *A.* 219, 244).—3. Cymene when taken internally passes into the urine as cuminic acid (Nencki a. Ziegler, *B.* 5, 749; *cf.* Hofmann, *A.* 74, 342).

Properties.—From water (3 pts.) and alcohol (1 pt.) it separates in triclinic needles: $a:b:c = \cdot6742:1:\cdot8072$; $\alpha = 86°\ 55'$, $\beta = 101°\ 12'$, $\gamma = 106°\ 55'$ (Groth; *cf.* Panebianco, *G.* 10, 81). V. sl. sol. cold water, v. sol. alcohol and ether. Converted into cumene by distillation over lime. Chromic mixture oxidises it to terephthalic acid. $KMnO_4$ forms, as an intermediate product, oxy-propyl-benzoic acid $(CH_3)_2C(OH).C_6H_4.CO_2H$ (Meyer).

Salts.—$BaA'_2$2aq: laminæ. S. ·996 at 20·5°.—$CaA'_2$5aq: needles. S. ·81 at 20·5°.—$MgA'_2$6aq: laminæ. S. ·825 at 20·5°.—AgA'.

Ethyl ether EtA'. (240°). V.D. 6·65.

Phenyl ether PhA'. [58°]. From potassium-phenol and the chloride of the acid (Williamson a. Scrugham, *Pr.* 7, 18). Also formed by distilling cuminyl-salicylic acid (Kraut, *J.* 1858, 406; *Ar. Ph.* [2] 96, 271).

Eugenyl ether $C_6H_3(C_3H_5)(OMe)A'$. Tables (Cahours, *A.* 108, 323; *A. Ch.* [3] 41, 491).

Anhydride $(C_6H_4Pr.CO)_2O$. Oil (Gerhardt, *A.* 87, 77; *A. Ch.* [3] 37, 304).

Peroxide $(C_6H_4Pr.CO)_2O_2$. Needles (from ether). Explodes when heated (Brodie, *P.* 121, 372; *Pr.* 12, 655).

Chloride $C_6H_4Pr.COCl$. (257°). S.G.^{15} 1·07. Liquid (Cahours, *A.* 70, 45; *A. Ch.* [3] 23, 347).

Amide $C_6H_4Pr.CONH_2$. [154°] (F.); [c. 157°] (G.). *Formation.*—1. By heating ammonium cuminate (Field, *A.* 65, 49).—2. From the nitrile and alcoholic KOH.—3. From the anhydride and NH_3 (Gerhardt, *A.* 87, 167).—4. By heating cuminic acid (164 g.) with potassium sulphocyanide (50 g.) for 5 hours with inverted condenser at 240°, and then for 1 hour at 300°. The nitrile is formed at the same time (Fileti, *G.* 16, 281).—5. By the action of chloroformamide $OC(NH_2)Cl$ upon cumene in presence of Al_2Cl_6 (Gattermann a. Schmidt, *A.* 244, 54; *B.* 20, 860). *Properties.*—Biaxial crystals, insol. cold water, sl. sol. ether, v. sol. alcohol and hot benzene. When boiled with water and yellow HgO it forms $(C_6H_4Pr.CONH)_2Hg$ 1½aq, which crystallises in needles [190°].

Anilide $C_6H_4Pr.CONHPh$. Long satiny needles (from alcohol). Sl. sol. alcohol (Cahours, *A. Ch.* [3] 23, 349).

Benzene sulphamide $C_6H_4Pr.CO.NH.SO_2Ph$. [161°]. From cuminyl chloride and the amide of benzene sulphonic acid (Gerhardt a. Chiozza, *A. Ch.* [3] 46, 151). Prisms. $AgNO_3$ and a little NH_3 give needles of $C_6H_4Pr.CO.NAg.SO_2Ph$, which forms a crystalline compound with NH_3 (1 mol.). The **benzoyl derivative** $C_6H_4Pr.CO.NBz.SO_2Ph$ is formed as a crystalline mass by treating $AgNBz.SO_2Ph$ with cuminyl chloride.

o-Oxy-benzamide $C_6H_4Pr.CO.NH.CO.C_6H_4.OH$. From salicylamide and cuminyl chloride. Needles.

Nitrile $C_6H_4Pr.CN$. (244° i.V.). S.G.^{14} ·765. Formed by heating the amide (Field, *Mem. Chem. Soc.* 3, 408; *A.* 65, 51), or by heating cuminic acid (2 mols.) with KCyS (1 mol.) (Letts, *B.* 5, 674; Fileti, *G.* 16, 282). Formed also by treating potassium cuminate with CyBr (Cahours, *A. Ch.* [3] 52, 201; *A.* 108, 326). Liquid, sl. sol. water, v. e. sol. alcohol and ether.

ψ-**Cuminic acid** $C_6H_2Me_3(CO_2H)$ [1:2:4:5]. *Durylic acid. Tri-methyl-benzoic acid.* [149°].

Formation.—1. By boiling durene with dilute HNO_3 (Jannasch, *Z.* 1870, 449) or with the calculated quantity of CrO_3 in HOAc (Gissmann, *A.* 216, 205).—2. By fusing potassium ψ-cumene sulphonate with sodium formate (Reuter, *B.* 11, 31).—3. From the nitrile (Nef, *A.* 237, 3).—4. By hydrolysis of its amide (*v. infra*).

Preparation.—Durene is boiled for 3 or 4 hours with dilute HNO_3 (1 vol. of HNO_3 (1·4 S.G.) to 3 vols. water). The product is filtered off, extracted with Na_2CO_3, and the solution precipitated with HCl. The crude acid is filtered off, treated with tin and HCl to remove nitro-compounds, and distilled with steam. The yield is 40–50 p.c. of the durene (Nef, *B.* 18, 2801).

Properties.—Needles (from benzene). V. sl. sol. boiling water, v. e. sol. alcohol and ether. Volatile with steam.

Salts.—$CaA'_2$2aq.—$BaA'_2$7aq: prisms.

Amide $C_6H_2Me_3.CONH_2$. [201°]. From ψ-cumene and chloroformamide $Cl.CONH_2$ in presence of Al_2Cl_6 (Gattermann, *A.* 244, 54). Needles (from dilute alcohol).

Nitrile [58°]. (250°). Formed by the action of $CuSO_4$ and KCN upon diazo-pseudo-cumene (Haller, *B.* 18, 93). Long colourless needles. V. sol. alcohol, ether, benzene, and ligroin, insol. water.

(α)-**Cuminic acid** $C_6H_2Me_3(CO_2H)$ [1:2:3:5]. [216°]. (α)-*Isodurylic acid.* Formed together with the (β) and (γ) isomerides by oxidation of isodurene with HNO_3. Distillation with lime yields hemimellithol. — A'_2Ba 4aq: long fine needles. — A'Ca 5aq (Jacobsen, *B.* 15, 1855; Bielefeldt, *A.* 198, 384).

(β)-**Cuminic acid** $C_6H_2Me_3(CO_2H)$ [1:3:5:2]. (β)-*Isodurylic acid. Mesitylene carboxylic acid.* [151°]. Formed together with the (α) and (γ) isomerides by oxidation of iso-durene with HNO_3 (Jacobsen, *B.* 15, 1855). Distils without decomposition. Thick glistening prisms. On distillation with lime it gives mesitylene. $CaA'_2$2aq: microscopic needles.

(γ)-**Cuminic acid** $C_6H_2Me_3(CO_2H)$ [1:2:4:6]. *ψ-Cumene carboxylic acid.* (γ)-*Isodurylic acid.* [85°]. Formed together with the (α)- and (β)-isomerides by oxidation of isodurene with HNO_3 (Jacobsen, *B.* 15, 1855). Distils without decomposition. Volatile with steam. Needles. Sol. alcohol, ether, and hot water, nearly insol. cold water. On distillation with lime it gives pseudo-cumene.

Salts.—$A'K^x$: extremely soluble amorphous solid. — A'_2Ba^x: uncrystallisable. — A'_2Ca 2aq: microscopic needles.

c-**Cuminic acid** $C_6H_2Me_3(CO_2H)$[1:2:3:4]. *Tri-methyl-benzoic acid.* [168°]. Formed by oxidation of the consecutive tetra-methyl-benzene (prohnitene) by boiling for 12 hours with dilute HNO_3. Long glistening prisms. V. e. sol. hot alcohol. Volatile with steam. By distillation with lime it yields the consecutive tri-methyl benzene (hemimellithene) (Jacobsen, *B.* 19, 1214).

References. — AMIDO-CUMINIC ACID, BROMO-CUMINIC ACID, NITRO-CUMINIC ACID, OXY-CUMINIC ACID.

CUMINIC ALDEHYDE $C_{10}H_{12}O$ *i.e.* $C_6H_4(C_3H_7).CHO$ [1:4]. *Cuminol. Isopropyl-benzoic aldehyde.* Mol. w. 148. (237·5° cor.) (Schiff); (222° cor.) (Lippmann a. Strecker, *Sitz. W.* [2] 78, 570). S.G. $\frac{0}{}$ ·9832; $\frac{13\cdot4}{}$ ·9727. V.D. 5·24 (calc. 5·13). Occurs, together with cymene, in oil of cumin (from *Cuminum Cyminum*), and in the volatile oil from the seeds of the water-hemlock (*Cicuta virosa*). It is separated from these oils by $KHSO_3$ (Gerhardt a. Cahours, *A. Ch.* [3] 1, 60; Bertagnini, *A.* 85, 275; Kraut, *A.* 98, 366; Trapp, *A.* 108, 386). Formed by boiling $C_3H_7.C_6H_4.CH_2Cl$ with lead nitrate and water (Errera, *G.* 14, 278). Formed also by treating cymene (1 mol.) with CrO_2Cl_2 (3 mols.) in CS_2, without cooling, and decomposing the product with water (Etard, *C. R.* 90, 534). The cuminic aldehyde (220°) so formed is perhaps identical with ordinary cuminic aldehyde. On oxidation it gives a cuminic acid [129°], whence potash-fusion gives *p*-toluic acid.

Properties.—Oil, smelling like oil of cumin. Oxidises in the air, becoming resinous.

Reactions.—1. Cold fuming HNO_3 gives *p*-iso-cuminic acid. Hot HNO_3 forms nitro-iso-cuminic acid.—2. *Chromic acid mixture* gives *p*-iso-cuminic and finally terephthalic acid.—3. Cl and Br act by substitution.—4. NH_3 forms hydrocumin-amide a thick liquid (Gerhardt a. Cahours; Borodin, *B.* 6, 1253). According to Uebel (*A.* 245, 303) it is a stellate mass [65°] which may be reduced by sodium amalgam to cuminyl-amine and di-cuminyl-amine, and is converted by dilute acids into NH_3 and cuminic aldehyde. Sieveking (*A.* 106, 357) could not obtain it. Aqueous NH_3 at 130° forms an isomeric base $C_{30}H_{40}N_2$ [205°] which forms a sparingly soluble sulphate [192°].—5. *Ammonium sulphide* forms $(C_{10}H_{12}S)_x$.—6. Boiling *aqueous* and *alcoholic potash* form cuminyl alcohol and *p*-iso-cuminic acid.—7. *Potash-fusion* gives *p*-iso-cuminic acid and cymene.—8. Heating with potassium forms $C_{10}H_{11}OK$(?) (Chiozza, *A.* 87, 302; *cf.* Church, *P. M.* [4] 25, 522).—9. In ethereal solution it is partly converted by treatment with *sodium amalgam* into the sodium derivative of hydrocuminoïn $C_6H_4Pr.CH(OH).CH(OH).C_6H_4Pr$ [135°] (M. Wallach, *A.* 226, 78; *cf.* Claus, *A.* 137, 104).—10. *Acetamide* at 175° gives $C_6H_4(C_3H_7)CH(NHAc)_2$ [212°] (Raab, *B.* 8, 1150).—11. *Benzamide* gives in the same way $C_6H_4(C_3H_7)CH(NHBz)_2$ [224°] which crystallises from alcohol in needles, insol. water (R.).—12. *Ethylene-diamine* at 120° gives $(C_3H_7.C_6H_4.CH{:}N)_2C_2H_4$ [64°] (Mason, *B.* 20, 267). — 13. Hydrogen cyanide and HCl give $C_6H_4(C_3H_7).CH(OH).CO_2H$.—14. Distillation over $ZnCl_2$ gives cymene (Louguinine, *Z.* 1867, 351). 15. With butyric aldehyde and butyric anhydride it gives $C_3H_7.C_6H_4.CH{:}CEt.CO_2H$ (Perkin).

Combination.—$C_{10}H_{12}(OH)(SO_3Na)$ aq: needles, sol. water, insol. cold alcohol, ether, and aqueous $NaHSO_3$.

Di-methyl-amido-anilide $C_6H_4(C_3H_7).CH{:}N.C_6H_4(NMe_2)$: [99°]; small glistening crystals (from alcohol) (Nuth, *B.* 18, 573).

Oxim $C_{10}H_{12}.NOH$. [52°]. Formed by the action of hydroxylamine on cuminic aldehyde (Westenberger, *B.* 16, 2994). Sl. sol. water.

Derivatives of cuminic orthaldehyde.

Diacetyl derivative $C_6H_4(C_3H_7)CH(OAc)_2$. Obtained by the action of silver acetate on $C_6H_4(C_3H_7)CHCl_2$ (from cuminol and PCl_5). Crystals (Sieveking, *A.* 106, 258).

Di-benzoyl derivative $C_6H_4(C_3H_7).CH(OBz)_2$. [88°]. Needles (Tüttscheff, *A.* 109, 368).

Di-thymyl derivative $C_6H_4(C_3H_7).CH(OC_{10}H_{13})_2$. [157°]. From $C_6H_4(C_3H_7).CHCl_2$, thymol, and KOH (Engelhardt a. Latschinoff, *Z.* 1869, 43). Tables.

Cuminoïn $C_{20}H_{24}O_2$ *i.e.* $C_6H_4(C_3H_7).C(OH)H.CO.C_6H_4(C_3H_7)$. [101°]. Prepared by boiling cuminic aldehyde with alcoholic KCN; the yield is about 45 p.c. (Bösler, *B.* 14, 323). Slender white needles; sol. alcohol, ether, and benzene, sl. sol. water and ligroïn. It reduces Fehling's solution in the cold. Alcoholic KOH gives a violet colouration.

Acetyl derivative $C_{20}H_{23}O(OAc)$: [75°]; tables or prisms (Widmann, *B.* 14, 609).

Hydrocuminoïn $C_3H_7.C_6H_4.CH(OH).CH(OH).C_6H_4.C_3H_7$. [135°].

Formation.—1. From cuminoïn and sodium amalgam.—2. From cuminic aldehyde by treating its ethereal solution with sodium amalgam or with alcoholic HCl and zinc (Claus, *A.* 137, 104; Raab, *B.* 10, 54).—3. Its di-acetyl derivative is formed by heating cuminic aldehyde with NaOAc and Ac_2O at 160° (Widmann, *B.* 19, 256).

Properties.—Small needles (from dilute alcohol). Insol. water. Oxidised by conc. HNO_3 to cuminoïn. Pentachloride of phosphorus gives $C_3H_7.C_6H_4.CHCl.CHCl.C_6H_4.C_3H_7$ [185°].

Di-acetyl derivative $C_{20}H_{24}Ac_2O_2$. [144°].

Deoxy-cuminoïn $C_3H_7.C_6H_4.CH_2.CO.C_6H_4.C_3H_7$. [58°]. From cuminic aldehyde by treatment with zinc and alcoholic HCl (B.). Slender laminæ (from dilute alcohol); v. sl. sol. water.

Cuminil $C_{20}H_{22}O_2$ *i.e.* $C_6H_4(C_3H_7).CO.CO.C_6H_4(C_3H_7)$. [84°]. Yellow prisms. Sol. alcohol, ether, and benzene, v. sl. sol. water. Distils undecomposed. Prepared by oxidation of cuminoïn with chlorine. On fusion with caustic potash it gives rise to cumilic acid $(C_3H_7.C_6H_4)_2C(OH).CO_2H$ [120°] (Bösler, *B.* 14, 325).

Isocuminic aldehyde $C_{10}H_{12}O$. [80°]. (220°). Formed together with the liquid aldehyde by the action of water upon the compound $C_{10}H_{14}2CrO_2Cl_2$, obtained from cymene derived from turpentine (Etard, *A. Ch.* [5] 22, 259). Solid resembling camphor. Oxidised by the air to a cuminic acid [51°].

CUMINOL *v.* CUMINIC ALDEHYDE.

CUMINURIC ACID $C_{12}H_{15}NO_3$ *i.e.* [4:1]$C_6H_4(C_3H_7).CO.NH.CH_2.CO_2H$. [168°]. Occurs in the urine of animals who have been given doses of cymene (Jacobsen, *B.* 12, 1512). Prepared by the action of cuminyl chloride on glycocol-silver (Cahours, *A. Ch.* [3] 53, 356). Glistening scales or large plates. Insol. cold water, sol. hot water and alcohol. On heating with HCl to 120° it decomposes into glycocol and cuminic acid [117°].

Salts.—BaA'_2 aq: leaflets or flat needles, S. ·45 at 6°.—CaA'_2 3aq: fine needles, sl. sol. cold water.—KA' and NaA': very soluble fine needles.

DI-CUMINYL $C_{20}H_{26}$ *i.e.* $C_3H_7.C_6H_4.CH_2.CH_2.C_6H_4.C_3H_7$. (above 360°). From cuminyl chloride and sodium (Cannizzaro a. Rossi, *A.* 121, 251). Plates.

CUMINYL ALCOHOL $C_{10}H_{14}O$ *i.e.* C_6H_4Ᵽr.CH_2OH [4:1]. Mol. w. 150. (247° cor.). S.G. ^{15} ·978. Formed, together with cuminic acid, by boiling cuminic aldehyde with alcoholic potash (Kraut, *A.* 92, 66; 192, 224; Fileti, *G.* 14, 498). Liquid, miscible with alcohol and ether. Boiling with zinc-dust converts it into *n*-cymene, the Ᵽr changing to Pr. Boiling alcoholic KOH forms cuminic acid and cymene. Boiling with small quantities of dehydrating agents converts it into di-cuminyl oxide.

CUMINYL-AMIDO-PHENOL $HO.C_6H_4.NH.CH_2.C_6H_4$Pr. *Oxy-phenyl-cuminyl-amine.* [108°]. Formed by reducing with sodium amalgam the product obtained by the action of cuminol on amidophenol (Uebel, *A.* 245, 297). Greyish white plates. V. e. sol. alcohol, ether.

Salts.—$C_{16}H_{17}NH(ONa)$. V. sol. water, giving a red solution.—B'HCl. White plates. V. sol. alcohol, hot water, m. sol. cold water.

Nitrosamine $C_{16}H_{17}OHN.NO$. Yellowish brown crystalline substance. V. sol. alcohol, ether.

CUMINYL-AMINE $C_{10}H_{15}N$ *i.e.* $C_6H_4(C_3H_7).CH_2.NH_2$[1:4]. *Exo-amido cumene. Isopropyl-benzyl-amine.* (226° at 724 mm.). Prepared by reduction of the oxim of cuminic aldehyde, $C_6H_4(C_3H_7).CH:NOH$ (5 pts.), with sodium amalgam (150 pts.) and acetic acid (12 pts.) in alcoholic solution at 40°-50°; the yield is good (Goldschmidt a. Gessner, *B.* 20, 2413). Formed also, together with di- and tri-cuminyl-amine, by heating cuminyl chloride with alcoholic NH_3 at 100° (Rossi, *C. R.* 51, 570; *A. Suppl.* 1, 141). Also from thio-cuminic amide $C_3H_7.C_6H_4.CS.NH_2$, zinc and alcoholic HCl (Czumpelik, *B.* 2, 185). Colourless liquid, of basic smell. Nearly insol. water. Absorbs CO_2 from the air, and solidifies to a crystalline carbamate.

Salts.—B'HCl: glistening colourless plates, v. sol. water and alcohol.—$B'_2H_2Cl_2PtCl_4$: nearly insoluble yellow pp.

Acetyl derivative $C_{10}H_{13}(NHAc)$: [65°]; pearly plates; v. sol. alcohol, ether, and benzene, sl. sol. hot water and hot ligroïn.

Di-cuminyl-amine $(C_3H_7.C_6H_4)_2NH$. [168°]. (c. 290° at 100 mm.). Formed as above (R.). Formed also by the action of sodium amalgam on the product of the action of dry NH_3 on cuminic aldehyde (Uebel, *A.* 245, 309). Crystals, insol. water, v. sol. alcohol and ether. Forms a crystalline nitrosamine.

Salts.—B'HCl: plates (from alcohol); v. sl. sol. cold, m. sol. hot, water, v. e. sol. alcohol.—$B'_2H_2PtCl_6$: yellow needles.

Tri-cuminyl-amine $(C_3H_7.C_6H_4)_3N$. [82°]. Formed as above (R.). Its hydrochloride forms needles, insol. water.

CUMINYL-CARBAMATE $NH_2.CO_2.CH_2.C_6H_4.C_3H_7$. [89°]. Formed, together with ω-chloro-cymene, by passing cyanogen chloride into cuminyl alcohol (Spica, *G.* 5, 394). Prisms, not volatile with steam. Sl. sol. cold, v. sol. hot, water.

CUMINYL CHLORIDE *v.* ω-CHLORO-CYMENE.

CUMINYL-ETHYL OXIDE C_6H_4Ᵽr.O.Et. (227°). From ω-chloro-cymene and alcoholic KOH (Errera, *G.* 14, 282).

CUMINYLIDENE-ACETONE $CH_3.CO.CH:CH.C_6H_4$Ᵽr. (181° at 23 mm.). From acetone (20 pts.), cuminic aldehyde (20 pts.), water (300 pts.), alcohol (170 pts.), and NaOH (2 pts.) in the cold (Claisen a. Ponder, *A.* 223, 147). Thick yellowish oil.

Di-cuminylidene-acetone $(C_6H_4$Ᵽr$.CH:CH)_2CO$. [107°]. From cuminic aldehyde (20 pts.), acetone (4 pts.), water (300 pts.), alcohol (250 pts.), and NaOH (2 pts.), in the cold (C. a. P.). Long light-yellow prisms (from alcohol).

CUMINYLIDENE-AMIDO-PHENOL $HO.C_6H_4N:CH.C_6H_4$Pr. [183°]. Formed by the action of amidophenol on an alcoholic solution of cuminol (Uebel, *A.* 245, 296). Green prismatic needles (from alcohol). Is converted by sodium amalgam into cuminyl amido-phenol.

CUMINYLIDENE CHLORIDE *v.* ωω-DI-CHLORO-CYMENE.

DI-CUMINYLIDENE-ETHYLENE-DIAMINE $C_{22}H_{28}N_2$ *i.e.* $C_2H_4(N:CH.C_6H_4$Ᵽr$)_2$. *Di-isopropyl-benzylidene-ethylene diamine.* [64°]. Formed by heating ethylene diamine (1 mol.), with cuminic aldehyde (2 mols.) to 120°. Long white needles. Easily soluble in alcohol, benzene, chloroform, and petroleum-ether. Decomposed into its constituents by acids or by heating with water (Mason, *B.* 20, 270).

CUMINYLIDENE-DI-METHYL-*p*-PHENYLENE DIAMINE Ᵽr.$C_6H_4CH:NC_6H_4NMe_2$. [100°]. Formed by the action of Ᵽr.$C_6H_4.CHO$ on di-methylaniline (Uebel, *A.* 245, 299). Lemon-yellow needles. V. sol. alcohol and ether, insol. water. Is decomposed by acids or alkalis into its components.

CUMINYL-DI-METHYL-*p*-PHENYLENE DIAMINE Ᵽr.$C_6H_4.CH_2.NH.C_6H_4.NMe_2$. [39°]. Formed by reducing cuminylidene-di-methyl-*p*-phenylene-diamine with sodium amalgam in an alcoholic solution (Uebel, *A.* 245, 300). Colourless prismatic plates. V. e. sol. alcohol and ether. Gives a nitroso- derivative [87°], crystallising in yellow needles. The **hydrochloride** is v. sol. water, v. e. sol. alcohol, and sl. sol. ether.

DI-CUMINYL OXIDE $C_{20}H_{26}O$ *i.e.* $(C_6H_4$Ᵽr$.CH_2)_2O$. (350°).

Formation.—1. From C_6H_4Ᵽr.CH_2ONa and C_6H_4Pr.CH_2Cl (Fileti, *G.* 14, 496).—2. By distilling cuminyl alcohol with dilute H_2SO_4.—3. One of the products of the action of alcoholic potash on cuminic aldehyde.

Properties.—Oil. Boils at 350° with partial decomposition into cuminic aldehyde and cymene.

CUMINYL-PHENOL $C_{16}H_{18}O$ *i.e.* $C_3H_7.C_6H_4.CH_2.C_6H_4OH$. (300°) at 60 mm. Formed by treating a mixture of phenol and cuminyl alcohol with HOAc and H_2SO_4 (Paternò a. Fileti, *G.* 5, 383).

CUMINYL THIOCARBIMIDE C_6H_4Ᵽr.CH_2NCS. (245°-270°). From di-cuminyl-thio-urea and P_2O_5 (Raab, *B.* 10, 52).

CUMINYL-THIO-UREA $C_6H_4(C_3H_7).CH_2.NH.CS.NH_2$ [1:4]. *Propyl-benzyl-thio-urea.* [c. 110°]. Formed by mixing solutions of ammonium sulphocyanide and cumyl-amine hydrochloride, and evaporating to dryness. Colourless plates (Goldschmidt a. Gessner, *B.* 20, 2416).

Di-cuminyl-thio-urea $\{C_6H_4(C_3H_7).CH_2.NH\}_2CS$[1:4]. *Di-p-propyl-di-benzyl-thio-urea.* [128°]. Formed by the action of alcoholic sulphide of carbon upon cumylamine $C_6H_4(C_3H_7).CH_2.NH_2$. Glistening needles (Raab, *B.* 10, 53; Goldschmidt a. Gessner, *B.* 20, 2415).

CUMINYL-UREA $C_{11}H_{16}ON_2$ *i.e.* $C_6H_4(C_3H_7).CH_2.NH.CO.NH_2$ [1:4]. *Propyl-benzyl-urea.* [135°]. Formed by warming a solution of cumylamine hydrochloride with potassium cyanate. Slender white needles (from hot water) (Raab, *B.* 8, 1151; Goldschmidt a. Gessner, *B.* 20, 2414).

Di-cuminyl-urea $(C_3H_7.C_6H_4.CH_2.NH)_2CO$. [122°]. From cuminyl cyanate and cuminyl amine (Raab, *B.* 10, 52). Small needles.

CUMONITRILE *v. Nitrile of* Cuminic acid.

CUMOPHENOL *v.* Cumenol.

CUMOQUINOLINE *v.* (*iso*)-Propyl-quinoline.

ψ-CUMOQUINONE $C_6HMe_3O_2$ [2:3:5:4:1]. [11°]. Formed by oxidising isoduridine $C_6HMe_4(NH_2)$ [2:3:5:4:1]. Needles (from water). Liquid above 11°. Reduced by SO_2 to hydro-cumoquinone $C_6HMe_3(OH)_2$ [169°] (Nolting a. Baumann, *B.* 18, 1152).

ψ-CUMOQUINONE CARBOXYLIC ACID $C_6Me_3O_2.CO_2H$ (1:3:4:2:5:6). [128°]. Formed by oxidising an aqueous solution of the chloride of di-amido-tri-methyl-benzoic acid with Fe_2Cl_6 (Nef, *A.* 237, 11). Golden yellow needles. V. sol. alcohol, ether, chloroform, m. sol. petroleum ether.

Reactions.—Liberates CO_2 from carbonates; sol. alkalis and ammonia with yellow colour. Hydroxylamine yields an unstable quinone oxim. HNO_3 (1.4) yields nitro-tri-methyl-quinone. Reduced by zinc-dust and aqueous NaOH to di-oxy-tri-methyl-benzoic acid. The Ag, Pb, Ba, and Cu salts are all yellow.

Ethyl ether $C_6O_2Me_3CO_2Et$. [51°]. Yellow needles. V. sol. alcohol and ether, m. sol. ligroin.

CUMOSTYRIL *v.* (*Py.* 3)-Oxy-(*B.* 3)-isopropyl-quinoline.

CUMYL. This name is sometimes given to the radicles cuminyl $C_9H_{11}.CH_2$ and cuminoyl $C_9H_{11}.CO$, but it is used in this dictionary to denote the radicle C_9H_{11}; cumyl being propyl-phenyl, while ψ-cumyl is *u*-tri-methyl-phenyl.

CUMYL-ACRYLIC ACID $C_{12}H_{14}O_2$ *i.e.* $C_6H_4(C_3H_7)CH:CH.CO_2H$ [4:1]. *Isopropyl-cinnamic acid.* [158°]. From cuminic aldehyde, NaOAc, and Ac_2O (Perkin, *C. J.* 31, 388; Widmann, *B.* 19, 255). Needles (from alcohol). V. sol. alcohol and HOAc, sl. sol. boiling water. Split up by heat into CO_2 and isopropyl-styrene. Aqueous CrO_3 gives cuminic aldehyde. Sodium amalgam gives β-*n*-cumyl-propionic acid.

Salts.—*NH_4A': asbestos-like crystals, m. sol. water.—CaA'_2: needles, sl. sol. water; absorbs oxygen at 100°.—SrA'_2 2aq.—AgA': bulky pp.

Chloride $C_6H_4Pr.CH:CH.COCl$. [c. 25°].

Amide $C_6H_4Pr.CH:CH.CONH_2$. [186°].

Derivatives *v.* Amido-, Nitro-, and Oxy-cumyl-acrylic acid.

Di-bromide $C_6H_4(C_3H_7).CHBr.CHBr.CO_2H$. [190°]. Small white balls. Sparingly sol. in hot benzene (Widmann, *B.* 19, 258).

ψ-CUMYL-AMIDO-CROTONIC ACID $Me_3C_6H_2NH.C(Me):CHCO_2Et$. Formed by the action of acetoacetic ether on $C_6H_2Me_3(NH_2)$ [1:2:4:5] (Conrad a. Limpach, *B.* 21, 528). Viscous mass. Yields on distillation di-cumyl-urea and a quinoline derivative.

Methyl ether MeA′. [60°]. Formed by the action of methyl acetoacetate on ψ-cumidine (Conrad a. Limpach, *B.* 21, 528). White crystals (from alcohol). Yields a quinoline derivative on distillation.

CUMYL-ANGELIC ACID $C_{14}H_{18}O_2$ *i.e.* $C_6H_4(C_3H_7)CH:CEt.CO_2H$. [123°]. From cuminic aldehyde, butyric anhydride, and sodium butyrate (Perkin, *C. J.* 31, 403). Needles (from alcohol). Forms a crystalline dibromide.

CUMYL BROMIDE *v.* Bromo-cumene.

CUMYL CHLORIDE *v.* Chloro-cumene.

CUMYL-CROTONIC ACID $C_{13}H_{16}O_2$ *i.e.* $C_6H_4(C_3H_7).CH:CMe.CO_2H$. [91°]. From cuminic aldehyde, propionic anhydride, and NaOAc (Perkin, *C. J.* 31, 403; 35, 137). Nodules (from alcohol) or prisms (from light petroleum).—AgA': bulky pp.

Di-bromide $C_6H_4(C_3H_7)CHBr.CMeBr.CO_2H$. [140°–150°]. Prisms. Converted by KOH into allyl-isopropyl-benzene.

ψ-CUMYLENE-*m*-DIAMINE $C_6HMe_3(NH_2)_2$ [1:3:4:2:6]. [84°]. Formed by reduction of nitro-ψ-cumidine (from tri-nitro-ψ-cumene) or of the corresponding nitro-ψ-cumidine sulphonic acid. Long thick needles. Fe_2Cl_6 gives a dark red colouration. Gives the Bismarck-brown and chrysoidine reactions. The hydrochloride forms white plates (Mayer, *B.* 20, 970).

Isomerides *v.* Di-amido-cumene.

CUMYLENE BROMIDE *v.* Di-bromo-cumene.

DI-ψ-CUMYL-ETHYLENE-DI-KETONE [5:4:2:1]. $C_6H_2Me_3.CO.CH_2.CH_2.CO.C_6H_2Me_3$ [1:2:4:5]. [120°]. Formed by the action of succinyl-chloride upon ψ-cumene (over 2 mols.) in presence of Al_2Cl_6. On oxidation it gives tri-methyl-benzoic acid [150°] (Claus, *B.* 20, 1378).

ψ-CUMYL-ETHYL-KETONE-ω-CARBOXYLIC ACID $C_6H_2Me_3.CO.CH_2.CH_2.CO_2H$ [5:4:2:1]. [105° uncor.]. Its chloride is formed by the action of succinyl chloride (1 mol.) upon ψ-cumene (1 mol.) in presence of Al_2Cl_6. Small colourless crystals (Claus, *B.* 20, 1378).

ψ-CUMYL-HYDRAZINE $C_6H_2(CH_3)_3.NH.NH_2$ [1:3:4:6]. [120°]. Formed by reduction of the sulphite of diazo-pseudo-cumene with zinc-dust and acetic acid, and heating the sulphite which is formed with dilute HCl (Haller, *B.* 18, 91). Colourless needles, v. sol. alcohol and ether, nearly insol. water. By boiling with aqueous $CuSO_4$ it is converted into pseudo-cumene.

CUMYLIDENE-ETHYLENE-ANILINE *v.* Di-phenyl-ψ-cumyl-metapyrazol-tetrahydride.

CUMYLIZIN-ACETO-ACETIC ETHER *v.* Aceto-acetic-ether-cumyl-hydrazide.

DI-CUMYL DI-KETONE is *Cuminil* *v.* Cuminic aldehyde.

CUMYL PROPYL-BENZYL KETONE is *Deoxy-cuminoïn* *v.* Cuminic aldehyde.

ψ-CUMYL MERCAPTAN $C_9H_{12}S$ *i.e.* $C_6H_2Me_3(SH)$ [1:2:4:5]. [87°]. (235°). Formed by reduction of ψ-cumene sulphonic chloride (Beilstein a. Kögler, *A.* 137, 322). Laminæ (from alcohol).—$(C_6H_2Me_3S)_2Hg$: needles (from alcohol) (Radloff, *B.* 11, 32).

CUMYL METHYL KETONE $C_6H_4Pr.CO.CH_3$. (253° i.V.). S.G. $^{\underline{15}}$ ·976. From cumene, AcCl, and Al_2Cl_6 (Widmann, *B.* 21, 2225).

Oxim $C_6H_4Pr.C(NOH).CH_3$. [71°]. Trimetric tables (from ligroïn).

p-**CUMYL-PROPIONIC ACID** $C_{12}H_{16}O_2$ *i.e.* $C_6H_4(C_3H_7).CH_2.CH_2.CO_2H$. [76°]. From cumylacrylic acid and sodium-amalgam or HI (Perkin, *C. J.* 31, 388; Widmann, *B.* 19, 2773). Laminæ (from ligroïn).—AgA′.

ψ-CUMYL DISULPHIDE $(C_6H_2Me_3)_2S_2$. [115°]. From ψ-cumyl mercaptan and ψ-cumene sulphonic acid in alcohol (Radloff, *B.* 11, 32).

DI-ψ-CUMYL-THIO-UREA $SC(NH.C_6H_2Me_3)_2$. [146°]. Formed by heating ψ-cumidine (224°) with CS_2. Prismatic crystals. Sol. hot alcohol, sl. sol. ether, insol. water (Engel, *B.* 18, 2233).

ψ-CUMYL-UREA $C_6H_2Me_3.NH.CO.NH_2$. Formed by mixing aqueous solution of (σ)-cumidine hydrochloride and potassium cyanate. White needles. Sol. hot alcohol, sl. sol. ether, insol. water. Decomposes at c. 227° without melting, evolving NH_3 and giving di-(σ)-cumyl-urea (Engel, *B.* 18, 2232).

o-**Cumyl-urea** [2:1] $C_6H_4Pr.NH.CO.NH_2$. [134°]. Small needles (Constam a. Goldschmidt, *B.* 21, 1157).

p-**Cumyl-urea** [4:1] $C_6H_4Pr.NH.CO.NH_2$. [152°]. Slender needles (C. a. G.).

Di-ψ-cumyl-urea $OC(NH.C_6H_2Me_3)_2$. [above 290°]. White silky needles. Sublimable. Sl. sol. alcohol. Formed by heating the monocumyl-urea, NH_3 being evolved (Engel, *B.* 18, 2233).

Di-ψ-cumyl-urea $Me_3C_6H_2NH.CO.NH.C_6H_2Me_3$ [above 300°]. Is a product of the distillation of the ethyl or methyl ether of ψ-cumyl-amido-crotonic acid $C_6H_2Me_3.NH.CMe{:}CH.CO_2H$ (Conrad a. Limpach, *B.* 21, 528). White needles, insol. ordinary solvents.

CUPREÏNE *v.* Cinchona bases.

CUPRONINE *v.* Narcotine.

CURARINE $C_{18}H_{35}N$ (?) Occurs as sulphate in curara or urari, a resinous arrow-poison used by the South American Indians, and said to be obtained by boiling a climbing plant of the genus *Strychnos* with water. Deliquescent prisms; v. sol. water and alcohol, m. sol. chloroform, insol. ether. It is coloured red by conc. H_2SO_4. HNO_3 gives a purple-red colour. K_2SO_4 and H_2SO_4 give a violet colour like that from strychnine.—$B'_2H_2PtCl_6$: yellowish white pp. —**Picrate** $B'C_6H_2(NO_2)_3OH$: yellow pp. (Roulin a. Boussingault, *A. Ch.* [2] 39, 24; A. von Humboldt, *A. Ch.* [2] 39, 30; Pelletier a. Pétroz, *A. Ch.* [2] 40, 213; Pelouze a. Cl. Bernard, *C. R.* 31, 553; 40, 1327; Reynoso, *C. R.* 39, 697; Pelikan, *C. R.* 44, 507; Milleroux, *C. R.* 47, 973; Preyer, *Bl.* [2] 4, 238; Dragendorff, *Z.* [2] 3, 28; Bert, *C. C.* 1865, 958; Schnetzler, *N. Arch. ph. nat.* 24, 318; Flückiger, *N. Repert. Pharm.* 22, 65; Koch, *C. C.* 1871, 219; Salomon, *Fr.* 10, 454; Bœhm, *C. C.* 1887, 520; Sachs, *A.* 191, 254; Villiers, *J. Ph.* [5] 11, 653).

CURCUMIN $C_{14}H_{14}O_4$. [178°]. The colouring matter of turmeric root, from which it may be obtained by extracting with ether after removing an oil by ligroïn (Vogel, *Schw. J.* 18, 212; Pelletier a. Vogel, *J. Ph.* 1815, 259; Vogel, jun., *A.* 44, 297; Daube, *B.* 3, 609; Schützenberger, *Bl.* [2] 5, 194; Jackson a. Menke, *Am.* 4, 79; 6, 77; *P. Am. A.* 17, 110). Stout needles (from alcohol); nearly insol. water, benzene, CS_2, and ligroïn; sol. HOAc, alcohol, and ether. Its ethereal solution exhibits green fluorescence. Its alkaline solutions are brown, but it is reppd. unaltered by acids. Salts of Ba, Ca, and Pb give brown pps. in the alkaline solution. Paper stained with curcumin and moistened with boracic acid becomes, according to Daube, orange after drying; turmeric paper becomes crimson under these conditions; in either case the colour is turned bluish-black by alkalis. Treatment with boracic acid and conc. H_2SO_4 gives '**rosocyanin**,' of which the solutions are magenta and the metallic salts blue. Chromic acid mixture oxidises curcumin to terephthalic acid (Gajevsky, *B.* 6, 196). According to Kachler (*B.* 3, 713) distillation over zinc-dust yields anthracene.

Metallic derivatives $C_{14}H_{13}KO_4$: very dark crimson amorphous body, sol. water and alcohol.—$C_{14}H_{12}K_2O_4$: orange-red needles, sol. water, insol. ether. Long boiling with EtI forms a di-ethyl derivative.

Acetyl derivative $C_{14}H_{13}AcO_4$. Brown mass, sol. alcohol and HOAc, sl. sol. ether and benzene, insol. CS_2.

Diacetyl derivative $C_{14}H_{12}Ac_2O_4$. [154°]. Formed by heating curcumin with Ac_2O and NaOAc. Yellow trimetric plates. Conc. H_2SO_4 forms a blood-red solution with green reflex.

p-Bromo-benzyl derivative $C_{14}H_{13}(C_6H_3BrMe)O_4$. [78°]. From potassium curcumin and *p*-bromo-benzyl bromide in alcohol. Yellow crystals, sol. alcohol and HOAc. Oxidised by $KMnO_4$ to vanillin.

CUSCAMINE *v.* Cinchona bases.

CUSCONIDINE *v.* Cinchona bases.

CUSCONINE *v.* Cinchona bases and Aricine.

CUSPARINE $C_{19}H_{17}NO_3$. [92°]. An alkaloid present in the Angustura bark (from *Cusparia febrifuga*). An ethereal solution of this bark yields with oxalic or sulphuric acids pps. of the corresponding salts as yellow crystalline substances, which yield on decomposition the alkaloid. Long colourless needles, sol. petroleum. Decomposed by potash into an aromatic acid, and another alkaloid [250] (Körner a. Böhringer, *G.* 13, 363; *cf.* Saladin, *J. chim. med.* 1833, 9, 388; Herzog, *Ar. Ph.* [2] 93, 146).

Salts.—The **sulphate**, **hydrochloride**, and **oxalate** are sparingly soluble, the **tartrate** is readily soluble in water. The **platinochloride** is an orange yellow pp.

CYAMELIDE *v.* Cyanic acid.

CYAMELURIC ACID *v.* Cyanic acid.

CYAMIDO- = Cyanamido-.

CYANAMIDE *v.* Cyanic acid.

Di-cyan-diamide *v.* Cyanic acid.

CYANAMIDE-CARBOXYLIC ACID Cy.NH.CO_2H. Only some salts of this dibasic acid are known (G. Meyer, *J. pr.* 126, 419). The acid, when liberated, splits up into CO_2 and cyanamide.

Salts.—$CyNNa.CO_2Na$. Formed by passing carbonic acid into a boiling alcoholic solution of sodium cyanamide: $2CyNNaH + CO_2 = CyNH_2 + CyNNa.CO_2Na$. Amorphous powder, insoluble in alcohol, soluble in water. May be obtained in groups of microscopic needles by dropping its aqueous solution into alcohol. Converted by fusion into the isomeric sodic cyanate.—$CyNK.CO_2K$. Got by passing CO_2 into boiling alcoholic potassic cyanamide. Resembles the foregoing sodium salt.—$\{CyN(CO_2)\}Ca$, 5aq. In a similar way from calcium cyanamide, by passing CO_2 into its alcoholic solution. Thin white needles, slightly soluble in water. Its aqueous solution is decomposed by heat into $CaCO_3$ and cyanamide.—$\{CyN(CO_2)\}Sr$, 2½aq. Gritty crystalline powder, resembling the calcium salt.—$\{CyN(CO_2)\}Ba$, 1½aq. Resembles the strontium salt.

Reactions.—A solution of the potassium salt gives:—1. With silver nitrate a pp. of silver cyanamide and evolution of CO_2.—2. With basic lead acetate a white pp. of lead carbonate, cyanamide being in solution.

Ethyl ether $CN.NH.CO_2Et$. From cyanamide di-carboxylic ether and alcoholic KOH (Bässler, *J. pr.* [2] 16, 146). Syrup. Readily polymerises.—$B''2HCl$: crystalline powder, v. sol. water; converted by boiling water into allophanic ether.—$CN.NNa.CO_2Et$ [241°]: needles; split up by heat into NaCyO and EtN.CO.—$CN.NK.CO_2Et$. [199°]. Converted by EtI at 150° into $CN.NEt.CO_2Et$ (213°).—$HO.Cu.NCy.CO_2Et$.—$CN.NAg.CO_2Et$.

Cyanamide di-carboxylic ether $CN.N(CO_2Et)_2$. [33°]. From sodium cyanamide and $Cl.CO_2Et$ (Bassler, *J. pr.* [2] 16, 134). Prisms. Insol. water. Boiling water decomposes it into CO_2, alcohol, and cyanamide carboxylic ether.

CYANAMIDO-BENZOIC ACID $CN.NH.C_6H_4.CO_2H$ [1:3]. [above 200°]. Flat pearly needles (containing ½ aq). Sol. hot water, alcohol and ether, nearly insol. cold water and benzene. Formed by the action of cyanogen chloride on an alcoholic solution of *m*-amido-benzoic acid.

Reactions.—Heated with baryta-water to 140° it decomposes into *m*-amido-benzoic acid CO_2, and NH_3. It is not altered by boiling with water, and only slowly with NaOH. Heated to 140° alone it evolves cyanic acid leaving a white amorphous insoluble substance. Boiled with dilute HCl it is converted into *m*-uramido-benzoic acid. With ammonium sulphide it gives *m*-thio-uramido-benzoic acid. On heating the barium-salt polymeric substances are formed. It combines with aniline to form a di-phenyl-guanidine-carboxylic acid.

Salts.—The salts of the alkalis, alkaline earths, and of Zn, Hg, Ni and Co are easily soluble. Fe_2Cl_6 gives a yellow amorphous pp. $AgNO_3$ gives a white gelatinous pp. and $CuSO_4$ gives a brown flocculent pp. (Traube, *B.* 15, 2118).

DICYANAMIDO-BENZOYL *v.* vol. i. p. 155.

***p*-CYANAMIDO-PHENYL-ACETIC ACID** $CN.NH.C_6H_4.CH_2.CO_2H$. [134°]. Formed by the action of cyanogen chloride on *p*-amido-phenyl-acetic acid in alcoholic solution (Traube, *B.* 15, 2121). Colourless plates or tables. V. sol. water, alcohol and ether. It is very unstable. Dilute HCl converts it into *p*-uramido-phenyl-acetic acid. $CuSO_4$ gives a brown pp. soluble in alcohol.

CYANANILINE $(C_6H_5NH_2)_2C_2N_2$.

Formation.—By the action of aniline upon oximido-ether:

$$EtO.C(NH).C(NH).OEt + 2PhNH_2$$
$$= PhNH.C(NH).C(NH).HNPh + 2HOEt$$

(Senf, *J. pr.* [2] 35, 514).

Preparation.—1. Aniline (1 pt.) is dissolved in alcohol (5 pts.) and cyanogen is passed in (Hofmann, *A.* 66, 129; 73, 180).—2. Aniline (10g.) is dissolved in alcohol (30g.) and water (60g.) is then added. On passing cyanogen gas into the solution cyananiline separates; it is purified by solution in dilute H_2SO_4 and reppn. by NH_3 (Senf, *J. pr.* [2] 35, 514).

Reactions.—1. Dry *nitrous acid gas* passed into ether containing cyananiline in suspension forms the nitrate $B''2HNO_3$. Nitrous acid gas passed into a solution of cyananiline in 65 p.c. acetic acid forms oxanilide, (1, 3, 4)-di-nitro-phenol, and phenyl-carbamine. Nitrous acid gas passed into a solution of cyananiline in glacial HOAc forms the same products, and also di-*p*-nitro-oxanilide.—2. *Sodium amalgam* forms NH_3, aniline, and formic acid.—3. *Bromine* in chloroform solution at 0° forms unstable amorphous $C_{14}H_{13}N_4Br_5$, which is probably $(C_6H_4Br.NH.C(NH).C(NH).NH.C_6H_4Br)HBr_3$ being reduced by SO_2Aq to di-bromo-cyananiline. Bromine in boiling glacial HOAc forms di-*p*-bromo-cyananiline. Bromine-water forms tri-bromo-aniline.—4. MeI at 120° gives dimethyl-aniline.—5. *Phthalic anhydride* gives phthalanil, $C_6H_4(C_2O_2)NPh$ (Senf, *J. pr.* [2] 35, 527).

Salts.—$B''2HNO_3$: [192°]; decomposed on melting, with evolution of phenyl-carbamine.—$B''H_2Cl_2$.—$B''H_2PtCl_6$.—$B''2HAuCl_4$.—$B''H_2Br_2$.

Di-*p*-bromo-cyananiline $C_{14}H_{12}N_2Br_2$ *i.e.* $C_6H_4Br.NH.C(NH).C(NH).NH.C_6H_4Br$. [245°]. From cyananiline and bromine; or by the union of *p*-bromo-aniline and cyanogen (Senf, *J. pr.* [2] 35, 530). White plates (from alcohol).

CYANATES (METALLIC). Cyanic acid has the composition HCNO; several isomerides of this composition may exist (*v.* CYANIC ACID). The metallic cyanates are probably salts of the acid NC.OH. A polymeride of cyanic acid, $H_3C_3N_3O_3$, exists; this acid is known as *cyanuric acid.* Isomerides of this composition are possible; *cyanuric acid* very probably has the constitution $(CN)_3(OH)_3$ (*v.* p. 310), and the metallic cyanurates are salts of this acid (*v.* CYANURATES). Another polymeride of cyanic acid is also known, *Cyamelide* (*v.* CYANIC ACID).

CYANATES. Metallic cyanates are most probably all salts of the acid CN.OH. They are produced in the following among other reactions: (1) by passing cyanogen into solution of an alkali or alkaline earth; (2) by heating alkaline carbonates to low redness in cyanogen, or with mercuric cyanide; (3) by fusing alkaline cyanides or ferrocyanides with an easily reduced oxide, such as PbO_2, or with a nitrate; (4) by electrolysis of KCNAq; some cyanates are obtained from KCNOAq by double decomposition. Most metallic cyanates are soluble in water, the cyanates of Cu, Pb, Hg, and Ag are only slightly soluble. Alkali cyanates are not decomposed by heating to dull redness in dry air; in moist air they give carbonates of NH_4 and the alkali. Cyanates of the alkaline earths, and of most heavy metals, are decomposed by heat to CO_2 and cyanide of the metal (*v.* Drechsel, *J. pr.* [2] 16, 201). Acids decompose cyanates, forming CO_2 and NH_3, sometimes with a little unchanged cyanic acid; some acids ppt. solid K cyanurate from KCNOAq.

Ammonium cyanate $(NH_4)CNO$. Obtained by passing NH_3 into an ethereal solution of HCNO, or by bringing together dry NH_3 and HCNO vapour. Very soluble in water. Easily changed into its isomeride urea (Liebig a. Wöhler, *P.* 20, 369, 395; *A.* 59, 291).

Potassium cyanate KCNO. S.G. 2·05. H.F. [K, C, N, O] = 102,300; [KCN, O] = 72,000; [KCNO, Aq] = −5,200 (Berthelot, *C. R.* 91, 82).

Formation.—1. By heating KCN in air, or in presence of an easily reduced oxide.—2. By passing cyanogen into KOHAq, or over heated K_2CO_3 (Wöhler, *G. A.* 73, 157).—3. By electrolysing KCNAq (Kolbe, *A.* 64, 236).—4. By deflagrating KNO_3 with $K_4Fe(CN)_6$, or $Hg(CN)_2$, or nitrogenous charcoal (W., *G. A.* 73, 157).

Preparation. — 4 parts dry pulverised $K_4Fe(CN)_6$ are mixed with 3 parts dry pulverised $K_2Cr_2O_7$; a little of the mixture is placed in a porcelain or iron dish, which is heated considerably below redness until the mixture becomes like tinder and blackens; the rest of the mixture is then thrown in little by little, each quantity being allowed to blacken before the next is added (complete oxidation of KCN to KCNO is thus ensured). After cooling, the contents of the dish are added to successive quantities of boiling alcohol, as much being added to each quantity of alcohol as suffices to saturate the latter; the alcoholic solution is cooled, and the crystals of KCNO are dried between paper, and then *in vacuo* over H_2SO_4. The yield is about 42 p.c. of the $K_4Fe(CN)_6$ used; if carefully conducted the KCNO contains about 1 p.c. impurities (Bell, *C. N.* 32, 99; modification of method of Liebig a. Wöhler, *A.* 38, 108; 41, 289; *v.* also Clemm, *A.* 66, 382).

Properties. — Small colourless odourless laminæ, resembling $KClO_3$; fuses below redness to a colourless liquid, soluble in water, fairly soluble in boiling hydrated alcohol; insoluble in absolute alcohol.

Reactions.—1. Unchanged by *heat*; but if *water* is present the salt is decomposed to K_2CO_3 and NH_3.—2. Reduced to KCN by heating in *hydrogen*, or with *potassium*, *iron*, or *carbon.*—3. Melted with *sulphur* gives K_2S, KSCN, and K_2SO_4.—4. *Sulphuric acid* forms K_2S and KSCN with some NH_4 sulphide.—5. Heated in *hydrochloric acid gas*, KCl and NH_4Cl are formed. 6. *Sodium amalgam* reacts with a neutral solution to produce formamide $(HCO.NH_2)$.

The other cyanates have not been much studied. Insoluble cyanates, *e.g.* of Pb or Ag, may be obtained by proceeding as directed for preparation of KCNO, but exhausting the heated mass with very cold water, removing K_2CrO_4 by $Ba(NO_3)_2Aq$, and ppg. by solution of a nitrate of the metal. The following cyanates have been isolated.

Barium cyanate $Ba(CNO)_2$ (Wöhler, *A.* 45, 357). By adding alcohol to a mixture of KCNOAq and Ba acetate; crystalline.

Calcium cyanate has not been crystallised; obtained by passing HCNO vapour into milk of lime.

Cobalt-potassium cyanate $Co(CNO)_2.2KCNO$ (Blomstrand, *J. pr.* [2] 3, 207). Dark blue quadratic crystals; obtained by adding KCNOAq to Co acetate solution.

Copper cyanate, not crystallised; by mixing solution of Cu acetate and Ba cyanate.

Lead cyanate $Pb(CNO)_2$ (Wöhler, *G. A.* 73, 157; Williams, *J. pr.* 104, 255). Crystalline, nearly insoluble in hot water.

Silver cyanate AgCNO (W., *G. A.* 73, 157). By adding $AgNO_3Aq$ to KCNOAq; S.G. 4·0; somewhat soluble in boiling water; dissolved and decomposed by dilute HNO_3Aq; decomposed by heating, to Ag mixed with C and some N. Soluble in NH_3Aq, giving a double compound which loses NH_3 in the air.

Sodium cyanate NaCNO. Resembles KCNO; crystalline.

Thallium cyanate TlCNO; tablets, sol. water, insol. alcohol (Kuhlmann, *A.* 126, 78).

M. M. P. M.

CYANBENZINE *v.* *Paranitrile* of PHENYL ACETIC ACID.

CYANBUTINE *v.* *Paranitrile* of VALERIC ACID.

CYANCONIINE $C_9H_{14}N_2$. (205°). S.G. ·93. Cyanethine heated with HCl gives 'oxy-cyanconiine' (*v. infra*), whence PCl_5 forms 'chlorocyanconiine,' which is reduced to cyan-coniine. This name is given to the base by E. v. Meyer (*J. pr.* [2] 22, 286), although it is not formed in any way from coniine.

Properties.—This base dissolves somewhat in water, forming an alkaline liquid, but it separates again if the solution is warmed. It is a colourless liquid of narcotic odour. It boils at 205°. It is volatile with steam. It is poisonous, and its physiological effects resemble those due to coniine. Its aqueous solution gives with silver chloride crystalline needles of a double salt: $B'HgCl_2$, ½aq. [c. 90°].

Combinations.—1. With *ethyl iodide* at 100° forms a compound, whence by AgCl and $PtCl_4$ sharp yellow prisms of $(B'EtCl)_2PtCl_4$ may be got.—2. With *acetyl chloride* it gives unstable needles, probably B'AcCl.

Reactions.—Reduced by Zn and HCl to a new base $C_{18}H_{30}N_4$, which forms a zinc double salt (E. v. Meyer, *J. pr.* [2] 26, 340).

Oxy-cyanconiine $C_9H_{14}N_2O$. [157°]. S. ·75 at 25°. S. (alcohol of 90 p.c.) 8 at 18°.

Preparation.—1. This base is got by heating (20 g. of) cyanethine (*q. v.*) with conc. HCl (30 c.c.) for 3 hrs. at 190°. The product is evaporated, mixed with ammonia, and the pp. crystallised from water.—2. It may also be got by passing N_2O_3 into a solution of cyanethine in glacial acetic acid (v. Meyer, *J. pr.* [2] 26, 342).

Properties.—Bunches of glittering needles (from water), long striated prisms (from alcohol), or dendritic aggregates (by precipitation). May be sublimed. Sol. chloroform, benzene, and ether.

Reactions.—1. Heated with *ethyl iodide* it forms a syrup, whence by successive treatment with Ag_2O, HCl, and $PtCl_4$, trimetric crystals of $(B'EtCl)_2PtCl_4$ are formed. Hence it is a tertiary base.—2. With *acetyl chloride* forms a peculiar compound B'AcCl, not decomposed by ammonia (M.).—3. Not affected by heating with Ac_2O at 180°.—4. With PCl_5 at 140° it gives off HCl. Product shaken with solution of NaOH and extracted with ether, is found to be an oil $C_9H_{13}N_2Cl$. This reaction looks as if the base contains hydroxyl. It is converted by NH_3 at 220° into cyanethine: $C_9H_{13}N_2Cl + 2NH_3 = NH_4Cl + C_9H_{13}N_2.NH_2$. Alcoholic potash rapidly removes its chlorine forming a new base: $C_9H_{13}N_2Cl + KOEt = KCl + C_9H_{13}N_2.OEt$. The new base is an oil smelling of herbs and boiling at 230°. Its platinum salt crystallises in octahedra $(B'HCl)_2PtCl_4$. Heating with fuming HCl at 210° it is converted into the original oxy-cyanconiine: $C_9H_{13}N_2OEt + HCl = EtCl + C_9H_{14}N_2O$. These various reactions point to the presence of hydroxyl in oxy-cyanconiine and of amidogen in cyanethine. The chlorinated base $C_9H_{13}ClN_2$ may be reduced by Zn and HCl. The zinc double salt of a new base is thus got: $ZnCl_2,C_{18}H_{30}N_42HCl$. If this salt be treated with solution of NaOH and shaken with ether, the ether leaves, on evaporating, cyanconiine $C_9H_{14}N_2$, in the form of an oil. The base $C_{18}H_{30}N_4$, which is first formed in the reduction of chloro-cyanconiine, is readily oxidised by Ag_2O to cyanconiine.—5. With $ClCO_2Et$ oxy-cyanconiine forms a liquid carboxylic ether, which is decomposed by conc. mineral acids into the oxy-base CO_2 and alcohol (E. v. Meyer, *J. pr.* [2] 30, 121).

Salts.—Sol. water. Solutions acid to litmus. — B'HCl (at 110°). — $(B'HCl)_2PtCl_4$. — $B'HNO_3$.—$B'H_2C_2O_4$. Prisms.

Oxy-cyanconiine can occasionally act as an acid, for it forms a silver salt $C_9H_{13}AgN_2O$, sol. HNO_3 and NH_3.

Methyl derivative $C_9H_{13}MeN_2O$. [77°]. (276°). S. 8 at 18°. MeI (5 pts.) is heated with oxy-cyanconiine (2 pts.) at 150°. Crystals of $C_9H_{13}MeN_2O,HI$ are got. NaOH sets the base free. It forms white needles. Insol. potash.

Salts. — $(B'HCl)_2PtCl_4$: yellow trimetric prisms. — $HgCl_2B'$, $\frac{1}{2}$aq: needles grouped in stars.

Ethyl derivative $C_9H_{13}EtN_2O$. [43°]. (268°).

Salts.—$(B'HCl)_2PtCl_4$: tablets.—$HgCl_2B'$, $\frac{1}{2}$aq.

Ethylene derivative $C_2H_4(C_9H_{13}N_2O)_2$. [154°]. S. ·01 at 24°. From ethylene bromide (7 pts.) and the base (2 pts.) at 170°.

Salt.—$B''(HCl)_2PtCl_4$: prisms.

Constitution.—Since methyl-, ethyl-, and ethylene-oxy-cyanconiine are insol. strong potash, it would appear that the alkyls have entered an hydroxyl (E. v. Meyer, *J. pr.* [2] 26, 352). But this is not the hydroxyl corresponding to the Cl of chloro-cyanconiine, because the product of the action of KOEt upon it is a different body to the ethyl-oxy-cyanconiine here described. Nevertheless, EtI and MeI acting upon oxy-cyanconiine in presence of alcoholic potash form the above ethyl- and methyl-oxy-cyanconiines. The isomeric methoxy-cyanconiine from MeOK and chloro-cyanconiine boils at 225°. The ethoxy-base boils at 230°. E. v. Meyer thinks the isomerism can be explained thus:

ethoxy-cyanconiine $C_9H_{11}N_2(OEt)$
ethyl-oxy-cyanconiine $C_9H_{12}N(NEt)(OH)$.

CYANETHINE $C_9H_{15}N_3$. [190°]. S. ·073 at 17°. S. (alcohol of 90 p.c.) 5·8. According to E. v. Meyer (*J. pr.* [2] 35, 84) cyanethine is not the paranitrile of propionic acid $C_3N_3Et_3$, since this body, obtained by reducing α-di-chloro-propionic nitrile, has quite other properties.

Preparation.—Propionitrile (240 g.) is added gradually to sodium (30 g.), in a flask full of carbonic acid. A violent reaction occurs a few minutes after the addition of each portion. The excess of propionitrile is distilled off. The retort is broken up and the contents treated with water. The insoluble cyanethine is crystallised from 90 p.c. alcohol. The yield is 50 p.c. (Frankland a. Kolbe, *C. J.* 1, 69; E. v. Meyer, *J. pr.* [2] 22, 262). One third of the sodium becomes sodic cyanide; for every molecule of sodic cyanide formed one molecule of ethane is given off. If ether be used as a diluent, there is formed an intermediate product Me.CHNa.CN, which on being treated with water yields an oil which gradually crystallises, and has the same percentage composition as cyanethine, but is polymeric with it [48°] (258°). The compound Me.CHNa.CN, heated with propionitrile to 150°, yields cyanethine (E. v. Meyer, *J. pr.* [2] 37, 412).

Properties. — Monoclinic crystals (from alcohol).

Reactions.—1. With *ethyl iodide* at 160° forms B'EtI, a syrup, whence by moist Ag_2O an alkaline liquid may be got, and on adding HCl and $PtCl_4$ a well crystallised double salt $(B'EtCl)_2PtCl_4$ is obtained. But if the iodide be treated with Ag_2O, and the resulting alkaline solution be shaken with ether, the latter is found to contain ethyl-cyanethine $C_9H_{14}EtN_3$. [45°]. (260°).—2. Excess of strong *hydrochloric acid* converts it into cyanconiine $C_9H_{15}N_3 + H_2O + HCl = H_4NCl + C_9H_{14}ON_2$. It is precipitated by ammonia.—3. This same body is formed by passing N_2O_3 into a solution of cyanethine in glacial acetic acid.—4. With $ClCO_2Et$ it forms cyanethine carboxylic ether $C_9H_{13}N_2NH(CO_2Et)$. This is a solid which melts at a low temperature and boils at (247°). It is converted by boiling alkali into cyanethine, alcohol, and CO_2. Its aqueous solution gives, with $AgNO_3$, a pp. $C_9H_{13}N_2NAg(CO_2Et)$, aq. Cyanethine carboxylic ether is decomposed by aniline with formation of an anilide $C_9H_{13}N_2.NH.CO.NHPh$ [184°]. This is a very stable body, not decomposed by hot alcoholic potash, but when heated in a current of HCl it gives off phenyl cyanate, becoming cyanethine
$C_9H_{13}N_2.NH.CO.NHPh = C_9H_{13}N_2.NH_2 + CO.NPh$ (E. v. Meyer a. Riess, *J. pr.* [2] 30, 115).—5. Combines at 100° with phenyl cyanate $C_9H_{13}N_2.NH_2 + CONPh = C_9H_{13}N_2.NH.CO.NHPh$.

Salts.—B'HCl aq.—$B'_2H_2PtCl_6$.—$B'HNO_3$: large prisms, neutral to litmus.

Combination.—B'_2AgNO_3 (at 120°): crystalline pp.

Mono-acetyl derivative $C_9H_{14}AcN_3$. [59°].

Tri-chloro-cyanethine $C_9H_{12}Cl_3N_3$. [110°] Obtained by passing Cl into a solution of cyanethine in chloroform. Resembles tri-bromo-cyanethine in its properties. N_2O_3 passed into its solution in glacial acetic acid forms tri-chloro-oxy-cyanconiine $C_9H_{16}(OH)Cl_3N_2$ [132°]. This latter may be reduced by HI to the oxy-cyanconiine.

Bromo-cyanethine $C_9H_{14}BrN_3$. [153°].

Preparation.—Cyanethine (30 g.) is dissolved in HBr and an equivalent of Br (30 g.) is added. A perbromide of hydrobromide of cyanethine separates as an oil, which soon solidifies. The whole is heated in sealed tubes at 100° for 5 hours. On cooling, crystals of the hydrobromide of bromocyanethine separate. The base is got by adding NH_3 to an aqueous solution of these crystals (C. Riess, *J. pr.* [2] 30, 146).

Properties. — Needles. Penetrating odour; v. sl. sol. water.

Salts.—$B'HNO_3$. Trimetric.—$(B'HCl)_2PtCl_4$. —$B'HClAuCl_3$.—$B'HBr$.

Reactions.—1. Boiled with alcoholic NaOEt it forms ethoxy-cyanethine (*q. v.*).—2. Fuming HCl at 200° displaces amidogen by hydroxyl, the product being $C_9H_{12}BrN_2(OH)$, [171°]. The salts of this bromo-oxy-cyanconiine are decomposed by water.—3. With *aniline* at 200° it forms $C_9H_{14}(NPhH)N_3$, phenyl-amido-cyanethine. This is insol. water, but crystallises from alcohol in plates, [125°].—4. *Zinc* and HCl reduce it to cyanethine.—5. N_2O_3 passed into its solution in glacial HOAc forms bromo-oxy-cyanconiine [172°] (E. v. Meyer, *J. pr.* [2] 26, 358).

Tri-bromo-cyanethine $C_9H_{12}Br_3N_3$. [126°]. This is formed when bromine acts on cyanethine dissolved in chloroform. It forms pearly plates insol. water, sol. alcohol, ether, and chloroform. It dissolves in strong acids, but is reppd. by water. By passing N_2O_3 into a solution of the base in glacial acetic acid, the corresponding 'tri-bromo-oxy-cyanconiine' may be formed: $C_9H_{10}(OH)Br_3N_2$, [149°].

Iodo-cyanethine $C_9H_{14}IN_3$. [152°].

Preparation.—Iodine simply combines with cyanethine, forming a per-iodide. Substitution takes place in presence of HNO_3, as follows: cyanethine (1 pt.) is dissolved in excess of dilute H_2SO_4, iodine ($1\frac{1}{2}$ pt.) is added, and then the liquid is digested on the water-bath while conc. HNO_3 is run in until all the iodine has disappeared. From the filtrate NaOH throws down iodo-cyanethine.

Properties.—Sol. acids and dilute alkalis. Decomposed by boiling NaOH.

Salt.—$B',HCl,AuCl_3$.

Reactions.—1. Iodine added to its acid solutions throws down glittering green plates of a periodide.—2. Unlike the chloro- and bromo-derivatives, it is *not* affected by passing N_2O_3 into its solution in glacial acetic acid.—3. Nevertheless fuming HNO_3, acting upon its solution in glacial acetic acid, does produce iodo-oxy-cyanconiine: $C_9H_{12}IN_2(OH)$. This may be crystallised from alcohol. It melts at [157°].—4. Dilute HNO_3 or conc. HCl (at 180°) convert iodo-cyanethine into oxy-cyanconiine, $C_9H_{13}(OH)N_2$, [156°] (Riess, *J. pr.* [2] 30, 168).

Methyl-cyanethine $C_9H_{14}MeN_3$. [74°] (c. 257°). From cyanethine and MeI at 160° (E. v. Meyer, *J. pr.* [2] 26, 348). V. sol. water, forming an alkaline solution from which it may be extracted by ether. It separates as an oil when its solution, saturated in the cold, is warmed. Cyanethine itself is very slightly soluble. Methyl-cyanethine affects the brain-cells, producing muscular contraction. Chloral, chloroform, and morphia are antidotes.

Combinations. — $B'_2,AgNO_3$. Pp. sol. hot water, separating as plates.—$B',(HCl)_2PtCl_4$.

Reaction. — 1. Heated with HCl at 180° it splits up into methylamine and oxy-cyanconiine: $C_9H_{13}N_2(NHMe) + H_2O = C_9H_{13}N_2(OH) + NH_2Me$.

Methoxy-cyanethine $C_9H_{14}(OMe)N_3$, aq. [130°]. Resembles ethoxy-cyanethine in preparation, properties, and salts. It also exchanges NH_2 for OH when acted on by N_2O_3, the product being the mono-methyl derivative of di-oxy-cyanconiine $C_9H_{12}(MeO)N_2(OH)$. This forms the salts: $B',HCl,AuCl_3$.—$C_9H_{11}Ag(MeO)N_2(OH)$ (C. Riess, *J. pr.* [2] 30, 153).

Ethoxy-cyanethine $C_9H_{14}(OEt)N_3$. [115°].

Preparation. — From sodic ethylate and bromo-cyanethine (Riess, *J. pr.* [2] 30, 148).

Properties.—Trimetric plates. Sublimes at 100°. More soluble in cold than in hot water. Its solution is alkaline to test-paper. Separated by KOH from its aqueous solution. Sol. alcohol, ether, chloroform, and acids.

Reactions.—1. An aqueous solution of the free base precipitates the hydrates of copper and lead from their salts.—2. N_2O_3 passed into a solution of the base in glacial acetic acid forms the corresponding ethyl derivative of di-oxy-cyanconiine: $C_9H_{12}(OEt)N_2OH$. This melts at [51°] and forms a silver derivative, $C_9H_{11}Ag(OEt)N_2OH$.—3. Heated with conc. HCl at 200°, it appears to form di-oxy-cyanconiine: $C_9H_{12}(OH)_2N_2$ [151°], a silver salt, $C_9H_{11}Ag(OH)_2N_2$, being analysed.

Salts.—$(B',HCl)_2PtCl_4$.—$(B',HCl)AuCl_3$.

Combinations.—$B',AgNO_3$.

CYANETHOLINE *v. supposed Ethyl ether* of *Normal* Cyanic acid.

CYANHYDRIC ACID HCN. (*Hydrocyanic acid. Prussic acid. Formonitrile.*) Mol. w. 26·98. [−15°]. (For melting-points of mixtures of HCN and H_2O *v.* Gautier, *A. Ch.* [4] 17, 120). (26·5°). S.G. (Liquid) at 7° = ·7058, at 18° ·6969. V.D. ·966 at 40°, ·942 at 77°, ·936 at 96°, ·924 at 158°, ·903 at 198° (Gautier, *A. Ch.* [4] 17, 119). $\mu^D = 1{\cdot}263$ at 17° (Bussy a. Buignet, *A. Ch.* [4] 3, 231). μ_D for mixture of HCN and H_2O (17°) (B. a. B., *l.c.*); ratio $2HCN{:}H_2O = 1{\cdot}282$, $2HCN{:}2H_2O = 1{\cdot}297$; $2HCN{:}3H_2O = 1{\cdot}306$, $2HCN{:}4H_2O = 1{\cdot}308$. H.F. [C, N, H] = −27,480; $[C^2N^2,H^2] = 10{,}740$; H.C. $[CNH,O^{\frac{5}{2}}] = 158{,}620$ (*Th.* 2, 389). Heat of neutralisation [HCNAq, NaOHAq] = 2,770 (*Th.* 1, 295). H.V. = 5,700 (Berthelot, *A. Ch.* [4] 6, 432). HCy is an extremely weak acid; the affinity is so small that the compound can scarcely be classed as an acid (*v.* Ostwald's *Lehrbuch der allgemeinen Chemie*, 2, 849). Contraction of volume occurs on mixing with water; v = vol. of HCN, v′ = vol. of H_2O, v″ = vol. of mixture; then (B. a. B., *l.c.*).

Ratio of $HCN{:}H_2O$	$\frac{v+v'-v''}{v+v'}$
2:1	·0328
2:1·5	·0541
2:2	·0603
2:2·5	·0611
2:3	·0623
2:3·5	·0535
2:4	·0468

Lowering of temperature occurs on mixing with water (B. a. B., *l.c.*).

Ratio of HCN:H_2O	Fall of temp. °
2:1	8·5
2:1·5	9
2:2	9·25
2:2·5	9·25
2:3	9·75
2:3·5	8·25
2:4	7·75

Maximum contraction and maximum fall of temperature occur when the acid and water are mixed in the ratio 2HCN:$3H_2O$.

Vapour-pressure of liquid HCN at 18·25° = 472 mm. (B. a. B., *l.c.*).

Prussic acid was discovered by Scheele in 1782; it was examined by Berthollet, Proust, and others; the pure acid was prepared by Gay-Lussac in 1821 (*A. Ch.* 77, 128; 95, 136).

Occurrence.—In tobacco-smoke (Vogel a. Reischauer, *D. P. J.* 148, 231; Vohl a. Eurenberg, *A.* 147, 130). Among the products of oxidation of many carbon compounds by HNO_3 (Gill a. Mensel, *Z.* 1869. 65). As a product of the action of $KMnO_4Aq$ on thialdine and analogous compounds, also of boiling NaOHAq on aromatic nitro-compounds (Guareschi, *B.* 12, 1699; Post a. Hübner, *B.* 5, 408). As a product of the distillation with water of parts of plants containing *amygdalin* (*q.v.* vol. i. p. 205).

Formation.—1. By subjecting cyanogen and hydrogen to the electric discharge (Boillot, *C. R.* 76, 1132); or by heating the mixture to 500°-550° (Berthelot, *Bl.* 33, 2); or by dissolving cyanogen in water and allowing to stand (Wöhler, *P.* 15, 627; *v.* also CYANOGEN).—2. By the action of the induction-spark on a mixture of acetylene and nitrogen (Berthelot, *C. R.* 67, 1141; Dewar, *Pr.* 29, 188; 30, 85), or on a mixture of N with hydrocarbons which yield C_2H_2 (Berthelot, *l.c.*; Perkin, *C. N.* 21, 66).—3. By rapidly heating NH_4 formate or formamide with P_2O_5 (Lorin, *A.* 132, 255; Handl, *W. A. B.* 32, 252; 42, 747; Hofmann, *J. pr.* 91, 61).—4. By burning moist methylamine (Tollens, *Z.* 1866. 516).—5. By passing $CHCl_3$ vapour with NH_3 through a hot tube, or by heating $CHCl_3$ and alcoholic NH_3 to 180°-190° (Heintz, *A.* 100, 369); or by mixing $CHCl_3$ with KOHAq and NH_3Aq (Hofmann, *A.* 144, 116).—6. By decomposing $Hg(CN)_2$ by HClAq or H_2SO_4Aq, preferably in presence of NH_4Cl, and purifying by passing through $CuCO_3$ and $CaCl_2$ (Gay-Lussac; Bussy a. Buignet, *A. Ch.* [4] 3, 250).—7. By decomposing $Hg(CN)_2$ by H_2S, or by shaking with H_2SO_4Aq and Fe filings.—8. By decomposing AgCN by HClAq.

Preparation.—1. A cold mixture of 12 parts water with 9 parts H_2SO_4 is poured on to 8 parts coarsely powdered $K_4Fe(CN)_6$ in a capacious flask; the flask is connected with two bottles containing calcium chloride placed in a bath of cold water; the exit tube from the bottles passes into a dry flask surrounded by snow and salt. The mixture is warmed, and HCN passes into the $CaCl_2$-bottles; after about ½ hour the water surrounding the $CaCl_2$-bottles is warmed to 30° or so, when dry HCN passes into the flask in the freezing mixture, and is there liquefied (Pessina, *Traité de Pharmacie* de Soubeiran, 2, 337; *cf.* Wöhler, *A.* 73, 218). Great care must be taken, as HCN is frightfully poisonous; the $CaCl_2$ used should be dissolved (after use) in a large quantity of water, HCN is evolved during solution. If HCNAq is to be prepared, 10 parts $K_4Fe(CN)_6$ may be distilled with about 4 parts H_2SO_4 and a convenient quantity of water in a flask with very good condenser; the distillate may be rectified by distilling over MgO.—2. A solution of HCN of determined strength can be prepared by mixing KCN and tartaric acid in the ratio KCN:$H_2.C_4H_4O_6$ with a measured volume of water; HCNAq and $KH.C_4H_4O_6$ are formed, almost the whole of the latter is ppd. If 4 parts pure KCN are added to 9 parts tartaric acid in 60 parts water, and shaken in a stoppered bottle nearly filled by the liquid, and then allowed to stand for 12 hours, the liquid contains 3·6 p.c. HCN (Clarke, *A.* 1, 44; *cf.* Liebig, *A.* 41, 288).

Properties.—A mobile, colourless liquid, having a peculiar and very penetrating odour; does not redden litmus; *intensely poisonous*; one drop of the anhydrous acid is instantly fatal if swallowed. Inhalation of minute quantities of vapour suffices to kill, even when mixed with air the vapour is extremely poisonous; soluble in water, alcohol, and ether (for temperature and volume changes on dissolving in water, *v. ante*). Evaporation in air suffices to freeze part of the acid, crystals thus formed are transparent orthorhombic prisms. HCN or HCNAq is unstable; brown, humus-like products are formed (*v.* also *Reactions* No. 2); addition of traces of formic acid or a mineral acid serves to prevent this decomposition. Burns in air with blue flame. HCNAq is a very weak acid; its affinity is almost nothing; cyanides are generally very easily decomposed by acids.

Reactions.—1. Passed through a *tube heated to dull redness*, H, CN, C, and N are formed (Deville a. Troost, *J.* 1863. 307); *heated to about* 100° HCN forms a black mass, which at a higher temperature gives NH_3 and $NH_4.CN$ (Girard, *C. R.* 83, 344); passed over *red hot iron* HCN is decomposed into H, C, and N (Gay-Lussac, *A. Ch.* 95, 200).—2. Even *in the cold* HCN or HCNAq easily undergoes change; brownish, humus-like bodies are formed; according to Gautier (*A. Ch.* [4] 17, 119) perfectly pure HCN does not undergo change, but if a trace of NH_3 is present decomposition proceeds with formation of *azulmic acid* (*q. v.* vol. i. p. 429). Traces of alkali hasten the decomposition of HCN (hence if the $CaCl_2$ used for drying contain CaO the acid produced soon begins to change), traces of acids retard the change; among the products is the polymeride $H_3C_3N_3$ (*v.* TRICYANHYDRIC ACID, p. 302). In presence of water NH_4 formate is produced.—3. A series of *electric sparks* passed through HCN causes partial decomposition to N and C_2H_2 with separation of a little C, after a time the C_2H_2 and N begin to recombine. An *electric current* passed through HCNAq evolves H at the negative electrode with formation of cyanide of the metal forming the positive electrode; if the HCNAq is conc. and mixed with H_2SO_4, CO_2 and NH_3 are produced (Schlagdenhauffen, *J.* 1863. 305).—4. Mixed with *oxygen*, and brought to a flame, violent explosion occurs with production of CO_2, H_2O, N, and traces of HNO_3.—5. *Potassium permanganate* in alkaline solution oxidises

HCNAq to HCNOAq (Péan de Saint-Gilles, *A. Ch.* [3] 55, 374).—6. *Chlorine* reacts with HCN in daylight to form $C_3N_2Cl_3$; with HCNAq it forms CNCl and HCl (Bischoff, *B.* 5, 80). According to Wurtz (*A.* 79, 280) Cl also forms $C_2N_2Cl_2.CNH$; if the HCN is in alcoholic solution a crystalline compound $C_8H_{15}ClN_2O_4$ is said to be produced (*cf.* Wurtz, *l.c.* and Bischoff, *l.c.*).—7. *Bromine* forms CNBr and HBr.—8. *Iodine* with HCNAq gives CN and HIAq.—9. *Hydrogen* (nascent) forms CH_3NH_2; the same compound is produced by passing HCN vapour and H over hot spongy Pt (Menduis, *A.* 121, 129; Linnemann, *A.* 145, 38; Debus, *A.* 128, 200).—10. *Potassium* heated with HCN gives KCN and H.—11. Reaction with *water*, *v.* beginning of this article.—12. Heated with *hydriodic acid*, NH_3 and CH_4 are produced (Berthelot, *J.* 1867. 347).—13. Conc. *mineral acids* form formic acid and NH_3; *boiling solutions of alkalis* react similarly; very conc. HClAq in the cold produces formamide (Claisen a. Matthews, *B.* 16, 308); with HCl and alcohols, alkyl salts of formic acid are produced (Volhard, *A.* 176, 135).—14. With *alkalis* in solution, alkali cyanide is formed; on heating alkali formate and NH_3 are produced.—15. Some *metallic oxides* form cyanides and H_2O, *e.g.* ZnO, HgO; others give oxy-cyanides, *e.g.* PbO, CdO; some evolve cyanogen, *e.g.* PbO_2 (Liebig, *A.* 35, 3).—16. Some *metallic salts* are decomposed by HCNAq giving cyanides, *e.g.* many acetates, some salts of Ag and Cu, some alkaline carbonates.—17. *Alkali polysulphides* form sulphocyanides.

Combinations.—1. With *water* hydrates are perhaps formed, but none has been isolated; the contraction and lowering of temperature (*v.* beginning of this art.) point to formation of $2HCN.3H_2O$; the change of M. P. on addition of water seems perhaps to indicate a hydrate $HCN.H_2O$ (Gautier, *A. Ch.* [4] 17, 120).—2. With *hydrogen peroxide* to form oxamide, $C_2O_2(NH_2)_2$ (Attfield, *C. J.* [2] 1, 94).—3. With *hydrogen* to form CH_3NH_2 (*v. Reactions*, No. 9).—4. With the *haloid acids*: HCN saturated with HCl gas at −10°, and then heated to 35°-40° forms crystals of NCH.HCl, insol. ether, sol. water, alcohol, and acetic acid; the dry compound dissociates *in vacuo* (Gautier, *C. R.* 65, 410); dry HCl passed into a mixture of HCN and $C_2H_3O.OC_2H_5$ at −10° to −15° forms white prismatic crystals of 2NCH.3HCl, insol. ether, $CHCl_3$, and acetic acid, sol. water with decomposition (Claisen a. Matthews, *B.* 16, 308). The compound 2NCH.3HBr is produced similarly to the hydrochloride (Gal, *C. R.* 61, 643; Gautier, *A. Ch.* [4] 17, 141; C. a. M., *l.c.*). When HI gas is passed into HCN the compound NCH.HI is formed, crystallises from alcohol in rhombohedra, sublimes at 300°-400° with but slight decomposition; insol. ether, sol. cold water; soon changes to HI and NH_4 formate (Gautier, *C. R.* 61, 380; Gal, *C. R.* 61, 643).—5. With *metallic chlorides*: anhydrous HCN combines with several metallic chlorides with production of much heat; the compounds are decomposed by water; the following have been obtained: (1) $TiCl_4.2NCH$ (Wöhler, *A.* 73, 226); (2) $SnCl_4.2NCH$ (Klein, *A.* 74, 85); (3) $SbCl_5.3NCH$ (Klein, *l.c.*); (4) $Fe_2Cl_6.4NCH$ (Klein, *l.c.*). BCl_3 seems to form a compound with HCN (*v.* Martius, *A.* 109, 81). 6. HCN combines directly with very many *aldehydes*, *e.g.* with acetic aldehyde it forms $C_2H_4O.NCH$ (*v.* the different *aldehydes*).

Detection and Estimation.—1. Addition of KOHAq followed by $FeSO_4Aq$ containing some ferric salt ppts. Prussian blue mixed with $Fe(OH)_2$ and $Fe(OH)_3$; addition of HCl dissolves the Fe hydroxides and leaves Prussian blue. If there be very little HCN or cyanide present, a blue-green liquid is formed, which on standing deposits bluish flocks. This test will detect $\frac{1}{780}$ grain of HCN in a very dilute liquid (Taylor, *A.* 65, 263).—2. To the liquid to be tested are added a few drops of yellow NH_4 sulphide, the liquid is evaporated on the steam-bath, $(NH_4)SCy$ is thus formed; a few drops of water are added and a drop of Fe_2Cl_6Aq, when blood-red $Fe(SCy)_3$ is formed. This test will detect $\frac{1}{3930}$ grain HCN in a very dilute liquid (Taylor, *l.c.*).—3. $AgNO_3Aq$ pps. white AgCN, e. sol. NH_3Aq, unblackened by light, sol. conc. boiling HNO_3 with evolution of CO_2. Other tests are founded on (1) the insolubility of $Cu_2(CN)_2$ in dilute HClAq (Lassaigne, *A. Ch.* 27, 200); (2) the production of a blood-red colour on heating KCNAq with picric acid (Braun, *Fr.* 1864. 464; Vogel, *C. C.* 1866. 400; (3) the blue colour produced by Cu salts with tincture of guiacum in presence of HCN (Schönbein, *Fr.* 1869. 67; Vogel, *l.c.*; Eckmann, *Fr.* 1870. 429; Link a. Möckel, *Fr.* 1878. 455). Insoluble cyanides may be fused with dry $Na_2S_2O_3$, dissolved in water, and tested with Fe_2Cl_6Aq (Fröhde, *C. C.* 1863. 698). In cases of suspected poisoning, HCN is separated by distillation after acidifying the matter with tartaric acid. (For details, a manual of analysis must be consulted.)

HCN may be estimated by ppg. as AgCN, from solutions slightly acidulated by HNO_3, by addition of $AgNO_3$; haloid acids must be absent; the pp. is washed, dried at 100°, and weighed. Liebig's volumetric method may be used when haloid acids are present (*A.* 77, 102); the solution is made strongly alkaline by KOHAq, and standardised $AgNO_3Aq$ is added until a permanent turbidity is produced; the compound $AgK(CN)_2$ is produced but remains dissolved until addition of excess of silver forms insoluble AgCN. 1 c.c. of decinormal silver solution (10·8 grams Ag per litre) = ·0054 gram HCN.

Constitution. — Cyanhydric acid may be (1) HCN or (2) HNC; formula (1) represents the atom of H as directly associated with the C atom, while formula (2) represents the atoms of H and N as directly associated. The reactions of this acid with alkalis show that the H atom is acidic; the fact that the acid combines directly with the haloid acids favours the formula N.CH, which suggests the properties of a derivative of NH_3. The formation of the acid by the reaction of $CHCl_3$ with KOHAq is in keeping with the formula N.CH; this formula also suggests the production of CH_3NH_2 by the reaction of hydrogen with N.CH; the production of $H.CO_2NH_4$ when cyanhydric acid reacts with H_2O cannot decide between the formulæ N.CH and C.NH. On the whole cyanhydric acid is best regarded as the nitrile of formic acid; the formula is written N.CH.

POLYMERIDE OF CYANHYDRIC ACID. Tricyanhydric acid. $H_3C_3N_3$. Produced by spontaneous polymerisation of HCN, or of conc. HCNAq, in presence of alkalis, also from KCN (Lange, *B.* 6, 99; Wippermann, *B.* 7, 767; Lescœur a. Rigault, *C. R.* 89, 310). Prepared by treating the brown substance produced when HCN is allowed to change in air, with much ether, crystallising, dissolving in ether, shaking with animal char, crystallising, and re-crystallising from hot water. Triclinic crystals; v. sol. alcohol, less sol. ether. Solubility in water ·55 at 31°, 5–5·5 at 100°. Begins to decompose at 140°, melts at about 180°, and deflagrates at a higher temperature. When slowly heated with water forms HCN and the products of decomposition of this acid ($H.CO_2H$, NH_3, &c.). Heated with BaOAq, with HClAq, or HIAq, produces CO_2, NH_3, and glycocoll (Wippermann, *B.* 7, 767); hence tricyanhydric acid appears to be the nitrile of amido-malonic acid, $CN.CH(NH_2).CN$ (*cf.* Bæyer, *A.* 131, 297).

M. M. P. M.

DICYANHYDRIN *v.* Di-cyano-propyl alcohol.

CYANIC (SULPHO) ACID. SULPHOCYANIC ACID AND POLYMERIDES. (*Thiocyanic acid. Hydro-sulphocyanic acid. Sulphocyanhydric acid. Sulphocarbimide.*) Only one isomeride of the composition HCNS is known, and it is probably normal sulphocyanic acid HS.CN; the acid HN.CS has not been isolated although ethereal salts derived from it are known. A polymeride of sulphocyanic acid, viz. $H_2S_2N_2C_2$, is known, and the methylic salt of trisulphocyanic acid ($H_3C_3N_3S_3$) is also known (*cf.* Cyanic acid).

The metallic salts of the form MSCN are described as sulphocyanides in the article Cyanides.

Preparation.—1. Dilute solutions of HS.CN are obtained by distilling excess of a sulphocyanide with dilute H_2SO_4Aq; more conc. solutions are obtained by distilling KS.CN with conc. H_3PO_4Aq, or by the reaction of H_2S with $Hg(SCN)_2$ or $Pb(SCN)_2$ (Hermes, *J. pr.* 97, 465; Zimmermann, *A.* 199, 1). 2. Sulphocyanic acid is obtained by gently heating a small quantity of $Hg(SCN)_2$ in a stream of dry H_2S (Wöhler, *G. A.* 69, 271); explosions may occur if large quantities are used (Hermes, *l.c.*).

Properties. A colourless, strongly smelling, liquid; crystallises when surrounded by snow and salt. An aqueous solution containing 12·7 p.c. of the acid has S.G. 1·04 at 17° (Hermes, *l.c.*). HSCy is a very strong acid; the affinity is nearly equal to that of HCl (*v.* Ostwald's *Lehrbuch der allgemeinen Chemie*, 2, 849).

Reactions.—1. Decomposed by *heat* to HCN and persulphocyanic acid ($H_2C_2N_2S_3$). Stable in dilute aqueous solution (about 5 p.c.); the anhydrous acid *polymerises* on standing. On distilling the aqueous acid the greater part is vapourised unchanged.—2. Heated with *mineral acids*, is decomposed to HCN and $H_2C_2N_2S_3$, or to CO_2, NH_3, and CS_2 or H_2S; the products of decomposition vary with the concentration of the solution of HS.CN used (*cf.* Völckel, *A.* 43, 74). 3. Decomposed by *sulphydric acid* (H_2S) to CS_2 and NH_3 (Völckel, *l.c.*).—4. *Oxidisers*, *e.g.* $KMnO_4Aq$, produce HCN and H_2SO_4 (Péan, *C. R.* 46, 626).—5. With *zinc and sulphuric acid*, reacts to form H_2S, NH_3, $NH_2(CH_3)$, and $(CH_3)_2S_2$ (Hofmann, *B.* 1. 179).—6. Heated with fairly conc. *sulphuric acid*, COS and NH_3 are produced (Than, *A. Suppl.* 5, 236).—7. *Organic acids* react to form COS and amides, o sometimes nitriles, *e.g.* $HS.CN + C_2H_3O.O$ $= COS + C_2H_3O.NH_2$ (Letts, *B.* 5, 669; Kekul *B.* 6, 113).

The metallic salts of sulphocyanic acid ar described as Sulphocyanides under Cyanide The ethereal salts of normal sulphocyanic acid of the type Et.S.Cy, are described as Ethyl, &c. sulphocyanide; the ethereal salts derived fron isosulphocyanic acid, of the type Et.N.CS, ar described as Ethyl, &c., thio-carbimide.

Polymerides of sulphocyanic acid.

I. Disulphocyanic acid $H_2S_2C_2N_2$ (Fleischer, *A.* 179, 201). Prepared by adding alcoholic solution of KOH to persulphocyanic acid ($H_2O_2N_2S_3$ obtained by adding 3 vols. H_2SO_4Aq, S.G. 1·34, to conc. $NH_4.SCNAq$, and crystallising the crystals which separate from hot water); the crystals which separate are $K_2C_2N_2S_2$, they are collected and decomposed by dilute H_2SO_4Aq; the acid separates as a wax-like yellow mass, which hardens after a time. Sol. alcohol, nearly insol. water; when the solution is heated HSCN is formed.

II. Trisulphocyanic acid; this acid is not known, but its methylic salt, $Me_3S_3C_3N_3$, is obtained along with methyl thiocarbimide [Me.N.CS (*q. v.*)], by heating Me.S.Cy to 180° (Hofmann, *B.* 13, 1349).

For metallic salts of disulphocyanic acid *v.* Cyanurates and Sulphocyanurates, p. 360.

M. M. P. M.

CYANIC, DICYANIC, AND TRICYANIC ACIDS and their derivatives.—Historical Introduction.—Very soon after his inquiry into the constitution of Prussian Blue, an investigation which had enriched science with the discovery of Prussic Acid, Scheele (1786, *Opuscula* 2, 76) conducted a series of experiments with a view to determine the nature of a specimen of urinary calculus. The calculus happened to be of the acid variety. The outcome of this work was the discovery of Uric and Cyanuric or Pyro-uric acids. This is the earliest record of an oxygen compound of cyanogen. Scheele, however, did not realise that he had in his hands a hitherto unknown chemical compound. Distilling some of the calculus he obtained among other products a brown sublimate, which admitted of purification by resublimation. The properties of this sublimate are those now known to belong to cyanuric acid. Moreover, cyanuric acid may be obtained by the mode of procedure described. To Scheele the sublimate appeared to resemble succinic acid. Pearson (1798, *Tr.* 34) repeated these experiments, and observed in addition most of the characters of cyanuric acid known at the present day, but, like Scheele, this observer did not recognise the sublimate as a new substance, and was content to note its similarity to benzoic acid. Henry (1818, Thomson's *Système de Chemie*, 2, 198) was the first to point out the independent nature of the acid, and the earliest analysis was made by Chevallier and Lassaigne (1820, *A. Ch.* 13, 155).

At the same time that the cyanuric acid of Scheele was being studied, the first observations were made of three important classes of compounds—the fulminates, the cyanates, and the thiocyanates. Brugnatelli (1798, *A. Ch.* 27, 331) prepared 'Fulminating Silver,' which, however, he regarded as oxalate, and Howard (1800, *Tr.* 204) about the same time described the manufacture and properties of 'Fulminating Mercury.' That sulphur is capable of combining directly with potassium cyanide, forming 'Thiocyanate,' was first distinctly observed by Porret (1814, *Tr.* 527), the reaction having been studied previously by Buchholz (1798, *Beitrag zur Erweiterung und Berichtigung der Chemie*, 1, 88). The prediction of Gay-Lussac of a class of cyanates was verified by Vauquelin (1818, *A. Ch.* 9, 115, 22, 134), who found Ammonium Cyanate among the products of the spontaneous decomposition of cyanogen in water.

The discovery of the first compound of cyanic acid was soon followed by that of other cyanates and of the acid itself. Wöhler (1822-24, *G. A.* 71, 95; 73, 157; *P.* 1, 117) analysed many of these, including the silver salt, from which he derived the formula of the acid. A little later, when heating some cyanuric acid, this chemist noticed that a gas was given off, having a peculiar pungent odour. This proved to be free Cyanic Acid, and by a suitable cooling apparatus Wöhler succeeded in liquefying it. The free cyanic acid thus obtained was examined in an important memoir by Liebig and Wöhler (1830, *P.* 20, 369), and its constitution established so far as the exigencies of the time required. Liebig reverts to this question again in 1838 (*A.* 26, 122), pointing out that cyanic acid does not form double salts and is monobasic.

In the meantime a study of the fulminating mercury of Howard had furnished Liebig with some interesting results. These were published in 1823 (*G. A.* 75, 393) and in conjunction with Gay-Lussac in Paris in 1824 (*A. Ch.* 25, 285). From the silver salt, which was obtained in a condition sufficiently pure, the composition, molecular weight, and basicity of fulminic acid were ascertained. The free acid was, however, not isolated. Later (1838, *A.* 26, 122) Liebig points out the relation of fulminic acid to its isomerides, cyanic and cyanuric acids. It is shown to form double salts and to be dibasic.

In the hands of Berthollet (1787, *A. Ch.* 1, 35) and Gay-Lussac (1815, *A. Ch.* 90, 200) chlorine had been made to act upon prussic acid with the formation of gaseous Cyanogen Chloride. Serullas (1828, *A. Ch.* 38, 390), now employing the same agents in the presence of sunlight, obtained a crystalline solid now known to be Cyanuric Chloride. By the prolonged action of water this compound was found to decompose, forming hydrochloric acid and a new solid, named by Serullas Cyanic Acid. This cyanic acid was perceived to be quite distinct from the cyanic acid of Wöhler, but Serullas does not seem to have compared it with the pyro-uric acid of Scheele. Nevertheless, the properties noted by Serullas agree in all respects with those given by Pearson for Scheele's acid. The analysis made by Serullas, though not inaccurate for the time, entirely overlooked the hydrogen.

Wöhler made the next step forward by the discovery of a new compound, Cyanuric Acid, among the products of the action of heat on urea (1829, *P.* 15, 622). This cyanuric acid was at once compared both with the pyro-uric acid of Scheele and with the cyanic acid of Serullas. Its properties were found to agree with both of the earlier known substances, and when careful analyses were made of all three they proved to be identical. The subject is finally discussed by Liebig and Wöhler (1830, *P.* 20, 369), where it is suggested that the term cyanuric acid should be adopted for the single compound whether obtained by the distillation of uric acid (Scheele), the action of water on cyanuric chloride (Serullas), or the action of heat on urea (Wöhler), and that the name cyanic acid should be retained for the pungent liquid which Wöhler had found as a decomposition product of cyanuric acid, and of which Vauquelin had previously prepared the ammonium salt.

The question of the constitution of cyanic acid and its isomerides is the subject of another memoir by Liebig (1838, *A.* 26, 145). The basicity of cyanuric acid, which had been a matter of controversy between Wöhler and Liebig, is finally decided by the discovery of a triargentic salt, and it is shown to have the formula $H_3C_3N_3O_3 2H_2O$. The analogy is pointed out between the acids of phosphorus as elucidated by Graham (1833, *Tr.* 253) and the three isomerides:—monobasic cyanic acid $HCNO$, dibasic fulminic acid $H_2 2CNO$, and tribasic cyanuric acid $H_3 3CNO$.

The Thiocyanic Acid, of which Porret prepared the potassium salt, was isolated by Wöhler in 1829 (*C. A.* 69, 271), and in the same year Liebig (*P.* 15, 563) came across a solid substance among the products of the action of water on cyanuric chloride which, in conjunction with Wöhler, he found again (1830, *P.* 20, 386) as a product of the decomposition of cyanic acid with water. This compound isomeric with cyanuric acid, but insoluble, was called 'insoluble cyanuric acid' or, later, Cyamelide.

About this time, too, Liebig (1834, *A.* 10, 10) by acting on ammonium thiocyanate by heat produced a substance called Melam, and from this, by the action of dilute soda, a base was formed richer in the elements of ammonia. This base was regarded by Liebig as the amide of cyanuric acid, and was called from its parent substance Melamine (1834, *A.* 10, 18). Another base nearly related to these, Mellone, was obtained by the action of heat on melam, and from mellone, by treatment with nitric acid Liebig (1834, *A.* 10, 34) prepared an acid, Cyanilic Acid, which proved to be an isomeride of cyanuric acid, distinguished from the latter acid chiefly by its crystalline form and solubility.

The thirty-five years following 1840 were very largely devoted to the discovery of ethereal derivatives of cyanic and cyanuric acids, and to a study of their structure with a view to rendering intelligible the very remarkable metameric series of compounds which were brought to light. But aside from this main current of research there are many other discoveries of scarcely less importance. Two of these call for attention at once—the study of the action of heat on nitrate of urea by Pelouze (1842, *A.* 44, 106) and Wiedemann (1848, *A.* 68, 324), and the interesting reaction between cyanic acid and aldehyde whereby Liebig and Wöhler (1846, *A.* 59, 296) prepared the compound known as Trigenic Acid.

Three important series of alkyl derivatives were discovered during the years 1847-48; the cyanic and cyanuric ethers of Wurtz, and the thiocyanic ethers of Cahours. By acting on alkyl potassium sulphate with a salt of cyanic acid, Wurtz (1848, *C. R.* 26, 368; 27, 241) obtained Alkyl Cyanates, and using a cyanurate instead of a cyanate he succeeded in preparing a series of Alkyl Cyanurates. Both these classes of ethers when decomposed by water, in presence of dilute acids or alkalis, give amines and carbon dioxide, showing that they have a similar structure. The discovery of the ethers of Wurtz was partly anticipated by Cahours (1847, *A. Ch.* 18, 261), who by the analogous reaction of alkyl calcium sulphate with potassium thiocyanate obtained Alkylthiocyanates. The thiocyanic ethers do not admit of their constitution being studied by decomposition with water, but the same end is attained if they be subjected to the reducing action of nascent hydrogen. The thio-ethers of Cahours give by this treatment mercaptan and hydrocyanic acid, showing that the alkyl radicle is attached to the sulphur and not to the nitrogen.

The study of ethereal derivatives must now give way to the consideration of several new reactions which were brought to light at this time. Debus (1849, *A.* 72, 18) in his work on ethyl thiocarbamate or xanthogenamide $NH_2.CS.OEt$ or $NH_2.CO.SEt$ was led to the discovery of a reaction by which this compound breaks down into mercaptan and cyanuric acid. If the constitution of xanthogenamide were better known, an important insight might thus be obtained into that of cyanuric acid. Notwithstanding the attempts of Bineau (1839, *A. Ch.* 70, 251) to prepare an amide of cyanic acid homologous with the cyanuramide or melamine of Liebig, no such compound was isolated until Cloez and Cannizzaro instituted their inquiry in 1851 (*C. R.* 32, 62). These chemists obtained Cyanamide by acting upon cyanogen chloride with ammonia. A very remarkable property of the cyanamide thus obtained is the ease with which it undergoes polymerisation. The result of this intramolecular rearrangement, as shown by Beilstein and Geuther (1858, *A.* 108, 99; 123, 241) is the formation of the dicyanogen homologue Dicyandiamide. An isomeric series of homologous amides is thus completed corresponding to the three classes of mono-, di-, and tri- cyanogen compounds. Employing amines instead of ammonia in the reaction of Cloëz and Cannizzaro, the alkyl cyanamides were prepared by Cahours and Cloëz (1854, *C. R.* 38, 354).

Another instance of polymerisation was announced at this time by Liebig (1855, *A.* 95, 282). When fulminating mercury is allowed to stand in presence of water it gradually changes its colour and other properties. These changes were found to correspond to an entire rearrangement of the molecule, the dicyanic fulminic acid having polymerised to tricyanic Fulminuric Acid. The new acid is metameric with cyanuric acid, but in its basicity and in other respects it is quite distinct from that compound. Fulminuric acid was discovered independently by Schischkow (*A.* 97, 53; 101, 213), whose attention was also directed to the constitution of the isomeric fulminic acid from which it is derived. Mercuric fulminate, according to Schischkow (*J. R.* 16, 276), is $Hg(CN)_2.C_2(NO_2)_2.Hg$, and fulminic acid $(HCN)_2.C_2H_22NO_2$. On the other hand Kekulé (*A.* 101, 200; 105, 279), in view of other reactions, regarded fulminic acid as nitro-acetonitril CH_2NO_2CN.

Returning once more to the ethers, a reaction must be noticed that was first studied by Cloëz (1857, *C. R.* 44, 482), which in the hands of Hofmann and other later investigators has done much to give order to the knowledge of cyanic derivatives. Cloëz caused cyanogen chloride to act on sodium ethylate, and obtained a compound which he called Cyanetholine and which has sometimes been regarded as consisting of a cyanic ether isomeric with that of Wurtz. Gal (1866, *C. R.* 61, 527), who observed its decomposition products, correctly so regarded it, and moreover judged that it was related to the cyanic ethers of Wurtz in the same manner that the nitriles are related to the isonitriles.

Still another reaction was announced at this time for the preparation of ethers. Habich a. Limpricht (1859, *A.* 109, 111) discovered that silver cyanurate and alkyl iodides react, forming cyanuric ethers identical with those of Wurtz.

The Cloëz reaction was now, in 1870, the subject of an important investigation by Hofmann and Olshausen (*B.* 3, 269). No cyanic ether was found, but, instead, these observers succeeded in preparing a series of Cyanuric Ethers metameric with those of Wurtz. The methyl analogue of the cyanetholine of Cloëz and Gal proves to be a mixture containing cyanuric ether and an amido- derivative. Cyanic ethers homologous with these cyanuric ethers and metameric with the cyanic ethers of Wurtz have never been isolated. Hofmann and Olshausen were led to predict the formation of a series of cyanuric ethers in this reaction from its analogy to that of Cloëz and Cannizzaro for cyanamide and Cahours and Cloëz for alkyl cyanamides, thus:—

$Cl\boxed{CN+(NH)H}H$ (Cloëz and Cannizzaro)

$Cl\boxed{CN+(NH)Et}H$ (Cahours and Cloëz)

$Cl\boxed{CN+OEt}H$ (Hofmann and Olshausen).

Now in the second reaction the alkyl cyanamide was known to polymerise readily at the moment of its formation to alkyl melamine. Just in the same manner, thought Hofmann and Olshausen, might the product of the third reaction, which differs only in containing oxygen for imidogen, polymerise at the moment of its formation to a cyanuric ether. This hypothesis was confirmed by experiment.

The cyanuric ethers thus obtained when submitted to the action of water in presence of dilute acids or alkalis give cyanuric acid and alcohol, showing that the alkyl radicle is attached to the oxygen and not to the nitrogen, as it would seem to be in the case of the Wurtz ethers. It would thus appear that the Wurtz ethers are substituted imide compounds, while those of Hofmann and Olshausen are substituted hydroxyl derivatives. The reaction of both with water then becomes clear, thus:—

Hofmann and Olshausen.	Wurtz.
$C_3N_3 3OR'$	$C_3O_3N_3R'_3$
$\underline{O_3H_3H_3}$	$\underline{O_3H_6}$
$(CN)_3 3OH \mid 3R'OH$	$3CO_2 \mid 3NH_2R'$

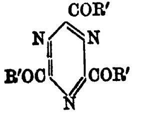
The difference between these two classes of ethers may be represented by the formulæ:—

$$(CN)_3\begin{cases}OR'\\OR'\\OR'\end{cases}$$

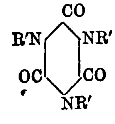
$$(CO)_3\begin{cases}NR'\\NR'\\NR'\end{cases}$$

or better still by the use of ring formulæ, a device which is especially useful when more complex reactions have to be studied. The ether corresponding to the hydroxyl acid is of course the normal or ortho-ether, while the imide substituted ether is the iso-ether:—

Normal ether of Hofmann and Olshausen.



Iso-ether of Wurtz.



In the same manner the normal cyanic ether which in the Cloëz reaction is probably formed in the first instance, but which has not been isolated, may be supposed to be related to the cyanic ether of Wurtz:—

$(CN).OR'$
Hypothetical normal cyanic ether.

$(CO){:}NR'$
Isocyanic ether of Wurtz.

And the decomposition by water of the two ethers may be represented:—

$$\begin{array}{c}CNOR'\\HOH\\\hline (CN)OH\,|\,R'OH\end{array}$$

Decomposition of hypothetical normal ether.

$$\begin{array}{c}CONR'\\OH_2\\\hline CO_2\,|\,NH_2R'\end{array}$$

Decomposition of iso-ether.

A very interesting instance of intramolecular change was announced by Hofmann and Olshausen in this same memoir. It was noticed that the melting-point of trimethyl normal cyanurate changed on continued heating. In the first place it melts at 132°, but after heating for some time the melting-point rises and remains constant at 175°. Metastasis was suspected, and it was found that, while before the application of heat the cyanurate gave when decomposed with water alcohol and cyanuric acid, after that operation its decomposition products were carbon dioxide and amine. The normal ether had changed into the corresponding iso-ether of Wurtz. Such instances of intramolecular migration from normal to iso- in the case of alkyl derivatives of cyanogen compounds are now known to be of frequent occurrence.

Of the thio-analogues of these isomeric ethers, one series had been discovered by Cahours. On reduction with nascent hydrogen they gave mercaptan and hydrocyanic acid. These were the analogues of the hypothetical normal cyanic ethers. The series of isomeric thiocyanates corresponding to the cyanic ethers of Wurtz were synthesised by Hofmann (1868, *B.* 1, 25 a. 169; 2, 452; 7, 814; 8, 106), and constitute the 'mustard oils' of which ordinary mustard oil is a member. When the mercury salt of monoalkyldithiocarbamic acid is distilled it loses mercuric sulphide, and sulphuretted hydrogen and alkyl thio-isocyanate passes over. The thio-isocyanic ethers give on treatment with nascent hydrogen not mercaptan and hydrocyanic acid but amines and thio-aldehyde. The two reactions may be seen thus:—

Normal thio-ether of Cahours.

$$\begin{array}{c}CN.SR'\\H\quad H\\\hline CNH\,|\,R'SH\end{array}$$

Isothio-ether of Hofmann.

$$\begin{array}{c}CS{:}NR'\\H_2\quad H_2\\\hline HCHS\,|\,NH_2R'\end{array}$$

The following discoveries also belong to this period:—The production of isocyanic ethers from isonitriles by direct oxidation accomplished by Gautier (1869, *C. R.* 67, 804). The discovery of Dicyanic Ethers and Alkyl Melamines by Hofmann (1861, *A. Suppl.* 1, 51; *B.* 3, 765; 1869, *B.* 2, 602; 3, 264). The former by polymerisation of phenyl-isocyanate in presence of triethylphosphine, and the latter by desulphurisation of monoalkylthio-urea in which case alkyl cyanamide is doubtless first formed and then changed into the polymeric melamine. Finally, the experiment of Beilstein (1860, *A.* 116, 357), which showed that cyanuric acid treated with phosphorus pentachloride gives cyanuric chloride. Cyanuric chloride is thus seen to be related to cyanuric acid precisely in the same way as acetyl chloride for example is related to acetic acid. It may be obtained from the acid by substitution of its hydroxyl by chlorine when treated with phosphorus pentachloride, and, as Serullas was the first to show, the chloride by treatment with water loses its chlorine and again assumes hydroxyl in its place, becoming cyanuric acid.

A period is now reached, commencing about the year 1875 and extending to the present day, during which the activity of investigators in this subject has been directed in the main to the question of the constitution of cyanic and cyanuric acids. To these must be added melamine, for just as the acids give rise each to two parallel series of metameric ethers, so, as it will appear, does melamine. This isomerism has not yet been found among the alkyl cyanamides or dicyanic diamides. It will be seen that in the case of the parent hydrogen compounds no reactions have been discovered which permit, as in the case of their alkyl derivatives, the assertion that the one is normal or of the hydroxyl type, and the other iso- or of the imide type.

The discussion was inaugurated by Nencki (1876, *B.* 9, 232), who, working on the compound aceto-guanidine, found that by a series of reactions it is converted finally into cyanuric acid. In a second communication (*B.* 9, 244) he suggested an explanation of these reactions assuming the imide nature of cyanic acid. This procedure led of course to the view that cyanuric acid is iso- or imide in its constitution. Further evidence in favour of the imide structure of both cyanic and cyanuric acids is found according to Fleischer (*B.* 9, 436) in the desulphurisation of ammonium thiocarbamate $NH_2.CO.SNH_4$ by which reaction either urea or iso-cyanate should result: experiment showed that ordinary ammonium cyanate was formed. Weith (*B.* 9, 454) then joined the controversy, and proposed an altogether new set of formulæ for the compounds obtained by Nencki from aceto-guanidine. Nevertheless, while pointing out that the imide nature of the acids was not proven, he considered the weight of evidence to be in favour of that view. Michler (*B.* 9, 715) advanced another reaction to support the iso-theory, the distillation of *u*-diphenylurea, which yields cyanic acid and diphenylamine. This reaction has, however, no more value as proof than the action of heat on urea itself.

So far the evidence had been very largely in favour of the iso-hypothesis. Claus (*B.* 9, 721) now joined issue with the preceding observers. He questioned the value of the little understood guanidine reactions of Nencki as proof of constitution, and showed, as Weith had indeed already done, that with equally probable assumptions the changes observed by Nencki might be explained so as to support the opposite view. Similarly he contended against Fleischer that the formula for ammonium thiocarbamate is by no means established, and if the alternative hydroxyl formula, $NH_2.CS.ONH_4$, be used, the reaction supports the normal hypothesis. To these criticisms both Nencki and Fleischer replied, Fleischer (*B.* 9, 988) defending the formula which he had employed for thiocarbamic acid, and Nencki (*B.* 9, 1008) considering at length the evidence for and against the two contending theories. The leading points are as follows: *For the imide or iso- formula.*—1. The easy breaking down of cyanic acid by the action of water into ammonia and carbon dioxide $CONH + OH_2 = CO_2 + NH_3$.—2. The conversion of cyanic acid into formamide by the action of nascent hydrogen $CO:NH + H_2 = H.CO.NH_2$.—3. The reaction of Wurtz in which cyanates and cyanurates yield iso- and not normal ethers $(CON)K + KR'SO_4 = CONR' + K_2SO_4$. *For the hydroxyl or normal formula.*—1. If in order to explain all the reactions of these bodies it is found necessary to assume an intra-molecular change, it is easier to imagine it taking place from the normal to the iso- than from the iso- to the normal atomic arrangements, since it is known with what ease normal cyanic and cyanuric derivatives change to the iso- condition, and thus to suppose that in the Wurtz reaction normal ether is at first formed and that it immediately changes to iso-ether.—2. Finally, Beilstein had shown that cyanuric chloride, the normal structure of which does not admit of question, is the chloride corresponding to cyanuric acid. Nencki admits that the acetoguanidine reactions tell equally for both theories. Nencki concludes, however, with Weith that the weight of evidence is in favour of the imido structure. The discussion was continued by Claus (*B.* 9, 1165), Fleischer (*B.* 9, 1459), and Nencki (*B.* 9, 1552), but little further advance was made.

The fundamental distinction between mono-, di-, and tri-cyanic acids which Liebig so clearly pointed out has been confirmed, and its value appreciated more and more. It may be that fulminic acid is not the dicyanic acid homologous with cyanic and cyanuric acids, and that this has yet to be discovered. Indeed, there may be many such mono-, di-, and tri-cyanogen series to which the numerous isomerides of cyanic acid of which the constitution is at present so little known will contribute members.

By the help of this conception a place is ready for the Thiodicyanic Acid discovered in 1876 by Fleischer (*A.* 179, 204), and perhaps for several new isomerides of cyanic acid which have now to be noticed. It was just at this time that Herzig (*B.* 12, 170) announced the discovery of α- and β-Cyanuric Acids. These new acids were said to be obtained by the action of hexabromacetone on urea. It has, however, recently been shown (Senier, *C. J.* 49, 693; 49, 743) that both these acids are merely ordinary cyanuric acid disguised by traces of impurities. The isomerism of the cyanamido-carbonic acid discovered by J. Meyer (1878, *J. pr.* 18, 419) is merely coincidental, that compound having nothing further in common with cyanuric derivatives. Four isomerides, however, remain to be noted, all derived from fulminic acid. The first is Isofulminuric Acid. It was prepared by Ehrenberg (1884, *J. pr.* 30, 38) by acting on an ethereal solution of free fulminic acid with ammonia. The remaining three isomerides were discovered by Scholvien (1885, *J. pr.* 32, 461), and all arise out of the action of dilute sulphuric acid on fulminates. They are Meta-fulminuric Acid, β-Isofulminuric Acid, and Iso-cyanilic Acid. Metallic salts of each were described, but no alkyl or other derivatives.

In the present state of their history it would be premature to speculate as to the constitution of this remarkable group of isomerides. It may, however, be worth while to bear in mind that the possible metamerides of cyanuric acid are very great, especially when mixed types are considered, as, for instance, the two conceivable intermediate acids between normal and iso-cyanuric acid (*cf.* Senier, *Inaug. Dissert.*, Berlin, [1887] 28).

A further study of these fulminuric acids may help to clear up the constitution of fulminic acid itself, for like the latter acid some of them evolve hydroxylamine when decomposed by water in presence of hydrochloric acid. It was on this account that Steiner (1883, *B.* 16, 1481) suggested the following isonitroso-formula for fulminic acid $\begin{matrix} C{=}NOH \\ \| \\ C{=}NOH \end{matrix}$, whereas he had previously (1876, *B.* 9, 782) been an adherent of Kekulé (1857, *A.* 101, 200; 105, 279), who regarded it as nitroacetonitrile. The recent work of Divers ([1885] *C. J.* 47, 79) has led to another formula $O\left\langle\begin{matrix} N{=}CH \\ \quad | \\ N{=}COH \end{matrix}\right.$. According to Armstrong, the essential facts are best represented for the present by one of the following, $N\left\langle\begin{matrix} C{-}OH \\ | \\ C{=}N.OH \end{matrix}\right.$ or $\begin{matrix} N{=}CH \\ | \quad | \\ O{-}C{=}N.OH \end{matrix}$ (*C. J.* 47, 79).

In the next place two announcements call for notice which have an interesting bearing on the constitution of cyanuric acid. The first is the production of melanurenic acid, a derivative of cyanuric acid, by Bamberger, by the action of water on dicyandiamide (*Inaug. Dissert.*, Berlin 1880; *B* 16, 1074; 16, 1459; 16, 1703). Bamberger ascribes to dicyandiamide the formula $C:NH.NH_2:NHCN$ as preferable to Baumann's formula (1873, *B.* 6, 1375), $(CNH)\left\langle\begin{matrix} NH \\ NH \end{matrix}\right\rangle(CNH)$. The second is the study of the absorption spectrum of cyanuric acid which led Hartley (1882, *C. J.* 41, 48) to the conclusion that it has a ring formula and doubly-linked atoms. This is of

course quite in accord with the normal or hydroxyl theory.

There remain to be considered the important researches of Hofmann, Klason, Ponomareff, Mulder, and Rathke. These investigations are for the most part contemporaneous. They also largely supplement one another; and although they do not explicitly support the same hypothesis, they do not take the form of a discussion. Only an outline of the more important features of this work can be attempted here.

Commencing with Mulder in the year 1882: the Cloëz reaction was the first to engage the attention of this observer (*R.* 1, 41, 191; 2, 133; 3, 287). The results in the ethyl series were similar and parallel to those in the methyl series of Hofmann and Olshausen. The most interesting observation is that normal cyanic and cyanuric ethers give bromine addition compounds, while the isocyanic and cyanuric ethers form no such combinations. This, according to Mulder, becomes a test by which the one structure can be distinguished from the other. Now cyanuric acid does not combine with bromine, and hence it is regarded as iso- in constitution. The compound with cyanuric ethyl ether has the formula $C_3N_3O_3Et_3Br_6$. By the use of this test Mulder was led in 1885 to recognise the diethyl cyanuric ether of Habich and Limpricht as an iso- compound (*R.* 4, 91). Subsequent observation has, however, not confirmed the value of this reaction as a test in all cases.

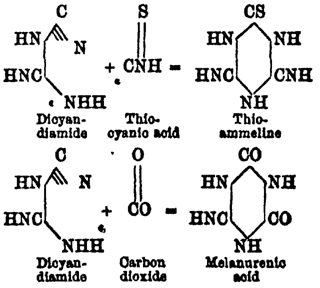
Many attempts have been made to discover among the metallic cyanates and cyanurates isomeric differences like those found among the ethers. An investigation of Calmels in 1884 (*C. R.* 99, 239) would seem to show that metallic cyanides analogous to the nitriles and carbamines exist, but hitherto no one has found evidence of a similar isomerism among the metallic cyanates or cyanurates. The experiments of Mulder in 1882 (*B.* 15, 69) with this object proved as fruitless as those of Bannow (1871, *B.* 4, 254; 13, 2201) had been.

Mulder suggested new formulæ for bromide and chloride of cyanogen N_33CBr and N_33CCl, and in a series of communications in 1885–6 (*R.* 4, 47; 4, 151; 5, 65; 5, 84; 5, 99) studied the properties of the bromide. The curious fact was noted that pure cyanogen bromide does not polymerise, but that this change takes place readily in presence of a trace of free bromine. Two curious addition products of cyanogen bromide with ethyl cyanurate are described $C_3N_3O_3Et_32BrCN$ and $C_3N_3O_3Et_3BrCN$ (*cf.* Senier, *Inaug. Dissert.*, Berlin, 1887, 34).

As in the case of Mulder, so the work of Ponomareff commenced with a study of the cyanetholine of Cloëz. This chemist in 1882 (*B.* 15, 513) arrived at results in accordance with those of Hofmann and Olshausen, and proposed the use of mercuric chloride to distinguish iso- from normal cyanuric compounds. This reagent gives crystalline addition compounds with normal derivatives, that in the case of normal ethyl cyanurate being $(CN)_33OEt,HgCl_2$. Unfortunately, like the corresponding bromine test of Mulder, this mercuric chloride test has been shown to be inapplicable to all cases (Hofmann, 1885–6, *B.* 18, 2796; 19, 2093).

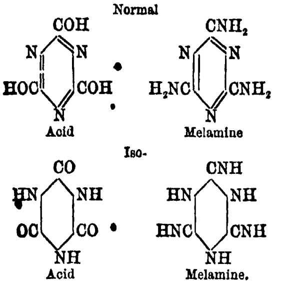
The study of the formation of cyanuric ethers and the preparation of alkoyl derivatives in the hands of Ponomareff threw additional light on their structure. Hofmann and Olshausen had prepared the cyanuric ethers by the Cloëz reaction, using cyanogen chloride. The method was simplified by Ponomareff in 1885 (*B.* 18, 3261), who employed the already polymerised cyanuric chloride. By this means he obtained normal cyanuric ethers which gave cyanuric chloride again when treated with phosphorus pentachloride, and gave melamine by the action of ammonia. In the next place this observer studied the reaction of Habich and Limpricht, by which only isocyanuric ethers had been obtained. By allowing the alkyl iodide to act on silver cyanurate at a low temperature there was always formed together with the isocyanurate some ether that gave a crystalline compound with mercuric chloride, and hence was judged by Ponomareff to be normal ether. The experiment was afterwards repeated by Hofmann and the crystalline mercuric chloride compound examined (1886, *B.* 19, 2093), but it was proved that the mercuric chloride was combined not with normal but with iso- ether. In the same memoir Ponomareff described the first alkoyl derivative of cyanuric acid, triacetyl cyanurate. The corresponding tribenzoyl cyanurate was obtained soon afterwards by Senier (1886, *C. J.* 49, 313).

The reaction between dicyandiamide and carbon dioxide already pointed out as giving rise to a mixed cyanuric acid and melamine, melanurenic acid, was made the basis of an interesting communication from Rathke in 1885 (*B.* 18, 3102). This inquirer noted that when such compounds as H_2O or NH_3 or CO_2, which can divide into two divalent radicles, for instance $H_2 + O$, $H_2 + NH$, and $O + CO$, combine to form addition compounds with cyanogen derivatives, they do so in accordance with a general law, the one residue joining the carbon and the other the nitrogen. Thus nitriles take up the residues of water or sulphuretted hydrogen, giving acid amides or thio-amides, or they take up ammonia or amines forming amidines. To this class of reactions belongs, according to Rathke, the conversion of dicyandiamide into melanurenic acid, and also the parallel reaction announced for the first time between dicyandiamide and thiocyanic acid, where combination to thioammeline takes place. Using Bamberger's formula for dicyandiamide, the reactions may be represented thus:—



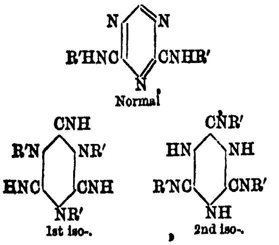
The bearing of these reactions on the constitution of cyanuric acid and melamine is evident.

Ammeline and melanurenic acids are amido-acids between melamine and cyanuric acid, and if the above expressions be the true ones, both the acid and melamine are imido- or iso- and not normal compounds. The following formulæ showing cyanuric acid and melamine both as normal and iso- compounds will assist in making this clear:—



According to Hofmann the weight of evidence is in favour of the view that both these compounds are normal in constitution. Rathke pointed out that these two reactions must be considered, and whether the formula of Bamberger be employed or the alternative one of Baumann, they both lead to the conclusion that thio-ammeline and melanurenic acid are iso-compounds, and indirectly to the iso- nature of cyanuric acid and melamine. One class of reactions requires the one formula, another class of reactions the other. In Rathke's view it is impossible to find a formula to account for both classes of reactions. It seems that the position of the hydrogen atoms, unlike that of the alkyl radicles, is not stable, and that indeed both formulæ may be employed side by side. In the same manner Rathke recommends the use of two formulæ for hydrocyanic acid, acetacetic ether, the lactam and lactim groups, thio-urea, and other similar cases.

In another communication (1887, *B.* 20, 1056) this standpoint was developed further, and in view of the discovery of several triphenylmelamines Rathke suggested the addition of a third imide type for alkyl melamines, thus:—



The radicles attached directly to the ring as in the first iso- form are said to be in the *eso*- position, while those attached to side chains as in the second iso- form are termed *exo*-. This system was suggested in order to account for the instances of complex isomerism in the case of phenylmelamines, which Hofmann was the first to point out. In the communications following, Rathke ([1887-8], *B.* 20, 1065; 21, 867; 21, 874) announced several new complex derivatives, the constitution of which he studied by means of this hypothesis. These are Phenyl Thiammeline, Triphenyl Ammeline, Monophenyl Iso-cyanuric acid, Diphenyl Melamine, and Triphenyl Melamine.

No inquirer in this department of chemical research has been more unwearied, and none has been more successful, than Hofmann. As early as 1857, in conjunction with Cahours (*A.* 102, 293), he discovered allyl cyanate, and from that time to this he has reverted to the subject again and again. The earlier communications have been already noticed, but there remain a series of exhaustive critical memoirs which have appeared during the last few years of which only the barest outline can be given. They are an attempt to settle the question of the constitution chiefly of cyanuric acid and melamine, but they bring into their service numerous new reactions and classes of compounds.

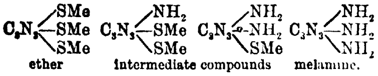
In one of the first of these, in 1881 (*B.* 14, 2728), Hofmann described a new reaction in which iso-ethers are among the products. It is the action of heat on alkyl acetyl urea. Together with isocyanic ether di- and tri-alkyl isocyanurate are formed. In another paper in 1880 (*B.* 13, 1349) some interesting instances of intramolecular change are described. Just as the cyanic methyl ether at first formed in the Cloëz reaction was found by Hofmann and Olshausen to polymerise to methyl cyanurate, so the same change is now effected in the case of methyl thiocyanate, which is converted into methyl thiocyanurate, and also (1885, *B.* 18, 765) in that of phenyl isocyanate, which becomes phenyl isocyanurate. The general tendency of the normal to pass over into the more stable iso- atomic arrangement finds another example here, for together with the trimethyl-thiocyanurate some of the iso- compound is always formed. Hofmann called attention to the fact that pure methyl-thiocyanate does not polymerise by heat alone, but does so in presence of a little hydrochloric acid. It will be remembered that in the same manner Mulder found that cyanogen bromide only admitted of polymerisation when mixed with some other substance, as, for instance, with free bromine. The action of such agents as hydrochloric acid and free bromine in these instances, and the still more remarkable action of triethylphosphine or pyridine (Snape, 1886, *C. J.* 49, 254), which convert phenyl isocyanate only into dicyanate, while if certain dry salts are substituted, sodium acetate, sodium formate, or sodium carbonate, the intramolecular re-arrangement goes as far as the production of cyanurate; these are facts of which chemistry in its present state of development offers no explanation.

From methyl-thiocyanurate thus obtained Hofmann isolated in 1885 for the first time free Thiocyanuric Acid (*B.* 18, 2196). The methyl ether, by treatment with sodium sulphide, is converted into the sodium salt, methyl mercaptan being formed at the same time, and the sodium salt, when treated with hydrochloric acid, has its sodium replaced in three stages, forming two intermediate acid sodium thio-cyanurates, and finally free thio-cyanuric acid. The sodium salt of thiocyanuric acid may be also prepared from cyanuric chloride by the action of sodium mercaptide.

Pursuing the inquiry still further into the behaviour of this thio- analogue of cyanuric acid, the action of ammonia and amines on the trimethyl ether was investigated in 1885 (*B.* 18, 2755). Water decomposes the ether in accordance with the general reaction into cyanuric acid and mercaptan, and it was thought that ammonia might similarly give mercaptan and melamine, thus:—

$$(CN)_3 3SMe + 3H(HO) = (CN)_3 3OH + 3MeSH$$
$$(CN)_3 3SMe + 3H(NH_2) = (CN)_3 3NH_2 + 3MeSH\cdot$$

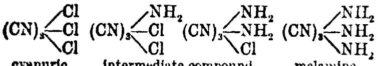
Experiment proved this to be the case. Melamine is thus advantageously prepared. The reaction takes place, however, in three stages, two intermediate compounds being formed — mono-amido- and di-amido- ether—thus:—



ether intermediate compounds melamine.

The action of substituted ammonias was now tried, and corresponding alkyl melamines and intermediate alkyl amido- ethers resulted.

Melamine and alkyl melamines are also produced, as was expected, from cyanuric chloride, and ammonia or amines, and in this case, too, a series of intermediate amido- and alkyl amido- cyanuric chlorides was obtained, thus:



cyanuric chloride intermediate compounds melamine.

The second of these intermediate compounds was identified as Liebig's chlorcyanamide (1834, *A.* 10, 43), and its phenylamido- analogue as the compound described by Laurent (1848, *A. Ch.* [3] 22, 97) under the name chlorcyanilide.

The alkyl melamines obtained by these reactions were at once compared with those which Hofmann had himself prepared sixteen years before by desulphurisation of substituted thio-ureas, and were found to be metamerides. Here, then, were two metameric series of alkyl melamines just as there are two series of alkyl cyanates and cyanurates and their thio- analogues. One might be normal and the other iso-, corresponding to the normal and iso- cyanates or cyanurates. Their constitution was now to be solved. It was feared that the action of water would give no clue to the structure of these compounds, because on the assumption of either constitution cyanuric acid and amine would probably be produced. Thus:

$$\underset{\text{alkyl-}n\text{-melamine}}{(CN)_3 3NHMe} + 3H_2O = \underset{\text{cyanuric acid}}{(CN)_3 3OH} + \underset{\text{amine}}{3NH_2Me}$$

$$\underset{\text{alkyl-iso-melamine}}{(CNMe)_3 3NH} + 3H_2O = \underset{\text{cyanuric acid}}{(CO)_3 3NH} + \underset{\text{amine.}}{3NH_2Me}$$

It is true that in the one case the acid at first formed ought to be normal and in the other iso-, but all experience had shown that, whatever might be the constitution of the acid in the first moment of its existence, it was always found when examined to be one and the same cyanuric acid. Experiment confirmed this expectation, and it became necessary to seek some other method.

This was found by Hofmann in 1885 (*B.* 18, 2781) in a reaction between cyanuric chloride and secondary amines. In this reaction neither melamine nor its primary alkyl derivatives, but secondary alkyl melamines were produced — Hexa-alkyl Melamines. These were prepared, and it was seen that an examination of the decomposition products when acted upon by water would decide whether they were normal or iso- compounds. Thus:

$$\underset{\text{alkyl-}n\text{-melamine}}{(CN)_3 3NMe_2} + 3H_2O = \underset{\text{cyanuric acid}}{(CN)_3 3OH} + \underset{\text{secondary amine}}{3NHMe_2}$$

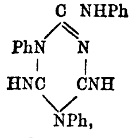
$$\underset{\text{alkyl-iso-melamine}}{(CNMe)_3 3NMe} + 3H_2O = \underset{\text{methyl-iso-cyanurate}}{(CO)_3 3NMe} + \underset{\text{monamine.}}{3NH_2Me}$$

Here was a distinction that could be observed, and experiment showed that the first equation represents the reaction which takes place. The new alkyl melamines are to be regarded, then, as normal derivatives, and the iso- structure is reserved for the metameric compounds derived from substituted ureas.

What, then, is the constitution of melamine itself? When the close analogy existing between the reactions by which the normal alkyl melamines are produced, and that by which melamine itself may be obtained is perceived, there cannot remain much doubt as to its normal constitution, thus:—

$$(CN)_3Cl_3 + 3H(NMe_2) = (CN)_3 3NMe_2 + 3HCl$$
$$(CN)_3Cl_3 + 3H(NHMe) = (CN)_3 3NHMe + 3HCl$$
$$(CN)_3Cl_3 + 3H(NH_2) = (CN)_3 3NH_2 + 3HCl.$$

Moreover the normal constitution of cyanuric chloride must not be forgotten. From it are derived only normal ethers, and from normal ethers, as Hofmann himself shows, cyanuric chloride may be reproduced by the action of phosphorus pentachloride. Two subsequent memoirs (*B.* 18, 3217; 19, 2061) contain a description of many new derivatives of normal and iso- cyanuric acid and melamine. Residues in the position which Rathke afterwards proposed to designate by the denomination *eso* are shown to exist in some of these complex derived compounds. This is notably the case with the triphenylmelamine which Hofmann designates unsymmetrical, and which Rathke would term diesotriphenylmelamine. It has the formula



and is composed of two iso-melamine and one normal melamine group. The cyanuric ethers were submitted to a careful re-examination in the first of these papers, and their melting-points and boiling-points re-determined and corrected, and in most cases their crystalline form submitted to exact measurements.

The question of the constitution of cyanuric acid was considered by Hofmann mainly in one of the memoirs already referred to (*B.* 18, 2791). It was pointed out in the first place that the constitution of the normal and iso- series of alkyl derivatives is established beyond question by the perfectly distinct products which they give when subjected to the decomposing action of water. The normal ethers break down into cyanuric acid and alcohol, the iso- ethers into carbon dioxide and amine. So far, then, as the decomposition of the ethers is evidence, cyanuric acid is a normal compound. But, on the other hand, no one has succeeded in preparing normal ethers from cyanuric acid. Iso- ethers, as in the methods of Wurtz and Habich and Limpricht, are always obtained. So far, then, as the formation of the ethers is evidence, cyanuric acid is an iso-compound. Consideration of these reactions leaves the question an open one. Other reactions must be studied. It is argued that cyanuric acid is iso- because of its formation from urea and certain allied compounds; but this assumes a constitution for urea which is by no means finally established; and which, indeed, as Hofmann points out, has been directly questioned. Again to cyanuric acid is assigned the iso- structure, because of its homology with cyanic acid, which is assumed to be iso-. If cyanic acid were really iso- this argument would have great weight; but Hofmann showed, especially by means of its close analogy to normal thio-cyanic acid, that cyanic acid is probably normal in constitution. It is admitted, however, by Hofmann that in order to explain all the reactions, whichever view be accepted, an intra-molecular rearrangement has sometimes to be assumed. For instance, maintaining the normal hypothesis such a change has to be supposed in the case of the reactions of Wurtz and Habich and Limpricht. It is shown, however, that instances of this change from normal to iso- are of frequent occurrence, whereas there is scarcely a case on record—only one which Hofmann himself in a later memoir pointed out—of the opposite change. This then is an argument in favour of the normal hypothesis. But perhaps the strongest of all arguments in support of the normal view is the relation of cyanuric acid to cyanuric chloride. This chloride is, for reasons already given, unquestionably a normal compound. Now phosphorus pentachloride behaves towards normal cyanuric ethers in a manner precisely parallel to its action, as shown by Beilstein, on cyanuric acid itself. In both cases cyanuric chloride results. Again, from cyanuric chloride and alcohol (sodium ethylate) normal ether is obtained, and in the parallel reaction between cyanuric chloride and water (sodium hydroxide) cyanuric acid results. Thus:—

$$(CN)_3 3OR' + 3PCl_5 = (CN)_3Cl_3 + 3POCl_3 + 3R'Cl$$
$$(CN)_3 3OH + 3PCl_5 = (CN)_3Cl_3 + 3POCl_3 + 3HCl$$

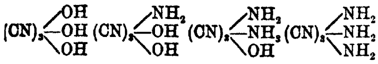
and

$$(CN)_3Cl_3 + 3R'OH = (CN)_3 3OR' + 3HCl$$
$$(CN)_3Cl_3 + 3HOH = (CN)_3 3OH + 3HCl.$$

This analogy receives important support from the corresponding thio- derivatives. It is scarcely conceivable that intramolecular change takes place in one series of these reactions and not in the other, and indeed the composition of the chloride of iso-cyanuric acid is probably such that it would be impossible for it by metastasis to be converted into cyanuric chloride; at all events Hofmann shows that the action of phosphorus pentachloride on iso- ether leads to the formation of a chloride having an altogether different composition. In another memoir in 1886 (*B.* 19, 2084) Hofmann continues this discussion. Klason in the meantime had offered another explanation of Rathke's dicyandiamide and thiocyanic acid reaction, which led to the normal and not the iso- structure for thio-ammeline. Hofmann adopted this. With regard to the use of more than one formula as suggested by Rathke, Hofmann can only admit this practice if it be meant to imply that a compound behaves in one reaction as if it had one constitution, and in another reaction as if its constitution were a different one. The identity of a substance requires that in its quiescent state it be regarded as one and the same thing. The only way out of the difficulty with regard to the constitution of cyanuric acid is to adopt that formula which explains the most reactions, and to assume in the others that metastasis takes place. Hofmann therefore adopts the view that cyanuric acid is a normal or hydroxyl compound.

There now remain to be considered a series of important communications from the Swedish chemist, P. Klason (or Claësson, as it is written in the Swedish memoirs). The field independently worked out by this observer is covered very largely by that of Hofmann, and has already been noticed. This is true also with regard to the view to be taken of the constitution of cyanic and cyanuric acids and melamine. The leading points which remain must now be briefly stated.

In an early communication in 1885 (*B.* 18, 496 R.) some important improvements were suggested in the preparation of cyanuric chloride, and the discovery of Cyanuric Iodide was announced. A series of normal melamines was described a little later (*B.* 18, 497 R.), and it was shown that thio-ammeline was normal and not iso-, as Rathke had maintained. Klason proved this by its synthesis from Liebig's chlorcyanamide (normal diamido-cyanuric chloride), by the action of sodium sulphydrate. The fact that cyanamide by polymerisation gives ordinary normal melamine leads to the view that it also is normal (*B.* 18, 499 R.). On the other hand Klason considered the only known series of alkyl cyanamides to be iso- compounds because they polymerise to alkyl iso- melamines. Maintaining the normal structure for cyanic and cyanuric acids Klason (1886, *J. pr.* 33, 126) submitted the reasoning of Nencki and the more recent arguments of Rathke to a detailed criticism. It was shown that another formula can be ascribed equally well to acetoguanidine, and that this leads to the normal formula for cyanuric acid. This is the case also with Rathke's reaction between dicyandiamide and thiocyanic acid, for Klason maintained that the diamide is a normal and not an iso- compound. The case of Bamberger's reaction is admittedly different. In order to explain that reaction, metastasis has undoubtedly to be assumed. Subsequent examination of the melam compounds by Klason (1886, *J. pr.* 33, 285) showed that ordinary melam is a mixture of true melam and a new compound melem, and that ordinary ammelide is a mixture of melanurenic acid and ammeline. It was therefore proposed to apply the name ammelide to melanurenic acid, in which case the compounds between cyanuric acid on the one hand and melamine on the other would be as follows:—



cyanuric acid ammelide ammeline melamine.

MONOCYANOGEN GROUP.

Normal cyanic acid CNOH *i.e.* (C:N).OH.

Formation.—1. By the action of heat on cyanuric acid (Wöhler, *G. A.* 71, 95; 73, 157; *P.* 1, 117; Liebig a. Wöhler, *P.* 20, 369).—2. In place of cyanuric acid a mixture of P_2O_5 and urea may be employed (Weltzien, *A.* 107, 219) or a mixture of uric acid with MnO_2 or H_2SO_4 (Döbereiner, *G. A.* 74, 121), or mercuric urate may be heated alone.—3. Cyanic acid is also formed when ethyl thiocarbamate is subjected to distillation. $CO.NH_2.SEt = CNOH + EtSH$ (Debus, *A.* 72, 1; 75, 127; 82, 253).

Cyanic acid cannot be isolated by treatment of its metallic or alkyl salts with hydrous acids or water, for the moment it is liberated it takes up the elements of water and appears as NH_3 and CO_2.

Preparation.—Anhydrous cyanuric acid is heated nearly to redness in a current of CO_2. This is conveniently accomplished in a tube bent at right angles, the charged arm of which can be placed in a combustion furnace. The vapour of cyanic acid is led into a suitable condenser surrounded by a freezing mixture. More or less polymeric cyamelide is always formed and condenses as a snow-white solid in the cooler parts of the tube (Wöhler) (Baeyer, *A.* 114, 156).

Properties.—A thin colourless liquid which reddens litmus and has an extremely pungent odour suggestive of glacial acetic acid. The vapour causes a copious flow of tears and the liquid applied to the skin quickly raises a blister. S.G. $(\underline{0})$ 1·140; $(\underline{-20})$ 1·156 (Troost a. Hautefeuille, *J.* 1868, 314). V.D. 1·50 (calc. = 1·49) (T. a. H.). H.C. 98,470 (T. a. H.). Cyanic acid changes readily into the isomeric cyamelide or 'insoluble cyanuric acid.' At 0° this transformation takes place quietly in the course of an hour, but at higher temperatures the action becomes explosive. The heat evolved by this atomic rearrangement is 17,630 gram-units (T. a. H., *J.* 1869, 99). In ice-water cyanic acid dissolves without decomposition until a certain degree of concentration is attained.
